## TO OUR READERS.

---

At this season our Dissolution also took place—a Volume closed; and we offered ourselves for re-election in this our thirty-third Address:—

“LADIES AND GENTLEMEN:—

“You have for so many years been so kind and so unanimous in giving us your votes, and you have from week to week so favoured us with your applause and support, that we are almost seduced into that delightful state of self-complacency which you have entitled another of your representatives in Fleet Street to assume. We do not, however, yet dare to evince Mr. Punch’s modest assurance, and must, therefore, once more announce our principles before we again venture to ask for a continuance of your confidence.

“Ladies and Gentlemen, we are altogether Ministerial, for that word has no meaning unless it is—serving usefully; and we are altogether in Opposition, because we wage war implacably against all bad practice. As heretofore, it will be our strenuous endeavour to lighten your burdens in every way, except descending to twopence as our weekly salary. We shall continue to tax as heretofore your incomes, for although the tea duty has been reduced, we do not find that either type, paper, or literary aid is thereby sensibly diminished in price. In fact, we never had any better hope, than that being able to put an additional spoonful into the pot might enable all those articles to be supplied to us stronger by the producers without any extra charge.

“Advocates of liberal measures, whether in the form of water, manure, or wages, yet we are staunch conservatives in devising Shelters, Mulchings, and Coal-consumers. In truth, we feel disposed to head a *new* party, and to call ourselves “Inclusives,” for we fraternise with many nations—Poland, Turkey, Bantam, Guinea, Spain, and Cochin-China, all share our pens. If we had been in the House on the night that the duty was taken off sugar, we should have scarcely known which swarm to have joined; for though it cheapens Bee food, it tends to reduce the price of Honey.

“For the future, once more we pledge ourselves to you, our Constituents, to continue our efforts to make your Paths smooth, your Nests productive, and your Honey abundant.”

Thus concluding, we made our bow, and grateful are we to acknowledge the receipt of the following “Report of Election:”—

“J. OF H. WAS ELECTED, BEING SUPPORTED BY ALL THE OLD AND MOST OF THE  
NEW CONSTITUENCY.”

# INDEX.

**ABERDEENSHIRE POULTRY SHOW**, 35  
*Acacia armata* leaves yellow, 238

LIBRARY  
NEW YORK  
BOTANICAL  
GARDEN.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 41.9°, and its night temperature 30.4°. The greatest heat was 54° on the 5th, 1844; and the lowest cold, 6°, on the 9th, 1841. The greatest fall of rain was 0.86 inch.

THE NEW YEAR.

AIN at last, and plenty of it too. The snow which fell a few days since, making one feel that pictorial representations of Christmas are not always myths, is altogether gone: one night's heavy rain has caused it to descend into the earth, and not a trace remains behind. The white landscape on which I looked but yesterday is wholly gone. Rain! rain! how it pours!

Just been to see old Widow Green, and took her some tea. How these little Christmas-boxes to the poor warm their hearts! Reader, are you in arrear with your Christmas-boxes? Go out this minute and distribute them until your conscience is clear. Never delay them—they have been looked forward to—talked over—reckoned on. If in money, it has been in idea appropriated to such and such an object—perhaps a red comforter a-piece for the boys.

Began my barrelled oysters last night, sent to me each year by dear old Mr. Dash. N.B.—He has all his life been fond of his garden, perhaps that accounts for his kindness of heart. N.B. No. 2.—Barrel heavy, but the oysters sat light; inference, they are good for digestion. N.B. No. 3.—Last autumn heard a respectably dressed man, a clerk in an office, call Asters "Chinese Oysters." He must have been, like the barrel, heavy.

Dear me! I have wandered in a maze and almost lost myself. I am quite amazed. Oh! the rain. Trudging, as I have been, on the slippery roads (Wiltshire roads bad, oh for Berkshire gravel!) a mile is a mile and a half now, because at each step you slip back half the way. I don't like walking in the rain. There is one's alpaca umbrella—the silk one I keep to lend to my lady friends. Silk is soft, suited to "velveted hands." (By the way, editors seem to like pats from velveted hands.) I lost two silk umbrellas so lent; but I still lend on in full faith, for the angels only steal—hearts. The rain comes through the alpaca in a fine dust-like drizzle; it spoils one's hat, and gets upon one's spectacles. I remember seeing a fat bishop of the old school—a Banting of a bishop—in great trouble. The good man was consecrating a church one hot day in July. The building was small, the congregation large. The poor bishop perspired profusely. The drops fell from his forehead upon his spectacles. He wiped them. Again descended the hot drops. And so he wiped and perspired, perspired and wiped in a frantic state, until, as he could not see, his chaplain had to read for him. My case

No. 197.—VOL. VIII, NEW SERIES.

was not so bad; but oh, the rain—how it finds out one's knees!

Home again—home again! What a blessing to have a home! Now never, good reader, especially if you read this in a gardener's cottage, never grow discontented and in a silly fit give up a settled comfortable home, though you may not have quite all you wish. Think if no situation turned up when you had to turn out, small lodgings, no room for the children to play, two removals, furniture broken, and other losses. Now take it kindly—I mean well. "Never give up a certainty except for a better certainty."

Oh this rain! But as out-door exercise is at an end for one day at least, I will anticipate the evening, though it be but afternoon yet, and in slippers ease enjoy myself. There, Gertrude darling, fairy-like child with the dancing curls, hand to me "Chambers' Book of Days."

Just easy, just happily settled, when the door opens, and I hear, "My dear, have you not forgotten to write something for the Journal on the new year? Last year's was not very ———."

"Please, Materfamilias, do not be hypercritical, though better than hypocritical, certainly."

"Well, you know I never flatter; but I think (of course what you call the humour was nothing) if you can do good and make people kindly that is very well; besides, some will be on the look-out."

"Well, I will try."

"There! the rain's over. What a glare of sunshine!"

(I do not like writing in a room facing the south). "There, please draw the blind down one pane, and I shall have one pain less."

I would, dear Editors and brother writers, that we could all dine together once a-year—at Christmas, for instance. I, the chaplain, would say grace. What glorious bouquets would be on the table—somebody would bring one for me, I flatter myself. Then the dinner should be *apropos*. Vegetable soup—no fish (except from Putteridge Bury). Then what turkeys! what poultry! what game! what vegetables! what a sweet course! gardeners and poultry-lovers doing their best. Then what Celery, and cheese made from cows that do not milk themselves. N.B., I would find bacon. Then what a dessert! There our pomologists would shine. What Apples, Pears, Grapes, &c.! Then the toasts and speeches! What a cheery evening it would be—what speeches! (I am thinking over my own at this time—three anecdotes in it). What talk, pleasant, clever, spirited! not a Gooseberry fool among the whole company. Then there would be the lady writers too—Fern-loving, and flower-loving and poultry-loving fair ones. Would not the wit be, like the flowers, brilliant and harmless?

Well, well, it is no use wishing; I must write instead of speak, though I prefer literally saying my say. Here begins. Brothers of the pen, Editors, and all! When I look through the Numbers of 1864 I am bold to say they are as good, or better, than their predecessors. Sometimes the gardening part may be the best, at other

No. 849.—VOL. XXXIII, OLD SERIES.

times the poultry part. That reminds me of a true story. A mamma and her young daughter sat down to play a duet at a party. They did not keep good time. A horsey young lady was present, who also had a correct ear for music; she was heard in a subdued tone to say to herself, "Ah! now the old mare's first—no, now the filly's first—ten to one on the filly—no, five to one—no, well done, they are both in level after all—capital, a dead heat." So of our Journal: a capital year, dead heat at the end.

On looking back through the past year, let me say a word about the ladies who have figured in our pages, made a better figure of themselves with their steel pens than their steel hoops, if I may be judge. First, thanks, personal thanks, to "FELIX-FEMINA." Never more will I say that I do not love Ferns, alleging that form without colour is unsatisfactory. "FELIX-FEMINA" has taught me better; whenever she writes she makes me a "Felix-mas." Oh, the pretty, graceful, fernlike sentences dancing like fronds in breeze and sunshine. She gives us an example how to make practical matters pleasing, giving details, but which cannot be called dry. Then her descriptions, too! One only fault she has—she makes me throw down the pen, dispirited, almost hopeless.

Nor have ladies alone excelled the gentlemen with quills, but with feathers too. Witness Lady Holmesdale and Miss Emily Beldon. I am no exhibitor, but could I be a Lady Holmesdale or an Emily Beldon all at once I would be. As a stalwart young Irishman, begging of me, said in reply to my question, "Why don't you enlist, a fine young fellow like you?" "So I would, if they'd make me a jeneral at once, your riverence." And I would be an exhibitor if I could be a Lady Holmesdale or an Emily Beldon at once. But, ladies, you make me despair. You have won your laurels, ladies, may you wear them long, adding each year fresh ones to your present full chaplets.

Looking back, and true to my character as chaplain (I was duly appointed by our co-archbishops at 17L, Fleet Street)—looking back through the Numbers of the present year, I must say that any little disputes have been carried on in a nice spirit; no hard words, sneers, or inuendos. My flock, I am proud of you. Sometimes I have seen in periodicals of former days disputes carried on in an acrimonious spirit, which have reminded me of an old story, the last it must be, of the days of my youth. An old doctor, long since dead, had a man servant named Solomon, wise in all things save where the beer was concerned. The doctor was at home alone, so he deemed, one Sunday afternoon. Presently he heard a singular noise as of a muffled voice and a running of some liquid. He traced the sound to the cellar, where he found foolish Solomon on his back, under a tap, quite drunk, with the beer still running on his face, and he solemnly saying, "No more, thank you sir; quite enough, thank you sir." Now, so should I say if a controversy became too lengthened, but I have not had to say so this year; but I should have said, "No more thank you," had there been a good reason, for my motto is, "Peace and good will to all," and among all.

And now, lastly, dear readers. Have we not done you good this last year? Gardeners in your cottages, for you shall be first addressed, as right you should, have you not looked forward to the day you receive our Journal? Have you not one foot, perhaps, rocking the cradle—

"Where alone with God the baby lies."

or nursing the said baby, a thing never to be ashamed of, for a baby is the best nursery plant I know—and you think so too—have you not read bits aloud to your wife, man, the good creature loving gardening for your sake, and you helping her with the little ones of an evening as you should, allowing her to ply her needle unencumbered for your benefit? Have you not had many a treat from our pages, taken, perhaps, a garden-plan, for which you had bright looks and praise, from your lady employers especially?

And you, younger ones, younger and more aspiring, have you not by studying our pages been fitting yourselves for higher positions? Be steady, good fellows, work on, read on, and—Now you won't mind the hint, will you?—"Do as little as possible on a Sunday."

Country gentlemen, ladies, clergymen, amateurs all of you, not forgetting that nice boy who keeps fancy pigeons and

rabbits, and got a prize at — Show,—I hope you have all felt drawn towards us this year, and that you welcome our Journal as a friend. We all need a hobby, it makes life going again to us. A man with a hobby has

"A young lamb's heart amid the full-grown flocks."

It drives away care and balances the mind; and what hobby is half so charming as flowers and birds? Good wishes to you all—a happy new year to you. I wish I could shake hands with you all; to "velveted hands," and horny hands too, I could give an equally warm grasp. But it cannot be—it cannot. I know you not by sight, I wish I did; so with my pen I must say farewell.—WILTSHIRE RECTOR.

## FLOWERS OF THE PAST SEASON.

### BEDDING PELARGONIUMS.

FOR a dry season such as we have had during the past summer, what can for a moment compare with the various sorts of Zonale or bedding Geraniums? While Verbenas mildewed and died off, Calceolarias would not grow, and Petunias were lanky and poor, the Scarlet Geranium as it is still called (although now to be had in white, pink, crimson, and other colours), kept its ground, and, if not growing quite so vigorously as in ordinary seasons, certainly bloomed as well. It is no wonder, then, that the caterers for public taste should endeavour to meet the increasing demand by increasing attention to their hybridisation; and hence it is that we may truly say the name of them now is legion. But there are some mistakes made on this point which I would remind our friends of. It is not enough that a new variety have a larger or more brilliant flower than others in the same class, if it have not a habit correspondingly good. I have flowered some remarkably fine-looking sorts this season; but then their habit was so gross, and the trusses so sparingly produced, that they were utterly valueless. Again: where there is no peculiar marking to make a distinction between sorts, a flower may be very good, but so strikingly similar to others already in cultivation as to puzzle any one to decide as to the difference. Thus, I have had several this year so like Herald of Spring, that although individually good, they are not worthy of being retained where the older, cheaper, and equally good variety is to be had. Nor let it be forgotten that some sorts, although of very little use for the parterre, are very valuable for the greenhouse; and growers would do well, I think, in announcing their novelties, to say for which they are suitable. There are many which are equally good for both purposes, while some are only fit for one. It is utterly impossible that even in the most extensive gardens all these varieties can be grown, and therefore a weeding process must be adopted. No flower is, perhaps, more widely cultivated than this—in the wilds of dear and stormy Donegal, and in the brilliant masterpieces of gardening at Linton or Shrubland, it is alike cherished. Let us not lose anything of our enjoyment by being distracted by the crowd of new faces, when we have many times to say the old are better.

### VARIEGATED-FOLIAGED VARIETIES.

Several of these have come under my notice this season, but in the beautiful section where Mrs. Pollock has reigned supreme I have not seen as yet any that surpass that exquisite variety; and I think that whatever slight difference of marking there may be in some of those I have seen, such as Mrs. Benyon, yet for habit and other qualities combined Mrs. Pollock still stands unrivalled. In the Tricolor Silver Variegated varieties a good and beautiful addition has been made in Italia Unita, sent out by Messrs. E. G. Henderson and Son. This class make excellent pot plants, but, unlike the Golden Variegated, they do not prosper well out of doors.

### WHITE-FLOWERED VARIETIES.

We all recollect what a terrible warfare (on paper) there was about the new varieties of white-flowered Pelargoniums that were to come out last spring; "a very pretty quarrel" indeed, but one that might have been very well spared. My own opinion of them all may be illustrated by the reply made to me by a well-known grower. "Well, Mr. —, what do you think of these new white Geraniums?" "Think! why, that I could execute any amount of orders for them

from my stock of Madame Vaucher." Madame Barillet, the French variety that I saw, is perhaps a little more free-flowering, but that is all. For bedding purposes these flowers are of very little use. Rain soon soils their purity, while the sun turns them of a dirty blush. As pot plants they are very valuable, and they do excellently for cutting for bouquets.

SCARLETS OF VARIOUS SHADES, PINES, &c.

\**Glitter* (Bull).—A good scarlet, bright flower. Very brilliant, and likely to prove useful.

\**Excellent* (F. & A. Smith).—A very free-flowering variety; strong horseshoe; light scarlet rose flower, well-formed; of good habit.

*Nonsuch* (Bull).—Rose; horseshoe leaf, but the flower and truss too small.

*Elegance* (Bull).—Violet rose. Pretty, but too much like Herald of Spring.

*Blushing Beauty* (Bull).—In the style of Prince of Hesse, and no better. Good horseshoe foliage.

\**Lorenzo* (Bull).—Very large pip and truss, scarlet; good and well-marked foliage. An excellent variety.

*Loyalty* (Bull).—Vivid scarlet, but too gross in habit to be worth anything.

\**Miriam* (Bull).—A very pretty rose-coloured flower; habit of plant vigorous; free-flowering, colour novel.

*Purity* (Bull).—White-flowered. No better than Madame Vaucher.

*Regalis* (Bull).—Salmon rose. Something in the way of Herald of Spring.

*Vivid* (Bull).—A very bright scarlet, large truss and pip; but I fear the habit is too gross ever to make it valuable.

\**Eve* (Bull).—Pretty, pink shaded with white, and very promising. It has received a first-class certificate.

*Celestial* (Bull).—Too gross, and not free-flowering.

*Striking* (Bull).—Like Diadem and Madame Rudersdorff, but not equal to those varieties.

*Brilliance* (Bull).—Too gross in habit to be of any value.

*Provost* (Bull).—Too much like Herald of Spring.

\**The Clipper* (Bull).—An excellent flower, and one well worth growing. Its habit is good, and the flowers large and round. Colour bright scarlet.

*Effie* (Bull).—Truss too small.

\**Charmer* (Bull).—A flower somewhat in the style of Eve, and, like it, will be useful. It is, perhaps, somewhat more robust than that variety.

\**Lord of the Isles* (G. Smith).—Crimson scarlet; large and well-formed. Of good habit.

*Orange Globe*.—Orange scarlet, white eye. Good habit.

\**Eugénie Mésard*.—Bright salmon, shaded and spotted with white. Very pretty.

\**Culford Rose*.—Brilliant carmine salmon; flowers large, well formed. A good trusser.

*Louis Schweitzer*.—Salmon-coloured flowers, white centre; truss good.

\**Lady Cowper* (Francis).—A perfect little gem, and quite distinct from anything I have seen. It does not grow above 7 or 8 inches high, is very free-flowering, the flowers bright scarlet, and as an edging for scarlet beds invaluable. Its leaf is so small and fine that it hardly looks like a Geranium.

\**Loyalty* (Williams).—A bright scarlet flower. Habit of plant good.

There can be, I think, little doubt that in some of the foregoing varieties we have advances on anything previously out. There is a size and form amongst many of the Scarlets, combined as these qualities are in some of them, with good habit, that will not fail to recommend them for general use. Such flowers as Excellent, The Clipper, Lorenzo, &c., will, I am assured, be general favourites. The season not having been a favourable one for determining the merits of any bedding plants will justify one in not deciding positively against a flower; but I am inclined to think that those marked with an asterisk will be found the best in each class. In this as in every other department of horticulture there is progress; while at the same time there are many things sent out which only the partiality of the raisers can see any beauty in beyond those already in cultivation.

While on the subject of Scarlet Geraniums I cannot forbear saying another word about the plants that appeared at our metropolitan exhibitions this season. They were quite, to

my mind, unworthy of the well-known skill of our growers. Anything more frightful than some of them were, it is impossible to conceive. In some the trusses were tied right across, so that stakes and stalks met the eye in every direction. Other plants were trained table fashion, as plants of Pompon Chrysanthemums sometimes are; and in very few was there that appearance of neatness and symmetry, which it is very easy to give to a Scarlet Geranium. If there be any competition this season, let us hope to see more natural plants.—D., Deal.

FRUIT IN THE NEW YORK (AMERICA) MARKET.

NEW YORK is abundantly supplied with a profusion of various sorts of fresh fruits nearly all the year round, and from the number and quality of indigenous varieties, as well as proximity to the West Indies and other regions favourable to pomological development, she enjoys advantages in this respect over most of the European cities. Amongst the earlier arrivals come shiploads of Bananas and Pine Apples. The Bananas are very fine, and are imported all hanging in huge clusters, just as they come from the parent tree. They are retailed as cheap as two cents, a single fruit, finer ones, of course, dearer in proportion to quality, and are extensively used during the prevalence of the hot weather, when large quantities of ripe fruit can be consumed without detriment to the system. Amongst Pine Apples I noticed chiefly the Black Jamaica and Montserrat, with a good sprinkling of Smooth Cayennes and a few Providences. They are sold from 5 cents, upwards, very fine fruit to be had for a quarter of a dollar, equivalent to an English shilling.

Strawberries come in about the end of May, and beginning of June, and for three weeks or a month reign supreme, to the exclusion of almost all other fruits, and owing to the extreme heat then prevailing, the Strawberry season only lasts for that period. The same cause also detracts materially from the flavour of the Strawberry, the very rapid maturing process undergone, operating, at least, against the juices of this fruit being highly perfected; but as they are seldom eaten singly, and never sent to table as gathered, any deficiency of flavour is not easily detected when "smothered in crame." Strawberry-growing for market has been gone into most spiritedly, the principal grower in the States, Mr. Knox, of Pittsburgh, Pennsylvania, rejoicing in the regal title of the "Strawberry King," and long may royalty be thus honoured. Many varieties, such as Keens' Seedling, British Queen, and Sir Harry, do not thrive well; but again some others, such as Triomphe de Gand, Victoria, La Constante, &c., seem to have a more adaptable constitution, and bear abundantly. The favourite market variety, and the most prolific bearer I ever saw, is a seedling raised in this country, called Wilson's Albany. It is a little acid, unless when dead ripe, but a valuable Strawberry for preserves. Triomphe de Gand has risen rapidly in favour, and bids fair to be a standard fruit.

Small fruits, such as Currants, Raspberries, Cranberries, Whortleberries, Blackberries, &c., are supplied in immense quantities, the Blackberry being a great favourite, and deservedly so. One variety, the Lawton, is cultivated extensively and profitably; it is a large fruit, a free bearer, and answers admirably for either dessert or preserves. Made into what is termed Blackberry brandy, it is highly prized as an antidote to many disorders incidental to a hot climate, and I heard one energetic, demonstrative lady tell how this summer, instead of idling away her time at a fashionable watering-place, she took up her quarters in what is termed the Blackberry country, in New Jersey, made seventy-two gallons of Blackberry brandy with her own hands, and forwarded it direct to the armies in the field, where she trusted it would be the means of alleviating some suffering—a most notable instance of how far active benevolence transcends passive sympathy. Cranberries are cultivated extensively, and are highly prized by housekeepers for pies, puddings, preserves, &c., one company having a patch of 25,000 acres in one location in New Jersey, for their production, and having lately taken in another 10,000 acres for the same purpose. Mr. Tillyard used to exhibit good dishes of the American Cranberry at the various London shows,

and they formed valuable auxiliaries to his collection of fruit; but they do not seem to have been grown to any great extent.

The market has been fairly flooded this season with Peaches; for several weeks a daily supply of from 40 to 45,000 baskets was calculated to have reached this city, each basket containing nearly a bushel. They come principally from the States of Delaware and New Jersey, having as a rule most doggedly refused to ripen around New York for some years past. The Peach is grown in orchards just as you will find the Apple growing in the Carse of Gowrie, or Devonshire, but the fruit generally averages small, and lacks the luscious richness of the cultivated varieties grown out of doors, from Sutherlandshire to the Isle of Wight. This deficiency of flavour is the natural result of the quantity grown, as the same attention cannot be paid as at home, where every individual fruit receives especial care, no superfluous foliage being allowed to shade it from the sun, or noxious insects prey on its vitals.

Nectarines are not known except to professionals, and the few Apricots that I have seen were poor. Plums are very fine, and reach market in large quantities. I noticed some old acquaintances amongst them, such as Green Gage, Damson, Jefferson, &c. Both Musk and Water Melons are supplied in immense quantities, and a fine sight during the prevalence of the hot weather it is to see this deliciously grateful fruit piled up on the stalls in thousands, a supply of Water Melon being kept cut up ready to quench the thirst of hurried passers-by, for the small sum of 5 cents. The Musk Melons are retailed from 10 cents, a-piece, and were even finer and more plentiful this season than ever.

Grapes, both native and exotic, are first-class. The fruiterers have the exotic varieties nearly all the year round, comprising those which are so well known to the horticultural public, and as their cultivation is in the hands of professional gardeners, this is sufficient guarantee of their excellence, and could distance be annihilated, many of the London exhibitors would have to look out for their honours. Having been free from mildew, that scourge of Grape-growing districts, the native Grapes were even finer this season than usual. The principal varieties at market were—Concord, Hartford Prolific, Delaware, Diana, Rebecca, and Catawba, the Isabella being now nearly superseded. The Catawba is principally cultivated for its wine-producing qualities. I should think most of these varieties would do well in the south of England, where the Sweetwater ripens so well, and often when admiring the fine bold outline of the terraces at Ponthill from the opposite slope, I have thought what a fine vineyard might be made along their front, where Mr. Beckford shaped beauty out of barrenness, and the present proprietor, the Marquis of Westminster, has done so much to renovate the place, and improve the condition of his workmen.

Pears are now quite an American institution, most of the fine varieties growing freely as standards, there being no such thing as garden walls for fruit trees here, for gardeners to show their skill and waste their time, in training trees in all manner of impossible ways, a simple picket fence generally doing duty as an inclosure. Neither Jargonelle, Marie Louise, or Easter Beurré, do much good, but they are almost the only exceptions I know. Williams's Bon Chrétien, under the popular name of Bartlett, is the great market fruit, and I have seen the trees literally loaded to the ground with large, finely developed fruit, and as an instance of the prolific properties of the Pear here, I have seen fine fruit of Duchesse d'Angoulême selling for a cent. a-piece; but this is by no means a common occurrence. The following are to be found in every collection of Pears deserving the name, and are all reliable varieties in this climate—viz., Doyenné d'Été, Kingsessing, Beurré Clairgeau, Beurré Diel, Beurré d'Anjou, Seckel, Beurré Gris d'Hiver Nouveau, Belle Lucrative or Fondante d'Automne, Doyenné Boussoch, Doyenné Siculle, Virgalieu, Flemish Beauty, Louise Bonne of Jersey, Onondaga, Urbaniste, Glou Moreau, &c. As a rule most of these varieties thrive much better on the Pear than on the Quince stock.

The Apple also comes in for its share of public patronage, and well does the famous Newtown or Fall Pippin deserve its name, as it makes both a first-rate dessert and good cooking Apple. The Baldwin, Spitzenburgh, Astrachan, and

a few others, make their annual appearance in the market, but all fall immeasurably short, in point of merit, of the Newtown Pippin, as no housekeeper will use any other while she can get this, a very sure test of the general utility of any variety of fruit.—DAVID FOULIS, *New York, December 12th.*

### THE SOMERFORD VINERIES—DISTANCE BETWEEN VINES.

IN Mr. Q. Read's report on the Somerford vineries in your Journal of the 6th ult., it is stated that the back walls are planted with different Vines, and that these bore fruit nearly down to the ground.

Presuming the houses to be of the lean-to form of the ordinary dimensions, about 15 feet wide, and about as much high, the canes on front rafters being planted as usual and trained on the spur system, my question is, Whether the Vines on the back wall will have light and sun enough, so as to be still fruited downwards, when the front Vines are full grown?

I am an amateur fruit-grower, principally of Vines, and am just about erecting two other lean-to vineries. In my former houses I made use of the back wall by training some Vines almost up to the top, and then dividing them into two horizontal branches, as in the Montreuil mode of training. In this way the Vine catches the top light and thrives very well, but a great part of the lower wall is entirely without fruit. For this reason the Somerford-way is to be preferred if the lower parts of the stem really receive light enough for fruiting well. Then I have another question to ask. I find the distance at which it is generally recommended to plant Vines in a Vine-border is 2½ or 3 feet; I never planted them nearer to each other than 4 feet, and even with this distance the laterals, although on the proper spur system, almost meet. Now, with closer planting they must partly cross each other, even with close pinching-in. I should, therefore, like to know whether 3 feet is really the distance generally adopted in England?

Allow me, before concluding, to remark on a notice in your paper the other day regarding the Black Hamburg grafted on the Chasselas Musqué. I practised this five years ago with very fair success. The growth is rather strong on this stock; the bunches and berries are large, but lighter-coloured than those of another Vine on its own roots; the skin of the berries, however, is more tender, the flesh very sugary, but of rather less flavour.—JOHN W., *Hamburg, Germany.*

[In reply to your German correspondent's very reasonable question, I wish to say that the vineries at Somerford Park are not ordinary lean-to's, but what may be termed nearly half span-roofed. The inside dimensions of the houses are as follows:—Width, 15 feet; height of back wall, 10 feet 3 inches; front to the underside of the rafter, 4 feet 6 inches; height to the ridge, 12 feet; with a north light 4 feet 3 inches in length. The Vines in front are 4 feet apart, and are planted on the inside, but provision is made for the roots to go outside when the inside border becomes somewhat exhausted, the front wall being arched for that purpose. The Vines at the back wall are planted 5 feet apart, and two rods are taken from each Vine, thus making the rods 2 feet 6 inches asunder, and at the time of my visit the lowest bunches on these Vines were 2 feet 6 inches from the ground.

Now, I consider there is a very considerable advantage in a house of this description over an ordinary lean-to for planting Vines at the back, as 4 feet of rafter and 4 or 6 feet of the back wall can be relied on to produce good Grapes after the Vines have reached the top and become established. It is not to be expected that the Vines will continue to produce good fruit so near the ground as they have done this year, but about one-half of the back wall may be depended on as being productive.

I do not wonder at your correspondent's back wall in his ordinary lean-to vinery being unproductive, but I should expect his branches trained horizontally near the top, not only to grow well, but also to bear plenty of fruit, provided the Vines are in a healthy condition.

With regard to the distance Vines are planted apart, it is now becoming almost general in England to plant much closer than formerly, and there is no objection to their being

2 or 2½ feet apart. I planted a small vinery about a fortnight ago. (In the following compost:—to every five or six barrowful of turf from an old pasture, I add one barrowful of old mortar rubbish, to that nearly one barrowful of ground oyster shells, and to the above another barrowful of ground bones and woollen waste, the latter procured from a woollen manufactory.) I have planted them 2 feet from plant to plant, that is one to go up the rafter and one up the centre of each light. In order not to be overcrowded with branches we shall disbud freely, and regulate the spurs at the winter pruning, and where we should have two spurs on rods 4 feet apart, we only require one when only half that distance. If you expect to take a given quantity of fruit from each light of a vinery, it is much better to take it from two Vines than one, you have double the quantity of roots to produce the same weight of fruit, and consequently the Vines do not so soon become exhausted.—Q. READ.]

### POINSETTIA PULCHERRIMA CULTURE.

PROBABLY no plant in cultivation is more ornamental during the winter months than *Poinsettia pulcherrima*—that is, when it is well grown. Even under indifferent culture it is ornamental from the brilliant colour of the terminal bracts. It is also one of the most accommodating of plants, as scarcely any amount of ill-treatment or neglect, with the exception of an unsuitable temperature, will destroy it or prevent its blooming in its proper season. It will bloom freely as a large plant, or as a very small one, thus accommodating itself to a large conservatory or shallow pit.

No one who is desirous of having a really ornamental plant, and can command a winter temperature of from 50° to 70°, need despair of cultivating this *Poinsettia*. During the summer a rather close greenhouse is all that is required to start and keep it growing; but to give my own experience of its culture in a connected form I will begin at the beginning.

In order to have a large plant of it, take a plant that has flowered, keep it rather dry, in a temperature of about 50°, until April or the beginning of May, and when in a temperature of 60° it will most likely begin to start into growth. It may have been previously cut down to within about 8 or 9 inches of the collar, or it may be cut according to the manner in which it breaks, so as to leave three, four, or more shoots. When it has made two or three leaves turn it out of the pot, pull off some of the old roots, and shaking out some of the old soil, put it in a pot a size larger than it was before, using a mixture of equal parts of peat and loam, with sufficient sand to make the soil porous. Place the plant in a stove or hotbed, and it will soon take to the new soil, and show roots through the bottom. When this is the case it may be shifted into a 12 or 13-inch pot, in which it may be allowed to flower, unless it is desired to have a very large specimen, when it may have a third shift about the end of July into an 18-inch pot, using the same kind of soil, and bearing in mind that a slightly increased temperature is advantageous after each potting. When, however, it has taken good hold of the soil after the last shift, a vinery or rather close greenhouse will suit it very well until the middle of September, when it should have a temperature never under 50°, and an average of 60° would suit it much better. It may then have an occasional dose of liquid manure, say twice a-week. I forgot to state that the points of the shoots may be stopped about the time of the second shift; this will cause two or three shoots to be thrown out from each. From the end of July it will grow rapidly until it begins to show the scarlet bracts, which will be about the beginning of November, and at Christmas it will be in its prime. It may be permitted to bloom as long as it will, and may then be gradually allowed to become dry, and rest, taking care, however, that it is not overdried. When the time arrives for starting it again it may receive the same treatment as before. It is better to take a smaller plant to make a large specimen the next season than to take the same plant, which would have to be reduced nearly to its original size, or treated after the manner of a specimen *Geranium*.

Many prefer having plants in small pots with a single head of bloom on each; and where there is no convenience for growing large plants this is the best way. Under any

circumstances such plants are useful for decoration, and make capital plants for the dinner-table.

In order to obtain them one or more old plants are necessary to cut from in May, when they have had their rest, and been started into growth. The shoots being 3 or 4 inches long, are taken off, and placed in small pots in an equal mixture of peat, loam, and sand, and plunged in a brisk bottom heat. When struck they may be potted in four-inch pots, and shifted from them to six or seven-inch pots. They will not branch, but the freer their growth the larger will be the head of bloom on each. They may be had still smaller by starving the old plants until later in the season, and taking off the shoots in July, potting them singly into thumb pots, and when rooted shifting into four-inch pots, in which they will bloom. The plants will be small, and the flower in proportion; but they will be as ornamental and effective for decoration as can well be conceived. I have known them so grown in large quantities for Covent Garden Market, and a prettier sight than such large masses could not well be imagined; in fact, *Poinsettia pulcherrima* is a plant that will always reward the cultivator, whether grown simply for decorative purposes or for profit.—F. CHITTY.

### MANAGEMENT OF ROSES IN THE NORTH.

I HAVE read with much pleasure Mr. Radclyffe's letter, in page 468, and beg to thank him for the advice it contains. I find that I have now most of the varieties recommended, including those mentioned in a subsequent paragraph. I have also many others, and hope to be able, next season, if all go well, to add a few to the list with which he has favoured us. In the meantime I think the following, which are not included, will not disappoint growers in the north, at least, so far as the opening of their flowers is concerned—viz.:—Catherine Guillot, Madame Vidot, Duchesse de Cambacères, Lord Raglan, Buffon, Empereur de Maroc, Cardinal Patrizzi, Safrano (T.), and Comtesse Murinais (Moss).

As regards the particular merits of the above, I must allow amateurs to judge for themselves; but I may be permitted to observe, that where such Roses as Madame Vidot, Catherine Guillot, and Lord Raglan can be grown successfully, they should never be omitted, however small the collection may be. Nothing in the form of a Rose could surpass the first of these as it bloomed with me this last season. I know that in some instances it has failed to give satisfaction, but while I can obtain a single bloom, such as it produced here, I will endeavour to find a place for it. The other two I saw in flower at a place about thirty miles to the west of this, at an elevation of nearly 700 feet above Loch Ness, and of which it may almost be said that, when it ceases to rain it commences to snow; there cannot, therefore, be any doubt as to their being suitable to the wants of northern growers.

I now beg to refer to the concluding paragraph of Mr. Radclyffe's letter, and I trust he will pardon me in pointing out a slight mistake which he appears to have made. He says—"Celina is only fit to bud upon." (Probably meaning at the time the H.B. Celini). By referring to page 436, he will find that the variety I make mention of is the Moss Rose "Celina," which I do not for a moment suppose he would recommend for such a purpose. I was glad to find that I had treated Auguste Mie and Victoria in accordance with his directions, which I trust may have the desired effect.

I will now with your permission, reply to the observations of "A SUBSCRIBER, Aberdeen," and endeavour to supply the information requested, but in the first place I beg to state, in reference to the cultivation of the Rose, that although certain fixed rules are laid down for our guidance, it does not follow that the same treatment will answer equally well in all situations. Where there is pure air, deep loamy soil, and good drainage, it is pretty plain sailing, but in the absence of these essentials, it becomes necessary for us to exercise a little of our own judgment, and it is astonishing sometimes what a person can accomplish when guided by a little common sense. I would remind my brother amateurs, that it is not where everything goes on smoothly with us that we learn most. No, the little difficulties we frequently meet with are oftentimes our best instructors. As an instance of this, I beg to refer them to the letter of "ALIQUI," at

page 411, from which we may all take a lesson; but I find I am digressing, I will, therefore, proceed at once to answer "A SUBSCRIBER'S" inquiries. In the first place, then, he will observe in the third paragraph, page 436, that I give the preference to the Manetti stock budded and planted deeply—that is, with the junction of the bud with the stock 2 inches or so under the surface. In the second place, the only additional information I can give respecting the Rose is, that it is generally known here under the name of the "Maiden's Blush." Should he not be able to find it under that name, I have no doubt the description I have already given of it will lead to its discovery in one or other of the cottage gardens in his neighbourhood. I may, however, inform him, that I intend using this as a stock cautiously—hasty conclusions are dangerous sometimes—it is all that I have said of it, but I have since observed that the stem does not increase in size in proportion to the head; consequently, the bark may in time become indurated, and we may, in a year or two, find the heads beginning to assume a sickly appearance, and ultimately dying off altogether. If, however, it should turn out all right in this respect, I am still of opinion it will beat the Briar.

I will now describe the manner in which I treat my Roses generally, and leave "A SUBSCRIBER" to judge for himself as to whether such treatment may be suitable to his circumstances. First, then, I must tell him that nearly all my dwarf plants are in two borders by themselves, the second border is a continuation of the one I have before described. I find that they contain just seventy plants, and as many varieties. In other parts of the garden there may be twenty or thirty more, but here let me state, that I do not approve of growing so many varieties in a small collection when not intended for exhibition purposes. A third of the number in my opinion would be quite sufficient, but I am groping my way, and doing it in order to find out what are most suitable to the climate, but to resume. About the beginning of the present month, having received two or three dozen fresh plants, I made a complete re-arrangement of my borders, that done I staked each plant firmly, after which I mulched the whole with pig manure, about 4 inches thick, taking care to keep it an inch or two from the stems of the plants. I then covered the whole with long heather to the depth of about 1½ foot laid on very loosely, which in my opinion is much better than fern for the purpose, as it allows the air to circulate more freely which is of great importance. The whole of the above are either on the Manetti or dwarf stocks of the Dog Rose, although I certainly prefer the former. Some of them do very well indeed on the latter, but it must be borne in mind that deep planting does not suit this description of stock. My practice is to have the crown from 2 to 3 inches under the surface. Of standards I have but few of last year's budding, in consequence of a number of the buds having been destroyed by an insect. They are all under bud this year and looking well, and I hope, after the warning I have received, to carry them through safely. I have each bud protected with a piece of oiled paper (old newspapers brushed over with boiled oil and allowed to get dry), contracted at one end and tied firmly round the shoot above the bud, leaving sufficient room underneath. This does not, like hay or other soft material, retain moisture, which in my opinion is more injurious to dormant buds than frost. All these as well as the dwarfs are firmly staked and mulched, with a little heather placed round their roots as well. The heads of standards, especially the moderate and dwarf-growing varieties, I protect by placing around them and amongst the shoots a few branches of heather, and tying the root ends firmly round the stake, giving them the appearance of so many inverted brooms. So much for protection, now for the removal of it. Well, about the beginning of March if the weather be favourable, I take off one-half of the heath and the remainder about the middle of the month. I then in a few days afterwards remove the manure from the surface to the kitchen garden, that done I prune the whole, trim up the borders, and make all look tidy. I have now nothing to do, with the exception of attending to them as occasion may require with weak guano water, of which I have always a cask at hand, or other liquid manure, but to watch the progress of the plants and admire their beauties when in bloom.

Such is my mode of treatment, and if I am wrong in any

particular, I trust for the sake of others as well as myself, that I may be put right by my valued instructors in THE JOURNAL OF HORTICULTURE.—LOCH NESS.

P.S.—A hint as to the best way of stopping the insect, to which I have alluded, from committing such havoc among the buds, will oblige.

### TRENCHING.

I FIND that ground can be dug thus, at about one-third the expense of digging all the ground, and left in a much better state for the action of frost.

The land also remains dry. You will perceive that only one-third of the ground is removed.—A CONSTANT READER.

[If exposing the soil to frost and other atmospheric influences is all that is required, the above plan is available, but not if the objects are either to deepen the soil, or bring the lower stratum to the surface.—EDS.]

### PEARS ON THORN STOCKS.

WITH reference to the communication with this heading in your Number for 27th ult, I may mention that in the garden at Preston Hall, near Dalkeith, in the county of Edinburgh, there is an old Muirfowl's Egg Pear tree grafted on the Hawthorn, now in perfect health, and which bears fruit of excellent quality.

The gardens at Preston Hall were laid out fully three-quarters of a century since by the late Mr. Hay, who was then gardener there, and who afterwards practised in Edinburgh with considerable success as a garden architect, and the tree in question seems to be one of those planted when the garden was formed.

I may mention that I some years since sent a basket of the fruit to a meeting of the Edinburgh Botanical Society, and the members present declared them to be "excellent," as well as "interesting." I have tried a good many Pears on the Hawthorn stock, some of which are now more than ten years old, and all have invariably done well.—WILLIAM GORRIE, *Bangholm, Edinburgh.*

### GARDENERS DURING ILLNESS.

ARE there any rules for paying gardeners during sickness? I mean, is it a gentleman's duty to pay his gardener when he cannot attend work through being sick? I should very much like to know.—E. B.

[We regret that we cannot give any definite reply. The "duty" of a gentleman to pay his gardener when from sickness unable to attend work, must ever remain a question of principle and of feeling, rather than of right and duty. Something will, no doubt, depend upon how a servant is hired—domestic or out-door, and whether he is a yearly weekly or monthly servant. To the credit of our gentry, the most of them, when a servant is ill, will pay for a time, and may also secure medical help. We have known servants accept all this as merely a matter of course, and not as a subject to be grateful for, yet such treatment spontaneously arises from generous and kindly feeling. If there should be any legal right to such payment, that must be much lessened in the case of out-door servants. In their case the only appeal would be to kindness rather than mere duty. Most employers of gardeners treat them kindly on such occasions; but that is different from a gardener setting up any claim to it as a right. We have known cases, but they are few, in which great cruelty was exercised, such as giving a man notice to quit when unable to turn himself in bed; but in most cases much sympathy and kindness are manifested, and this is sure to be an advantage to both in the end. Suppose a thoroughly good gardener to have his wages stopped for a week's illness, though he had served his employer early and late, we know he would resolve to stay with such an employer only as long as it suited him. The very changing of servants, even though the old and the new might conscientiously do their very best, would soon make havoc, from the very change, with more than

would pay the wages of some weeks' or even months' illness. However, in all such cases the servant will act wisely if he seldom thinks, and never speaks, of his own "rights" and his employer's "duties." We have known otherwise clever men reason themselves into strange fancies, until they became morbidly aggrieved and injured. We believe that gardeners, like other workers, must, as a matter of course, be able to work in order to receive the stipulated remuneration, yet very few gentlemen run close in this matter; and of all servants none are more worthy of kind consideration than gardeners.]

### ORCHIDS IN FLOWER IN DECEMBER.

THIS short list may prove interesting to some few of the many lovers of Orchids, as we like to know what plants flower at this dull season. I think winter-flowering Orchids are worthy of more notice than is usually bestowed upon them, as they enliven the dull winter months, when there is little of interest to be seen in other departments. It would be useless for me to attempt to describe the many beauties of this beautiful tribe of plants. We have now in flower *Angraecum sesquipedale*, with its ivory white flowers 5 inches across, with a great tail 12 inches long; *A. eburneum superbum*, *Ansellia africana*, *Barkeria Skinneri*, *Burlingtonia amoena*, *Cattleya amethystoglossa*, one of the most beautiful *Cattleyas* in cultivation; *Calanthe Veitchii*, a beautiful winter-flowering plant with a spike 4 feet long, thickly set with its beautiful rose-coloured flowers; *C. vestita rubrooculata*, *C. vestita lutea*, *Celogyne fuscescens*, *C. species*, *Cypripedium hirsutissimum*, very fine, with two flowers on each spike; *C. Fairrieanum*, *C. barbatum nigrum*, *C. insignis*, *C. venustum*, *Epidendrum vitellinum majus*, *E. amabile*, a magnificent variety, one that will become a general favourite when known; *Galeandra Stangeniana*, *Ionopsis paniculata*, *Leptotes bicolor*, *Lelia acuminata*, *L. anceps*, *L. autumnalis*, a beautiful variety; *L. praestans*, *Lycaste Skinneri*, in varieties; *Maxillaria venusta*, this has been in flower six months; *M. picta*, *M. picta majus*, *Miltonia Morelii atro-rubens*, *Odontoglossum Inseleyii*, true; *Oncidium Cavendishii*, *O. Suttonii*, *O. pulvinatum majus*, *O. sphacelatum*, *O. species*, *Phalaenopsis amabilis*, *P. grandiflora*, *Saccolabium miniatum*, *S. violacea*, *Sophronites grandiflora*, long and round leaved varieties; *S. cernua*, *S. violacea*, *Phajus maculatus*, *Trichocentron Pinelli*, and *Zygopetalum crinitum*.—E. MITCHELL, Gardener to R. F. Ainsworth, Esq., M.D., Lower Broughton, Manchester.

### USES OF COCOA-NUT FIBRE REFUSE.

IN a recent Number of the Journal you made some remarks respecting potting *Camellias* in cocoa-nut refuse, and have rightly recommended it to be mixed with loam. I think many persons use too much of the refuse for hard-wooded plants, which generally thrive best in good loam with very little peat or leaf mould—no more than is sufficient to keep the soil open and prevent its binding too closely together. The refuse may be substituted for the peat and leaf mould. I planted an old sickly *Camellia*, that had not flowered for three or four years, in mould mixed with about one-fourth of the refuse, and put more than one-half closely around the roots; the plants afterwards grew vigorously and blossomed well. For *Rhododendrons* and American plants it may be used more freely.

Whenever I replant trees or shrubs of any kind, I use some of the refuse, alone or mixed with the mould, to spread thinly about the roots, as it causes a rapid production of fine fibrous roots, which afterwards find their way into the loam most suitable to maintain their growth.

At the end of December last year I planted some *Roses* and dwarf *Pear* trees on the quince stock in my garden; but having no dung, and the soil being rather stiff and poor, I used the refuse as I have just described, and then mulched them with the refuse only, 5 or 6 inches deep, which effectually protected the roots from severe frost. Every tree grew vigorously and some bore fine fruit. However, as the refuse will not support the continuous growth of trees like stable manure, I determined to follow the advice of Mr. Rivers in his little book, "The Miniature Fruit Garden," and have

lately taken up all my trees, *Roses* and *Pears*, to replant them with dung. My gardener and I were both surprised to find such a mass of long fibrous roots, grown in one year, with the refuse hanging to them. I must observe that the refuse mulching was allowed to remain throughout the summer, and by watering it occasionally the ground was preserved from being parched and hardened.

I am just going to prepare an *Asparagus*-bed, and have directed my gardener to work in a quantity of the old refuse very freely with the soil and dung, and to sprinkle in a little salt. I shall have this turned over and well mixed at least twice before putting in the plants in March. This will make the soil rich and light, through which the *Asparagus* will shoot up strong and straight, as I have seen in the gardens of a gentleman who seems to have a mania for this refuse.—H. E., *Surbiton*.

### BURY HILL,

THE SEAT OF A. K. BARCLAY, ESQ.

IN travelling from London by the South-Eastern Railway, after leaving that labyrinth of lines which unite at London Bridge, the first few miles present the usual features offered by the suburbs of a large town. There seems, indeed, to be vast quantities of waste ground by the sides of the railway, more so than near most lines in less densely populated districts; but there is nothing to call for particular remark until the cold, bleak station of Redhill is gained—cold and bleak in winter, but pleasant in the extreme in summer—the new and rising town of Redhill appearing in full view, with its villas, and comfortable-looking dwellings clustered together in the valley, as well as crowning the various eminences by which the town is surrounded. Here the Dover and Canterbury lines turn off to the left, while the Brighton one proceeds straight on; but a branch of the South-Eastern curves round to the right, cutting through amongst the hills and deep valleys of Surrey, and it is a short journey on this line that brings us to Bury Hill. The scenery on the road thither is as much diversified as on any short railway journey I know. The deep cuttings and some high embankments give tokens of the vast quantities of sand which have rendered the name of Reigate one of our household words. A gardener travelling that way for the first time will see that there is no fear of fine white silver sand for propagating purposes ever becoming scarce, though he may envy the wasteful manner in which he sees it lying about. He may, however, console himself by reflecting on the fact that the overlying mould is neither plentiful nor of the best kind for cultural purposes. Some smiling vallies are passed through, the village of Betchworth is reached, and, leaving that, the eye instinctively rests upon the high chalk hill to the right, which is Box Hill, a favourite resort for picnic and other pleasure parties, and the traveller may remember being told that the Box tree grows wild here. Most of the boxwood required for various purposes was once supposed to have been obtained from this place; but large quantities are now imported from abroad, so much so as to cause fears of the supply being exhausted even in countries where the tree is more plentiful than in England. Box Hill, however, has, no doubt, contributed its share, and even now the plant is said to be plentifully spread over the waste, and with Yew, Juniper, and some Hazel and Birch trees, gives the top and abrupt sides of the hill a clothed appearance, which is rendered the more conspicuous by the white, chalky character of the surrounding ground.

Passing Box Hill, a short stage brings the traveller to the important town of Dorking, nestled as it were in a valley, the hilly district by which it is surrounded having more the stamp of distinct ridges than broken mountain scenery. Here we leave the rail, and a pleasant walk of about two miles brings us to the entrance gates to Bury Hill. A broad carriage road leads from the gates, curving right and left to meet the requirements of the ascending ground, and every now and then opening up fresh views, or, perhaps, a noble specimen of a tree planted by some former possessor arrests the eye. The curves and gradients are of that easy kind which modern roadmaking can find but little to improve upon. After traversing some distance thus prettily rather than densely clothed eminence, another turn of the road

brings us in view of the mansion, which resembles one of those commodious structures erected in the end of the seventeenth or beginning of the eighteenth century; when the comfortable dwelling-house was beginning to take the place of the feudal stronghold of earlier times. The principal front is to the south, but the carriage approach is on the other side, and on account of the inequality of the ground, the entrance is one storey higher on that side than the ground is on the south; but even this inequality is nothing compared with the rise in the ground at the north side, for after allowing sufficient space for the requirements of a carriage entrance, a grass lawn in one unbroken slope rises, I should think, not less than 100 feet. This beautiful and uniform slope is about 250 feet wide at bottom, but narrowed-in at top; and even beyond what might be called the top of this slope, another slope about 20 feet wide, still ascending, and at right angles with the front door, carries on the view to the top of the hill, on which an ornamental summer-house, or rather exploratory, for I believe it has been used for astronomical purposes, forms a suitable apex to an eminence commanding an extensive range of country. I may mention that the lower part of this fine slope is all of plain turf, and seemed to be somewhat steeper than the usual gradient adopted of late years—*i. e.*, two to one, or a base of 2 feet to 1 foot in perpendicular height. The slope was certainly steeper than this, say five to three, and if the perpendicular was 100 feet, we have a surface slope of about 200 feet, which had an imposing effect. The margins of this slope were planted with St. John's Wort, which here grows admirably, while the opening through the wood, continuing the view to the summer-house alluded to, was faced with Rhododendrons, which here also found a home such as evidently suited their wants in every respect, excepting, perhaps, that more water would have been grateful during the past season.

As from the description of the high ground at the carriage side of the house, it might be inferred that the mansion stands on low ground, I must conduct the reader to the south side, and there he will see that in addition to the difference of the height of a storey in the ground level, the latter still continues to recede for a distance of 100 yards or more; we then come to a beautiful piece of water, fresh, clear, and sparkling, twenty acres or more in extent, which occupies a position in the valley. There is a well-wooded island in it, and the outline is at suitable places concealed by planting and at others shown, so as to give a natural appearance to a sheet of water, which in such a situation can hardly be too highly valued. A lawn with a few specimen trees sparingly introduced, so as not to impede the view, connects the mansion with the ornamental water. The dressed ground is for the most part on the opposite, or rather the eastern side of the mansion, but there are many interesting walks and corners carved out of the wooded hill, against which the whole reposes.

Passing the mansion on the north side, and proceeding eastward through a shrubbery, we come to the principal flower garden, which, to protect it from rabbits, is fenced in with close wirework, but excepting at the gates, by which the visitor enters, and one or two other places, the fence is everywhere concealed by shrubs skilfully arranged. The outline of this enclosure is somewhat circular, and two walks cross it in the centre, leading or pointing to important features in the ground. A basin occupies the centre, around which are arranged a series of flower-beds, these at the time of my visit being well filled with Geraniums, Lobelias, Petunias, Verbenas, and other bedding plants. These beds were all on the turf, and outside were some specimen shrubs, and behind these again the best kinds of Pinus. The entrances to this garden, four in number, were planted with dense masses of Azaleas, which by their healthy appearance must have presented a most gorgeous appearance when in flower. As it was, in September, the foliage had the rich crimson hue which this shrub puts on late in the season. Some hybrid Rhododendrons were also in adjoining compartments, while the deep dense green of a noble specimen of Abies Douglasii, bearing cones, was matched in another place by a good Pinus insignis, planted in 1840. The height of these trees I omitted to ascertain, but they were of fair timber proportions, and to all appearance were likely to attain a great size.

As an accompaniment to the flower garden alluded to, was a rustic summer-house, thatched with the refuse shavings obtained in making wooden barrel hoops. The sides of this structure were also of a corresponding rustic character, and were partially clothed with Jasmine, and a good variety of Silver-blotched Ivy. Some rockwork which I was told was the work of the young ladies, adjoined, the whole being overshadowed by some noble Oaks. From this point walks curved in various directions, several of them ascending the hill, which, as previously stated, was clothed with valuable timber, which had been judiciously thinned, and Rhododendrons, Laurels, Berberries, and the like, planted by the thousand many years ago. These, of course, gave all the cover that the most ardent sportsman could wish, at the same time large open spaces had been cleared here and there, and specimen Pines of various kinds planted. Generally speaking, these specimens were in groups, some having been planted twenty years and more, and others of more recent introduction at a later period. All, or nearly all, were named, a sort of brick being used on which the name of the specimen, its native country, and the date of planting, were imprinted on the sloping end before it was burnt, and, of course, capable of enduring as long as the brick itself. I was told that the maker was a Mr. Locker, of Kingston, and certainly they deserved to be very generally used, for without being obtrusive, they were sufficiently prominent to be seen by all who might wish to know the names of the trees.

Among other Pinuses I noticed a fine specimen of Picea cephalonica, promising to rival the Silver Fir in magnitude, Pinus laricio, and Pinus insignis, which, though only planted in 1840, seemed to vie with the natural occupants of the forest. Cryptomeria japonica nana, on the other hand, forms a dwarf compact bush 3 feet high, and 4 feet through, more in the character of Thuja aurea, thus resembling the normal condition of the species of which there were also excellent representatives. Taxodium sempervirens, which is generally supposed to require a damp soil, was here in excellent health in one of the driest spots in the kingdom. I am sorry I cannot say the same of Araucaria Cunninghami, which, though doing as well as at any place where I have met with it out of doors, is evidently not sufficiently hardy to endure the climate of this country if left unprotected. Picea Webbiana, which does not thrive very well in most places, was better here than in many, and I was told that it perfected its seed. Some Cedars of Lebanon of much greater age were less promising than most things around them; but a fine specimen of Pinus cembra promised after a time to overtake some magnificent Silver Firs in close proximity. Picea nobilis and P. Nordmanniana were also well represented, the former taking the fine, conical, upright growth which renders it so great a favourite when it is well grown; the latter not so far advanced. Bushes of Thuja aurea were also to be met with in many places, where also a dwarf form of Abies, called A. Gregoriana, presented a dense deep green hue; while a still more dwarf or rather prostrate plant was Juniperus squamata. Ever and anon healthy thriving plants of Wellingtonia were to be met with in various stages of growth, and what must not be forgotten, some fine specimens of Deodar gracefully making their way upwards, while their bases had every appearance of the trunk being hidden from view for many years, so healthy, dense, and vigorous were they. I do not remember if there was a good specimen of Picea pinsapo, but believe there was, and most, if not all, of the lately-introduced species of Cupressus, Thuja, &c., were to be met with; but I did not notice all in detail. With one or two exceptions the whole were in excellent order, and the most of them were in positions which would enable them to grow on for many years without coming in contact with each other—a very common fault in many places where some of the finest specimens are to be found.

I have stated that the general features of the place are a steep hillside cut into ravines or gullies in various ways, the soil being sandy, and, doubtless, containing iron in more or less abundance, as the Rhododendrons succeeded so well, and ripened their seed and reproduced themselves in the common wood. A long period of very dry weather prior to the middle of September, when I was there, had told severely on the Kalmias and Andromedas, which were suffering much,

and one or two plants of Rhododendron were pointed out that had absolutely died from the drought; but in general all was luxuriance and health.

The good keeping of the place reflected the greatest credit on Mr. Whitehead, the gardener, to whose courtesy I am also indebted for the information above; and before leaving I must accompany him to the kitchen garden, which lies in the valley to the north of the mansion. Good high walls surround it, and some useful Grape-houses occupy the north wall. Peaches and Nectarines had been in great abundance on the walls. Strange to say, some fruit were growing in a glass case facing the south which were later than the same kinds on the open wall. The glass case consisted of tall sashes reared against the wall, the bottom being about 4 feet from it, and the trees were trained against the glass rather than against the wall, and, consequently, exposed to the back draught, which had neutralised all the advantages of the glass. The fruit here, as well as on the walls, was good; but the latter was said to be the better flavoured. Mr. Whitehead had also been very successful in Mushrooms, and in fact the general condition of every crop was good, considering that a very dry period had been passed through. Unfortunately my visit to this department was a hurried one, but I saw sufficient to convince me that Mr. Whitehead had not accomplished all that was done without difficulties, and that these had been successfully overcome; while the liberal manner in which the choicest Pinuses had been planted about, and the general formation of the grounds reflected the highest honour on his employer, who, I hope, may long occupy Bury Hill, which, with its noble sheet of water, its slopes, its secluded and romantic walks, its varied and interesting views, as well as choice plants and good keeping, has a claim to attention which few places possess.—J. ROBSON.

### WATERING NIGHT.

"A little water is a dangerous thing;  
Give much, or none, from the Alectean spring."

—OLD PARODY.

I SUPPOSE that every one who has lived in a country village knows something about "watering night" in summer time. Simpkins had for many years been a curate. Visitation after visitation Mr. Simpkins had been called over as "curate of the same." At last the bishop, at the instance of the archdeacon and some of the superior clergy, as well-to-do rectors are called, gave him a living—not a very fat one, but still it was an advance on the curacy, and enabled the Simpkinses to take up gardening in a modest way. They began floriculture with two dozen standard Roses. There was besides a little lean-to greenhouse, in which, alas! there was very little "green."

Let us take an "inventory," as Tom Tix expresses it in "Nicholas Nickleby," when reviewing Madame Mantalini's goods under an order from the sheriff.

Here is the old Black Hamburgh somewhat bigger than Elder berries; here are pot-bound Pelargoniums (Geranium is a better word, it is more like the Greek for crane's-bill); here is in fact a burnt-up specimen of "something, everything, and nothing."

It is watering night both under glass and outside of it. Robin, who had lived with them when S. was curate, now advanced to head gardener at 12s. per week and house rent free (expected to wait at table, though, party nights), is summoned. "Robin, have you forgotten it is watering night? Tell Eliza to bring down my coalscuttle bonnet with gipsy frill, and do you fetch my watering-pot (aside, about the size of two teapots), with long snipe spout. I am going to copy, as Mr. Radclyffe has advised us, 'a thunderstorm.'"

Robin had not forgotten "watering night." No night did he dread so much as "thunderstorm" night, and so answers somewhat surlily, "Oh, yes, ma'am, let us copy a wonderstorm." He had nearly got out the words "and forked lightning," when a look assured him that if he attempted to be pert she would tell his master and have him discharged.

"Now fetch a bucket of water, and don't be disagreeable." The water fetched, the pot with snipe spout is filled, and down comes the "thunderstorm." "There Robin, I think I have done it now."

"Oh, yes, ma'am, if the Giant and Baronne don't bloom now I'm a Dutchman."

"Now Robin, don't use offensive similes; I caution you once more. Fetch another bucket of water; let's begin *de novo*."

"Oh, yes, ma'am, as you say, let's begin again *de Jovo*."

"Robin, don't you see dear S. looking out of the 'studio' window? I have only just to hold up my little finger and he will come: length of servitude won't serve you. Come, be good-tempered, Robin. *Bonos mores* makes a man, or as dear S. says when he hears my voice, '—*emollit mores, nec sinit esse ferus*.' Come, fetch another bucket and Parkes's fork, and, as Mr. Radclyffe advises in his learned articles, let us 'touch all the points of the roots.'"

At this Robin chuckles with delight. He is always spiteful thunderstorm nights, and is glad of an opportunity of doing as much mischief as possible. Accordingly he tumbles the baked ground, and breaks off as many roots as he can.

Now, if Mrs. S. had stooped down and examined this tumbled ground she would have discovered that her thunderstorm had not penetrated the depth of a sheet of Bath vellum, and that Robin had effectually touched the points of all the roots with Parkes's fork. She has, however, had enough of it for this night, and exclaims, "Well, I never! It's teatime, dear S. is beckoning. There, Robin, I forget and forgive. Go in and get a pint of beer, and don't try my patience another time."

Robin cheers up a little, but he does not like watering night; and in a few days he has his revenge, and runs in with smothered delight to say that the Giant and Baronne are both dead, and that there is nothing like touching all the points of the roots with Parkes's fork and missus's thunderstorm.

In fine, whether a plant be in a pot or in the open ground, it is useless watering unless sufficient water penetrates to touch all the points of the roots. A little moving of the ground the day after with Parkes's fork will be serviceable, but beware of touching all the points of the roots.—W. F. RADCLYFFE, *Rushton*.

### WINTERING BEDDING PLANTS.

FOR the last two winters I have preserved my bedding plants in ordinary Cucumber-frames, by placing a small petroleum lamp in the centre of the frame, with a square piece of tin, above the flame, nailed to the frame. The lamps, which cost 1s. or 1s. 6d., are sold by all ironmongers. The spirit costs 3s. per gallon, and the consumption is not great, as the wicks are small. I adopt the additional precaution of surrounding my frame with straw about a foot thick; the glass is also covered at night with straw mats.—G. C., *Chadlington*.

### FRENCH VERSUS ENGLISH ASPARAGUS CULTURE.

MR. WATSON, at page 510, finds fault with me for giving my opinion on the French system of growing Asparagus as applied to the climate of England. I can only restate my conviction, after growing Asparagus on both systems—English and French—that "there is no benefit in the French system," for we do not measure the value of Asparagus in England solely by its appearance, but according to its utility.

Growing Asparagus with a blanched shoot is no new practice even in England, and it is one not likely to take with the English, though it may be in request at aldermanic dinners. I have eaten French Asparagus, and though it be a little more tender than that of English growth, after discussing about 3 inches of the tips the lower part reminds me of what I used to find a stick of liquorice in my youth, exceedingly woody.

As to my thinking nothing can be good out of England, I know, however much some people can see in other countries, that England, and especially her gardeners, are looked upon as patterns of that which is good. It has been said that we should never be able to raise as good Roses here as in France, but John Hopper, King's Acre, and

other results of English efforts, prove that in our ill-adapted climate we can equal even the French in Rose-growing. We have done what other nations said we never could, and L'Hérault's assertion that "we shall never grow as fine Asparagus in England as they do in France," may be classed as one of those impossibilities. We have grown as fine Asparagus in England as was ever grown in France, if that named by Mr. Watson be the heaviest grown there, and Englishmen can grow fine Asparagus without worn-out vineyards.—G. A.

#### ROSES IN THE NORTH OF IRELAND.

I FULLY agree with the remarks of your-reverend correspondent in your Number of December 20th regarding Roses on the Manetti stock. The result of my observations and practice leads me to fully corroborate your correspondent's article. I found Roses generally do far better and bloom more profusely on the Manetti stock than the Briar. Roses budded on the Dog Rose were very subject to moss on the stocks, the result being a sickly plant and premature death: whereas Roses worked low on the Manetti escaped, and grew luxuriantly. As regards kinds adapted for the north of Ireland, all kinds which thrive well in the midland counties of England would, I think, do well, even in the north of Ireland. The winters are not there so severe and fatal to Roses as in some parts of England. When such things as *Linum flayum* will stand out of doors unscathed, I think the generality of the Rose tribe will not be injured. I can only say that while I was in Ireland I never met with a death resulting from frost.—JOHN EDLINGTON, *Wrotham Park, Barnet.*

#### MANAGEMENT OF FLOWER SHOWS.

IN the locality from which I write we have had for the last six years a very successful flower show, but I am afraid its days will be short if some alterations are not made in the rules and committee of management.

In the first place, exhibitors are allowed to purchase any plant eight weeks previous to the exhibitions. This is quite long enough, and where a collection may casually happen to lose a plant it is quite right that a short time should be allowed to fill its place up. This I do not complain of; but when a person purchases an entire collection to compete for the prize just eight weeks before the show, thus preventing or taking the place of one who has grown his plants from mere cuttings, and has cultivated them as many years as his more wealthy neighbour has done weeks, this seems to me unfair. By such a proceeding many old and first-class cultivators will cease to exhibit against a rich man, and I, for one, think very properly so too.

In the second place, there is a committee of about twenty in number, and two of them are the most determined of the prizetakers. The remainder of the committee care not who get the prizes, all they desire is a good exhibition and large company. In such a case it will not be difficult to demonstrate that the power of these two exhibitors predominates in the committee, and the unequal schedule of prizes will clearly show that its compilers are interested in competing for the prizes.

Another, and by far the greatest mismanagement, is in the choice of judges. Complaints against their decisions are numerous. Two judges are chosen in each department, with a referee in cases of collections being in their opinion of equal merit. This referee ought, as well as the judges, to be, as far as can be, a stranger, and more so to the plants; but I have too often heard that they only decide in favour of those collections with which they are acquainted when two are so equal that it is difficult to say which is the better; which difficulty often occurs. Under such judges the stranger has but a poor chance of winning many first prizes. Are there no means of leaving the selection of the judges to the exhibitors? How are they selected at the great London shows? At all events, let the names of the judges be known, and then exhibitors may use their own discretion as to placing their productions before them.

I am also of opinion that it is much better that all these horticultural shows should be managed without the exhibitors

being on the committee. I shall feel greatly obliged by a small space for these notes in your columns, in order to elicit the opinions of some of your correspondents, as they may be of great service to the managers of many provincial shows, which is my object in writing.—R. F., *Thirsk, Yorkshire.*

#### DRESSING THE STEMS OF ROSE TREES.

I AM purposing to scour the stems of my standard Roses with Gishurst compound, in the course of next month (January), in the same way that I have found so beneficial to the stems of fruit trees. Would you recommend half a pound of the compound dissolved in a gallon of water as about the right strength? I suppose it would be all the more efficient if applied warm—say at a temperature of 100°. Should I be in danger of doing mischief if I were to syringe the heads of the trees at the same time with the same solution? The scrubbing, I conclude, should be done in the absence of frost. I suppose any temperature above 36° would be suitable.—COUNTRY CURATE.

[Perform the operation in mild weather, and treat the tops, with a brush or syringe, with the mixture not so strong as for the stems.]

#### POTATO PRODUCE.

"AGRICOLA" having doubted the results of the experiments of "W. W. H., *Prescot, Lancashire,*" with Paterson's Blue Potato, I am induced to offer a few remarks on the growth of this root.

First, I beg to notice that in neither of the communications of "W. W. H.," nor of "AGRICOLA," and "UPWARDS AND ONWARDS," is mention made of the distance apart at which the sets were planted. "AGRICOLA," however, calculates the produce per acre, according to the produce obtained by "W. W. H.," from 14 lbs. of sets, to be upwards of 50 tons per acre. "The quantity of seed for an acre at the ordinary distance," continues "AGRICOLA," "with rows 3 feet apart, &c." Now, what the ordinary distance may be is the question of which we are left in total ignorance, and this is one of the greatest points in computing the produce per acre, for it does not follow that sets 1 foot 6 inches apart will yield as much per acre as those at 2 feet apart, or at 3 feet apart. Nor do any of them give the weight of the sets. These might weigh 4 ozs. (a large set), or 2 ozs. each, and the ground being planted with the larger size in rows 3 feet apart, and 18 inches asunder, 9680 sets would be required to plant an acre, and there being 56 sets in a stone, each weighing 4 ozs., the return per acre would, at forty-four times the weight of the sets, be a little over 47½ tons; but were the sets only 2 ozs. each, the produce per acre would be only 23½ tons.

Experiments of this kind are apt to lead to an incorrect conclusion when the produce per acre is calculated by the produce of a certain weight of sets without stating the extent of ground occupied by them. We do not want to know what kind of Potato gives the greatest yield from the least seed, but the Potato that affords the heaviest crop from the least extent of ground. We want to make two blades of grass grow where one only grew formerly. Potatoes affording a large return per root require a large amount of room for their shrub-like haulm, whilst those with smaller haulm can be grown in one-half, or a proportionately less space, so that with two kinds the results may be very different, and this through planting at improper distances. Suppose we plant the Scotch Regent in rows 2 feet apart, and only 1 foot from set to set in the row, the return would not equal that of the Ash-leaf Kidney, for the distance would suit the latter, but be insufficient for the requirements of the former; yet plant the Scotch Regents in rows 3 feet apart, with the sets from 18 inches to 2 feet apart, and they would give nearly double the produce of the Ash-leaf Kidney though planted at a much greater distance.

Incredible as the return of Paterson's Blue Potato, as given by "W. W. H.," may seem to "AGRICOLA," I may state that for 14 lbs. of sets to yield 618 lbs. of tubers, is not at all extraordinary. There being 56 4 ozs. sets in 14 lbs., the yield per root is only 11 lbs., no great weight that, it

being 5 lbs. less than a root of Negro grown this year by "UPWARDS AND ONWARDS," and noted at page 466.

Great as these weights may seem, I have communications from different parts of the kingdom, which show that the weights named by "W. W. H.," and "UPWARDS AND ONWARDS," are comparatively poor. One of these instances of extraordinary produce I copy, with the name of the grower, the gentleman in whose garden the two roots were grown, and the particulars of their cultivation.

The note is from a worthy representative of gardening, and the return so far eclipses any I have of the growth of this root, as to appear incredible; but it will best tell its own tale.

"December 12th, 1864.

"I must tell you about my Potatoes. I planted on the 24th of March two sets of the Scotch Regent Potatoes, 4 feet distant each way, and 2½ inches deep. The ground was dug 24 inches deep twelve months previously, and well manured. When the shoots were 6 inches high they were soiled, and the stems brought down or laid out—that is, spread out, soil being laid in the centre as they grew, and the haulm pegged down, until they all became one mass of foliage. They were watered with liquid manure, soot, rape dust, and salt when they required it, about once in six or nine days. They were taken up on the 2nd of November, and the produce was—No. 1, 43 lbs., number of Potatoes 101, six weighed 11 lbs. 3 ozs., one Potato out of the six weighed 2 lbs. 9 ozs.; No. 2, 41 lbs., number of Potatoes 98.

"My master was challenged by another gentleman to grow Potatoes for a wager of £1, and that was the cause of my trying my hand at the feat to be accomplished. The gentleman came to see the Potatoes taken up, and he said if he had not seen this done he could not have believed such an enormous quantity could be grown. He has been experimenting on Potatoes for several years, and thought no one could beat him. The heaviest root he ever grew was 20 lbs. He never told us the weight of his, but owned he had lost his sovereign.—FRANCIS LUPTON, Gardener to S. Grimstone, Esq., Cliford, Tadcaster, Yorks."

In the foregoing we have a return of 100 times the quantity set in number, and of 168 times according to weight; but this produce, prodigious as it is, is only some 51 tons per acre, or 3½ tons more than the weight obtained by "W. W. H.," though the sets produced nearly four times the weight per root. This is, of course, owing to the distance apart being greater.

The above is the heaviest crop of Potatoes as yet grown. I may state in conclusion, that 200 tubs of 20 stone are considered a good crop for an acre of warp land, such as that near the Ouse, in Yorkshire; but I have a note of 400 tubs having been taken up from an acre of such land, which at 20 stone per tub is 50 tons. From 200 to 250 tubs is the average of the produce of an acre of York Regents, and taking the mean of twenty of the highest returns the figures are 223 tubs, or a little over 27 tons. The average of fifty acres from as many different growers is, taking a fair season, 52 tubs, or 6½ tons, under ordinary farming worth £20, sold as grown, but such land is not well suited to the Potato.

Would it be troubling "W. W. H.," or others of your correspondents to inform me if they find Paterson's Blue distinguishable from Skerry Blue, or Paterson's Regent from the Scotch Regent? Notwithstanding the introduction of many new sorts there is none surpassing the Ash-leaf as an early, the Lapstone as a second early, and the Pink-eye for table, and to them may be added the Fluke, though it is not anything extra in flavour, and it is almost always yellow. Arrowsmith's Seedling is, I find, an excellent Potato after the Pink-eye, but it is only a poor cropper. Almost invariably the largest croppers are the coarsest Potatoes, and have deep eyes, which is a distinguishing sign of a cattle Potato.—G. ABBEY.

#### WHAT IS A BUSHEL OF POTATOES?

I AM very glad to find that "W. W. H.," in writing of Potatoes at page 472, describes the quantity grown by weight; for measures are subject to so many local customs, that the term "bushel" carries with it a very indefinite meaning, although perhaps not so much so as a yard of butter in the

eastern counties, or a gallon of bread in Kent. Still, a bushel of Potatoes does not always imply the same quantity in all places. In some the old local measure is used for Potatoes, although the imperial one is employed for corn, and the difference in certain cases is very great indeed. The plan, however, of giving the weight is certainly preferable even to the imperial measure, as so much diversity of opinion exists as to what ought to constitute a heaped bushel. Some contend, unreasonably enough, that the buyer has a right to pile the Potatoes on the measure by hand, thereby giving a dexterous person the advantage of putting on almost as many as he likes; others affirm that Potatoes may be poured out of a sack or basket into a bushel, and all which lie on without any handling constitute the quantity sold; while in many districts the custom is to disregard the measure entirely in the way of using it, but to consider a certain weight to constitute a bushel, generally, I believe, 56 lbs. This plan is certainly preferable to the measure; but in adopting it the term "bushel" might as well be dropped, and the article sold by weight at once. "W. W. H.'s" plan of giving the weight of the seed and crop is certainly a step in the right direction, and I trust other writers will adopt it, as the pound avoirdupois is, I believe, the same all over England; but a load of hay, an acre of land, a gallon of bread, or a bushel of Potatoes often enough differ widely in the quantities they imply, and the sooner local terms are dropped the better, especially when recording experiments or other matters intended for general information. Weight seems a much fairer way of describing quantity than measure. I am glad to see that in some of the Lancashire markets fruit and other things are sold entirely in that manner. The justice of this mode of buying and selling will no doubt cause its adoption in other districts, even in spite of long-established customs, prejudices, and perhaps some other motives less justifiable.—H. L.

#### WORK FOR THE WEEK.

##### KITCHEN GARDEN.

ALL trenching, rough digging, gravelling walks, &c., ought to be pushed on as fast as possible. Now is also a good time to keep burning and charring all the prunings of trees and shrubs, rubbish, sawdust, &c.; where ground has been trenched and well manured with dung, charred earth and wood in good doses have a wonderful effect in restoring fertility and keeping grubs and slugs in check. *Asparagus*, if the soil in the bed should become dry give them a liberal supply of water, so that it may reach the roots. *Carrots*, where young ones are wanted early prepare a slight hotbed for the purpose, cover it with leaf mould to the depth of 6 or 8 inches, in which sow the seed. A little Radish seed may be scattered on the bed at the same time, but they must be drawn in a young state. *Lettuce*, where there is a scarcity of autumn-sown sow on a slight hotbed, or in boxes in a forcing-house, to be afterwards pricked-out into a frame. Fill up all vacancies in Cabbage and Colewort-beds with plants kept back for that purpose in the autumn, and keep the surface about them constantly hoed and stirred with a fork. Endeavour to keep well up with all work in this department, the time is fast approaching when you will find the advantage of having done so.

##### FRUIT GARDEN.

Continue the operations of pruning and nailing the hardier kinds of fruit trees at every available opportunity. Have a plank to stand upon, and if very cold, wear also a large pair of wooden clogs. No considerate employer will ever censure a man for being careful of his health. Where birds are very numerous the pruning of Gooseberries may be deferred for a time, as if sharp weather prevails during this and part of the following month, they are apt to be very destructive to the buds. Prune espalier Apples and Pears, and fork up the ground about them in frosty weather to disturb and destroy insects. In the orchard thin out cross and crowded branches from Apples, Pears, and Quinces. It is a great mistake to have too much wood. Scrape off moss and lichen from the stems, and, if time will permit, dress both these and espaliers with a mixture of quicklime and clay, made to the consistence of thick paint. If this is done well there will be no need to scrape them for some years.

## FLOWER GARDEN.

The planting of shrubs and choice trees may still be carried on. These operations should be prosecuted vigorously as long as open weather lasts, and brought to a close as speedily as possible. Dahlia roots should be occasionally examined, in order to counteract the effects of damp. If unfavourable weather should occur much incidental work relating to the flower garden may be forwarded, such as the preparation of nails, shreds, and ties for training climbing plants, stakes for supporting the stems of such as require them, labels of all kinds and sizes, the construction of covers for protecting purposes, repairing rustic baskets and tubs, mixing composts, cleaning pots, and the breaking up and preparation of materials for the drainage of pot plants.

## GREENHOUSE AND CONSERVATORY.

As severe weather may now at any time be expected, a good supply of dry litter, fern, or other such materials, should be in readiness for extra covering when required. If not already done, lose no time in getting under cover a supply of the various loams, peat, &c., required for spring potting. Keep the conservatory at a temperature of about 45° by night, raising it to 55° in the day, with plenty of air at every favourable opportunity, and the house may have 60° or 65° by sun heat without injury. Keep the atmosphere moderately moist, as much for the preservation of the flowers as for the comfort of the visitors. Stove plants will take no injury for a few days in this temperature; but hard-wooded plants, such as Heaths, should not remain more than a few days at a time in such a temperature. The greenhouse in the generality of places is a mixed affair where hard-wooded and soft-wooded plants are obliged to be together. In such places a compromise must be made in the treatment by keeping the air a few degrees warmer than Heaths and other Cape plants require, and yet sufficiently warm for Pelargoniums, herbaceous Calceolarias, &c. Arrange the plants in groups, so that air may be admitted to the Heaths at times when it would be injudicious to admit it to soft-wooded plants. Camellias will now be swelling their buds, neglect in supplying water must be avoided, and attention should be given so that it is applied in proportion to the activity of the growth of the plants.

## STOVE.

The season is not yet advanced sufficiently to allow an increase of temperature. A steady heat, ranging between 60° and 65° may be sustained, if the weather continues open. The occurrence of frost will demand a reduction of temperature. Allow the thermometer to sink at night. Artificial heat without light, as has often been explained, is injurious to vegetation. Recollect always, that stove plants, as well as others, require fresh air. The stove may still be gay with the beautiful *Genera zebрина*, *Euphorbias*, *Begonias*, &c. Some few Orchids will now be in active growth. These must be supplied with moisture as opportunities allow. Keep *Ixoras* close to the glass and at the cool end of the house.

## FORCING-PIT.

Remove the plants from here to the conservatory as fast as the flowers expand, and introduce others from the reserve for succession, placing them first at the cool end of the pit so as to excite them gradually. A few Pinks and Sweet Williams may be started, and plenty of Lily of the Valley, Sweet Briar, &c. Gardenias must also be started, and as *Stephanotis* is a great favourite with the ladies, a plant or two should be placed at the warmest end of the pit. Maintain a fresh, growing, moist temperature of from 60° to 65°, or 70° with sun heat, and give air, warmed before it gets to the plants, at every favourable opportunity. Syringe early on sunny days, and keep a moist atmosphere, unless the weather is very dull.

## PITS AND FRAMES.

As long as the temperature here can be kept from 32° to 35° little harm will ensue by keeping them covered. It is a good practice to tilt the back and front alternately whenever the glass rises above 32° out of doors. By these means the accumulating damp is dispelled, and the plants receive as much light as will prevent etiolation. Take care that the roof is well protected, using a mat near the glass and then a coat of dry litter, the thickness of the coat to depend upon the state of the weather.—W. KEANE.

## DOINGS OF THE LAST WEEK.

*Ice-collecting.*—Keeping Monday as a holiday, we set to work on the Tuesday and Wednesday to collect what ice we could, but had to be content with less than the usual quantity, owing to the scarcity of water as yet in this neighbourhood. The ice was in capital order, 1½ inch in thickness, and the roads, clean and dry, made the job a comfortable one for men and horses. A heavy fall of snow, or a good rain, would be of great benefit in this neighbourhood. Large ponds, that used to be full to overflowing at this season of the year, had scarcely enough in a small corner to meet the demands of the cattle; and taking what little ice there was, in such circumstances, was not to be thought of, the necessities rightly coming before the luxuries of existence. We feel we are now secure for at least one year and a half, and if we can collect a little more from a future frost, we will be pretty secure for two years. Our icewell is an old-fashioned egg-shaped one, with single wall, and a long passage. We think the ice goes a little more quickly than it used to do, owing to the cutting down of the Spruce and other trees which surrounded it, and to birds and rabbits scraping away the earth, and burrowing in the earth-covered arch. If we can get at it, we would like to put a cover of a foot of earth all over the dome, and plant with Laurels and other evergreens. A few Spruce Firs, just thin enough to enable their branches to cover the ground, would also be an advantage, and so would their habit of sending their roots along the surface, and thus keeping free of the brickwork. Trees that send their roots deep down would be unsuitable, as we have found even cement walls penetrated and cracked by such roots. We once saw a seemingly sound wall topped over by the roots of Oak and Elm loosening and throwing up the foundations. This was even less to be wondered at than noticing, in another case, heavy flagstones raised out of their place by a crop of Mushrooms. Some spawn must have been present in the soil used for levelling. The massive solidity of the stone had to give way before the vital forces of such an humble agency as a Mushroom.

*Holidays.*—Alluding to Monday as a holiday, shall we offend by saying a word on the subject? We will not advocate the importance of working men having a few of such holidays in the year, we will assume that is freely granted. We will also assume that the employers who generously give such days as Christmas and Good Friday, &c., and pay the usual wages, will lose nothing by such generosity. The man is hardly worth having who will not more than make up, by extra exertion and attention, for such proofs of kindness. To constrain a man to be idle on such days, and then mulct him of that which keeps the loaf in the cupboard for his little ones, will be about as effectual for imparting pleasure as forced prayers would be for securing a blessing. What we wish pointedly to allude to, is the desirability that such holidays as the 26th ultimo, should be general in a district. We saw numbers of farmers' carts and waggons loaded on the highway, and later in the afternoon than they are generally seen on other days. We believe that the thus keeping the horses and men employed proceeded not from any want of kindly feeling, but from something like a desire to show an independent singularity. We arrive at such a conclusion because when it so pleases such employers, and nobody else is thinking of such a thing, they will give their men a holiday, a dinner, a cricket match, &c. We must not conceal, however, our conviction, that such kindness is strongly seasoned by vanity, and the desire for notoriety. Such an unwonted holiday, however seldom given, will be the talk of the neighbourhood at the time, and most likely will be recorded in the columns of some local newspaper. All such notoriety would have been lost, if the holiday had been given at the same time with that of the generality of the neighbours. The fact that even the humblest labourer sees through the whole affair, may help to lessen the prevalence of this ambitious singularity. If not, then a regard for their own self-interest, as well as the interests of others, may have some force. The sullen, wearied, if not morose physiognomy of carters and waggons, told at once they felt somewhat aggrieved at being forced to labour when their neighbours were enjoying themselves with their friends. Such men would, no doubt, do their day's work then and afterwards;

but it would merely be a day's work, a very different thing from the labour prompted by cheerfulness, and a sense of kindness conferred. We have no hesitation in saying, that before the week was out, the value of the Monday's work was more than gone. Then, it is not only themselves such sticklers for singularity hurt, their one own prominent holiday becomes prejudicial to their neighbours. It matters not, though these neighbours may give double or quadruple the indulgence that they do, when their one great holiday of their own choosing comes; with its due amount of trumpeting for fame, the less or greater will be the unsettlement of the workmen in the neighbourhood. They may have three or four holidays instead of this one so trumpeted; but this is all apt to be forgotten whilst the vision of others enjoying themselves, whilst they are working, is ever present to their minds, and with what results, every superintendent of labour that is paid by daily wages, pretty well knows. The abettors of singularity, then, even if they choose to forget the strong feelings for social intercourse, which prompt people when they rejoice, to rejoice in company, may be so influenced by their own self-interest, as well as the interest of their neighbours, as to promote, instead of prevent, the general observance of our national holiday, unless when interfered with by the claims of necessity and mercy.

*Protection.*—The details as to the kitchen and fruit garden would merely be a repetition of previous weeks. As respects everything tender in vegetables, fruit, and flowers, we never had an easier Christmas. The frost was so mild that little covering was given where artificial heat could be applied; and yet it was severe enough, and the days dark enough, to warrant us having all our cold pits and frames, where plants and vegetables were kept, shut up and covered up from Friday, the 23rd, to Thursday, the 29th, when everything was uncovered, as the frost was gone. As stated the other week, provided such shut-up plants are cool enough not to grow, it matters little at this season whether the darkness of their night should be sixteen hours, or sixteen times twenty-four hours in duration. If the heat enclosed is sufficient to cause the plants to elongate and grow, the results would be different; where heat is applied light must also be given.

#### SUNK PITS OR HOUSES.

Three correspondents have inquired if they may safely follow out the plan indicated by "ISLE OF WIGHT," at page 511. With every desire to be grateful for the good idea suggested, we must, we fear, answer decidedly in the negative. Mind, if the preservation of roots, fruits, and vegetables with a frost-proof roof were the objects, then we would subscribe to almost everything that "ISLE OF WIGHT" holds out. Were the sinking of walls as much as possible below the surface to secure these walls from the variations in our atmosphere, as respects heat and cold, then we so far agree, and thus accept the proposition that such houses and pits will require less heat than one with the walls exposed, and more especially if these sunk walls are insulated from the surrounding soil by enclosed air, or other non-conducting material: hence we find the importance of surrounding the high exposed walls of pits in winter with straw, neatly laid on. In our correspondent's sunk house or pit he would receive the above advantage less or more from the sunk walls, but then the glass roof, and the radiation of heat from it, would, ere long, in a cold night, make the bottom of this six-foot-deep pit as cold, nearly, as the outside atmosphere. This would, no doubt, be to a considerable extent neutralised by the stretched covering beneath the glass; and so it would be by a double glass roof, but these are equal preservatives in the case of pits partly or wholly raised above ground. Besides all this there are two objections against this deep sinking—the minor one, the diminution of light just at the season when, owing to the oblique rays of the sun, light is most valuable; and the greater objection would be the almost impossibility of keeping plants from damping in such a deep-sunk place, without means being taken for drainage, insulating the walls, and securing ventilation, that would be more troublesome and expensive than a pit built, protected, and heated in the usual way. Though we thus express our opinion plainly, we are not the less thankful for the ideas presented, so suggestive of improvements.

#### ORNAMENTAL DEPARTMENT.

Pits exposed at the sides were covered neatly by an inch

of wheaten straw tied on, which will make the entrance of frost there next to an impossibility. Calceolarias had a little litter thrown over the glass, and a few tree leaves thrown over all. There is no better protection from frost than these leaves, if at all fresh and dry, the drawback is, that they are apt to be blown about and make such a litter, and, therefore, we only use them on an emergency; but anything is better than letting the frost in. The disciples of neatness in the extreme, must use fire heat in some shape, or have ever so many thicknesses of mats or frigi domo, to keep John Frost at bay. As frequently stated, wooden covers, and a little straw or hay in very extreme cases, are the best of protections; but then many of us must make the best of what we can get, and visible utility does much to neutralise an ugly, rough appearance.

A slight, neat covering, even of frigi domo, or a mat, will be of much service in a cold night, even where fire heat is used, as less drying heat will thus be necessary—a matter of much moment in low houses and pits, where the amount of air enclosed is but limited. The reason why plants often flourish better in lofty, large houses, is just owing to the abundance of air all round them, and the greater slowness with which that air is changed in its properties and temperature. Hence though Geraniums will flourish well enough in a pit, with but a limited amount of air and light falling chiefly above them, it is rarely they do so well as in a loftier house on a stage, where air and light permeate all through, below, and around, as well as above them. Cold and heat tell also much more slowly and gradually on such houses.

The giving air, therefore, which must now be done with care in all houses, must be attended to with extra care in low houses and pits, just because they are so much easier heated and easier cooled. Half an hour's bright sun, that would do no harm in a large lofty house, but rather tend to give an active motion to the enclosed atmosphere, might be enough to injure very much the denizens of a small pit or frame. A little air, and early, at the highest point, will be the true safeguard; and, provided that is given early, to prevent accumulated moist heated air, the gradual rise of the temperature by sunlight will do little harm. With the above precaution, sun heat will scarcely be able to draw or weaken a plant. The time—the *early giving* of air—is of far more consequence than its quantity. In such sunny days as we have sometimes had lately, but the atmosphere cold behind the sun, an inch of air at the back of a frame, early, as soon as the sun began to tell on the glass, and adding a little more as the sun was at the meridian, reducing in the same way, and shutting up by two or three o'clock, would be far more agreeable to the plants than letting the house or pit alone, and then giving 6 inches or a foot by ten or eleven o'clock, thus giving the plants a vapour bath for one part of the day, and for the other part a dry, cold, scorching air, to help to mummy them into skeletons. One-half, or three parts, of the mishaps with so many of our amateur brethren proceed from the carelessness as respects early air-giving. Even city men would not need to give so many somewhat puzzling directions to Jane or Mary, as to their pit or little house, if they would only themselves give a little air at the top before they took their breakfast, and started for business by rail or omnibus. A gradual rising by sun heat after that, and as gradual a sinking to the point of safety, would be much better than the sudden changes effected by careless air-giving.

Even in dull muggy days a little air should thus be given, and, where fire heat can be afforded, that is better applied during the day than at night, allowing the heat to get low as the heat is taken away. Where a flue or pipe can be used, the safest plan, at this season, would be to keep always a mild heat in the heating medium. This would provide against a sudden frost at night, and, in a mild muggy day, would keep the atmosphere in motion, and allow of a little air being given without too much lowering the temperature.

In watering we have been careful to use as little as possible by spilling it on stages or paths. In cold pits it is best to take a dry plant out, water, and, when drained, replace it. In stoves, where a high temperature is given, moisture must be used for evaporation, to prevent the air getting too dry; and the keener the frost, and the stronger the fires, the greater the quantity of moisture needed, to

prevent the atmosphere becoming too arid. In houses at low temperatures, such as greenhouses and pits, from 40° to 45°, such moistening of the air will not be required, unless in severe frosts, indeed, when sprinkling the stages and paths slightly may be an advantage. In mild muggy weather, the escape of moisture from the pots, and the naturally moist state of the atmosphere, will render all artificial additions of moisture to the air unnecessary. A little fire heat, to make it drier, will oftener be required, and that will, too, give movement to the air, and thus benefit the plants. A little consideration will make all right.—E. F.

COVENT GARDEN MARKET.—DECEMBER 31.

In consequence of the holidays trade is not so brisk as it was before Christmas, and supplies continue ample for all requirements. Apples and Pears are still plentiful, but the best specimens of the latter for dessert purposes command a high figure. Grapes and Pines are quite sufficient for the demand. Of the former some excellent Black Hamburgs are to be had, as well as good bunches of Barbarossa. Greens of all kinds are abundant; Cornish Broccoli is now beginning to come in in quantity; and of Potatoes there are heavy arrivals both by the Great Northern and coastwise. Cut flowers chiefly consist of Orchids, Camellias, Azaleas, Pelargoniums, Roses, Heaths, Chinese Primulas, Poinsettia, Lily of the Valley, and Early Tulips.

TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

ACUBITIA DELTOIDEA (J. L.).—The Acubitias very much resemble the Arabises, the Arabis deltoidea being properly Acubitia deltoidea. Arabis purpurea is the same as Acubitia purpurea. The Acubitia deltoidea is the same as the little Hiac Arabis.

RESTING GESNERAS (M. H.).—Gesneras should be brought to a state of rest after blooming by withholding water and placing them in a drier atmosphere. The usual period of rest is the first four months of the year if they bloom late, as yours have done. The last edition of the "Cottage Gardeners' Dictionary" is the seventh, published by H. G. Bohn, York Street, Covent Garden.

COTTAGE GARDENERS' DICTIONARY (E. M.).—We have no interest in the work. It belongs to Mr. Bohn. No supplement has been published.

SYRINGING VINES (Sarum).—You are right in syringing the Vines, now breaking, every morning with water of the same temperature as that of the house. If the eyes of the young Vines are round and plump you may force them if they are in pots sufficiently large. If not already in pots 12 or 13 inches in diameter, pot them into such at once, and if you expect a crop of fruit next year do this without disturbing the ball. If not large enough to fruit another year pot them all the same, and cut down to two eyes; but if you fruit them they will not require pruning at the length they now are. You should have stated for what purpose they were grown, and then we could have been more explicit.

TRITONIA AUREA—SAFFRON CROCUS NOT BLOOMING (Idem).—Of course you will please yourself about the Tritonia aurea, and keep it secure from frost. It is an evergreen because you force it into growth. The most probable reason of your Saffron Crocuses not blooming is their having been taken up when they mostly flower, which would weaken the bulbs so much that they would not bloom in the following season. Had you planted them in spring instead of autumn it is more likely they would have bloomed in autumn. Once planted the roots should not be taken up in spring, but remain in the soil the whole season. They do not require any of the drying process.

HARDY FERNS FOR EXHIBITION (A Novice).—Lastrea Filix-mas cristata; Athyrium Filix-fœmina corymbiferum, A. Filix-fœmina depauperatum; Blechnum spicatum ramosum; Athyrium Filix-fœmina plumosum, A. Filix-fœmina apuiforme; Asplenium fontanum, A. trichomanes incisum, A. marinum ramosum; Struthiopteris germanica; Osmunda regalis; Polystichum angulare proliferum; Adiantum pedatum; Polypodium alpestre, P. vulgare cambricum; Lastrea Filix-mas depauperata; Scolopendrium vulgare, vars. subcornutum, multifidum, submarginatum, ramosum, endivia-folium; Polystichum angulare proliferum Wollastoni; Asplenium Halleri; and Adiantum capillus-Veneris Moritzianum. You may grow all the foregoing in a frame deep enough, shaded in summer, and protected in winter from severe frost. "The Taxidermist" gives directions for stuffing birds.

PROFITS OF A VINERY.—I, as well as several of my neighbours, would feel extremely obliged to your correspondent "S. Ryder" if he would detail a few particulars respecting his vinery—viz., as to the time of cutting his Grapes, price per pound, &c., as we find great difficulty in disposing of any garden produce at all, being nearly 100 miles from London. As to any profit we never dream of it.—H. H., Leicester.—[Although the house mentioned by me at p. 512 is heated, it is the same apparatus that was put in when an orchard-house was contemplated. There is no forcing used; the Vines are allowed to break naturally, there being no fire used except to keep out the winter and early spring frosts, on account of the plants. The first Grapes were cut August 26th, and exhibited at the Botanic Gardens, Manchester; but the cutting for sale commenced October 14th, and the last were cut December 2nd. They were sold chiefly to Mr. Copland, Victoria Market, Manchester.—S. RYDER.]

GRUBS (J. C. C., Saffron Walden).—The grubs sent are the larvae of a very common two-winged fly—Bibio Marci, or an allied species. They are generally supposed to feed on decaying vegetable matter, but would probably attack the roots of Fancies, &c. It would be well to dose the soil with lime water.—W.

JERUSALEM ARTICHOKE HARD (Frank M.).—We should think if planted in fresh ground and well manured, that they would produce tubers the reverse of hard. They should have an open situation. We can only account for the tubers being as "hard as stones" through their being grown in poor soil under the shade of trees, or through some defect in the cooking. We never heard of the like before.

RIGHT TO TAKE AWAY MANURE (A Constant Reader, Campbelltown).—You can take away the dung used for making hotbeds, unless there was an agreement with your landlord that all manure made on the premises is to be employed on the land, and unless the Melon and Cucumber plants are growing now on the dung, for an out-going tenant has no right to destroy a growing crop.

FOUNTAIN AT DINORBEN.—We are informed that we are mistaken in supposing the fountain at page 514, to be a representation of the one at Dinorben House, as it is only the upper 12 feet of it adapted for, and called, the small Hebe fountain. It was made for the Exhibition of 1862, price about £60, and one like it for Sir James Esq. Jeegebbay; but the grand Hebe fountain, as it is at Tunbridge Wells, cost about £280.

MISTLETOE ON TREES (Druidus).—We know of no place where you can purchase trees with Mistletoe growing on them. It may be propagated from seed, and the best months for sowing it are February and March. Make two cuts in the shape of the letter V on the under side of the branch of an Apple tree; make the cuts quite down to the wood of the branch, raise the tongue of bark made by the cuts, but not so as to break it, and put underneath one or two seeds freshly squeezed from the Mistletoe berry, let the tongue back, and the process is completed. If the seed is good, the seedlings, not unlike Cucumber plants, soon appear. They remain attached to the branch, and do not seem to injure the tree. Open the bark underneath the branch to receive the seed, because it is thus preserved from an accumulation of rain water, and is shaded from the sun.

FLOWER-GARDEN PLAN (F. W. B., Weston-super-Mare).—We have no fault to find with your plan only that you are attempting too much in such a small space, and must use very low things for beds 2 feet across, and divided by walks 2 feet wide. We think that a plan with half the number of beds would suit better, and you have done this so well that we are sure you will do that well too. Your two circles, 5 feet in diameter, as two centres, are already large enough for the other beds, and raising them with stakes or otherwise will make them still more conspicuous, and so far drown the other beds. If these two circles were 3 or 3½ feet in diameter, and raised at the sides 1 foot, and covered with small-leaved Ivy, and the other 18 inches added to the surrounding beds, the effect would be better. In either case they will form stand-objects. Unless very steep, we have no fear of the bank if there is good soil beneath the turf. We should like to know the slope, the size of bank, &c., before recommending Deodars, Wellingtonias, &c. If you send a stamped envelope with your direction you can have the plan returned.

FUCHSIA CULTURE, &c. (Nash).—You can have "Florists' Flowers for the Many" free by post from our office if you send five postage stamps with your direction. It details the culture of the Fuchsia. Rose seed does not require to be sown in heat. Hardening-off is gradually lowering the temperature and giving air more freely to plants, to prepare them for enduring exposure to out-door growth.

**PEERES' BOILER (T).**—Our correspondent wishes to know from some one who has tried it whether the flue-pipe joint leaks, how it is cleaned, and how the hot or flow-pipe is jointed?

**OUTVIRANDRA FENESTRALIS (A Constant Reader, Tunbridge).**—You cannot do better than pursue the system adopted at Lady Dorothy Nevill's, at Dangstein. It is there grown in a tank, in which is a depth of 16 or 18 inches of water, which is occasionally flooded to remove the scum. The temperature of the water ranges from 60° to 65°, but that of the atmosphere of the stove is, of course, much higher. The pot should be submerged. The plant may also be grown very well in wide bell-glasses.

**EARLY POTATOES AND PEAS (A Subscriber).**—By out-door culture in the south of Ireland you ought to have them as early as in southern Cornwall. No varieties will come earlier than the true Walnut-leaved Kidney Potato. Of Peas, Dillistone's Early, Sangster's No. 1, and Early Ringwood, succeed each other in the order named; but to have a good succession of first-quality Peas we should grow Dillistone's Early, Sangster's No. 1, Champion of England, and Veitch's Perfection. Of Beans, Marshall's Dwarf Prolific is the earliest; and of Dwarf Kidney Beans, the Black Belgian if you can obtain it true.

**NAMES OF FRUITS (John).**—The Pear was quite rotten when it arrived, but appears to be Beurte d'Areberg. No. 1 (Apple), Colonel Vaughan's; 2, Like Manx Codlin. (H. S. W.).—The Pear is Vicar of Winkfield, and the Apple Scarlet Nonpareil.

**NAMES OF PLANTS (Flora).**—*Dictamnus fraxinella*. We do not recognise the Fern by the name you mention. (X. X.).—*Pteris serrulata*, *Pteris tremula*. Not numbered. (H. E.).—1, *Cyrtomium falcatum*; 2, *Lastrea Sieboldii*; 3, *Adiantum reniforme*; 4, Insufficient. (J. C.).—*Lastrea Filix-mas*. (Alpha).—J, *Diplazium decussatum*; G, *Pteris hastata*; K, One of the forms of *Hypolepis tenuifolia*; H and S, *Pteris cretica albo-lineata*; C, *Asplenium bulbiferum* var.; B, *Doodia caudata*; A, Insufficient; F, *Goniophlebium appendiculatum*; D, *Alosorus crispus*; E, *Asplenium viviparum*. We cannot return specimens.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### THE DEPARTED YEAR.

THE old year with its joys, troubles, and experiences is passed away. Its successor now presides; and we have as usual to express our thankfulness that we have been spared to address our readers once more, to tell them of our success, to thank them for their support, and to offer them our good wishes.

The course of the poultry world has been smooth during the year 1864. The promises of 1863 have been kept. The new classes that were demanded have been well filled with entries; the love of the pursuit has been increasing; and we believe we may fairly and truthfully say that at no previous period have there been as many new exhibitors coming forward. The old shows are well supported when they are well managed. Entries are numerous, and the attendance good.

All great changes must be more or less progressive. When poultry first became a popular question, all that was asked for was a breed that would sell well at an exhibition or in a sale-room. No heed was paid to the food part of the subject, nor was the fitness of a breed either for a peculiar climate or purpose ever thought of. It is now different. When a new one is introduced, one of the first inquiries is, Is it a good table bird? The deviation of its popularity or its claim on the public favour will depend on its useful everyday qualities. This will be more clearly shown as we review the different breeds, and notice the position they hold or have held in the public estimation.

Dorkings are nearly perfect in every way. They are large, handsome, heavy, and healthy. They form the most numerous class at all shows, they sell readily, and are evidently favourites with those who wish either for sale or consumption to produce the best quality of poultry. The old-established names are still in front, but they have new colleagues in the prize list. Lady Holmesdale and Captain Hornby are the first in this breed.

Spanish have made a large stride, and have certainly shown better in quality and condition than for several years past. If they keep on, the days of Messrs. Davies and Rake will be seen again in this beautiful breed. Mr. Jones has been at the head of the chickens at Birmingham and Manchester. The entries have been good, except in the hen and pullet classes, which do not fill as they should.

Cochin-Chinas keep on their steady way, and form, deservedly, a valuable addition to our shows. Captain Heaton has repeated his 1863 victories, and been the principal prizetaker wherever he has shown. The quality of the birds has been excellent, and the above-mentioned victories have not been easy achievements; worthy competitors have been found everywhere. We can note little progress in the Grouse and Partridge breeds; but we can speak most

highly of the advance in White; they have been excellent and numerous.

Brahma Pootras have outlived their detractors with few exceptions, and show, on all occasions, numerous pens of uniform plumage and great beauty. It is now well understood, and thoroughly believed, after trial, that few birds are so hardy or so profitable as these.

Malays seem limited to a small number of pens, and find but few admirers.

Creve-Cœurs have not been as numerous shown as we expected.

We can speak of Hamburgs as we have done for many years. They vary, and no improvement can ever be noted in all varieties at the same time. This year our highest praise will be for Golden-pencilled, Golden-spangled, and Black. The latter had separate classes at Birmingham, and filled them well, not only in numbers, but in quality. The Golden-pencilled and Spangled have been nearly perfect, but the Silvers have lost ground.

Game fowls are always beautiful, and this year has been no exception. Mr. Statter has been very successful. Many of the winners in the north have been of Mr. Archer's celebrated strain. At the large shows the various classes of this beautiful breed have formed an exhibition of themselves.

Bantams have marvellously increased in the Game classes, and they are birds of perfect beauty and symmetry. Blacks and Whites also increase, but the beautiful Sebrights seem at a standstill as to numbers.

Turkeys have hardly held their own in weight. The same may be said of Geese, with few exceptions. Rouen Ducks go ahead in weight and numbers. They are far more numerous than their Aylesbury competitors, and bid fair to be as heavy. Buenos Ayrean Ducks daily gain more admirers.

Shows are becoming more numerous in connection with agricultural meetings. In the north of England they are well established, and, though of frequent recurrence, they are well supported. They make little progress in the south and south-west. We cannot tell why poultry should be unpopular with the farmer, but it is so; and hence the fact that in a few months of the year we import many millions of eggs. An attempt has been made to get up a Metropolitan Show at the Agricultural Hall, but the time of year was unfavourable, and the attendance was bad. Birmingham thrives as ever. Entries are more numerous, so are sales; more visitors attend, and more money is taken.

The Poultry Club has given signs of life during the past twelve months, and if it be for the good of a pursuit in which we are much interested we heartily wish it success. We do not think it will conduce to such an end by censuring the management at Birmingham in the appointment of Judges. They have been the same for many years, and it has moved only from success to success.

This nearly brings us to a close. Our subject has been of peaceable times and doings. We are grateful for it. We are thankful our task involves nothing more—that with the end of the year, while we have grateful recollections of past pleasures and associations, we can hardly recollect a difference—certainly we have had none that will live in our remembrance. We tender our best thanks to many valuable and able contributors, especially for the kindly spirit in which their instructions are given. We admit our obligations to an increasing list of subscribers. We are thankful for the satisfaction which these things bring, grateful for the prosperity which results from them, and hopeful for the future. It is always a happiness to us that to the best of our ability we seek to give pleasure to all, and that it is our good fortune to be the means of diffusing knowledge that is not only useful but perfectly innocent.

Most heartily do we wish to all with whom we have in any way to do

A HAPPY NEW YEAR.

### BRAHMA POOTRAS.

I MUST leave all impartial readers of "our Journal" to decide, whether in my late defence of the purity of the Brahma I used the word "hybrid" erroneously. The course was forced upon me. All who possess a copy of the beautiful "Poultry Book," I refer to the few words devoted

to Brahmas. They will there see that the word "hybrid" is used by "our Editor" in reference to the Brahma, closely following suggestions as to the probable crosses of Malay, Dorking, and Cochin which might make a Brahma. In these remarks the word "hybrid" has no reference to the Brahma being derived from a cross between a Pigeon and a Pheasant, or a Galena and a common hen, or any such cross of different genera, but to its production from various known breeds of fowls. I cannot see then, as I was quoting from the "Poultry Book," and arguing from its words that I was in error thus far.

I would bow to any ornithologist who had Brahmas and Cochins to decide upon, only I would place this before him—given a Buff, Partridge, Cinnamon, Black and White Cochin cock, and a Brahma cock—if they are the same breed, why is it that the Brahma cock differs from all the other varieties of Cochin in the form of the back, brows, and tail? I have read again all that the "Poultry Book," says about Brahmas, and I cannot find there any admission on the part of Dr. Bennett, as to the cross in the origin, and our experience of Yankeedom is not in favour of their truth, especially where money is to be made.

I may add further, that I hatched two chickens last year, the produce of a Brahma cock and Black Cochin hen, that one of these was a correctly marked Brahma cockerel with a single comb, the other a black hen with silvery hackle and pea-comb; that, I should say, these birds partook more of the Brahma than Cochin, and that if the Brahma is already partly Cochin, this result ought not to have been arrived at.

Another question arises out of this discussion. Are not all our known breeds of poultry more or less manufactured? If I am forced to say the Brahma is, my judgment would be that all are, and if so, Why this raid against the Brahma only? Why, if it is conceded to other breeds, that by their breeding true to feather, &c., they have established themselves, is it not also allowed to Brahmas? It savours somewhat of jealousy. The progress of the Brahma in public favour the last two or three years has been so rapidly upwards that we can read, that at Brighton the "great feature" of the Show was—Cochins? No! they only mustered for all varieties of colour eight pens! Dorkings? no, again! but Brahmas, which mustered twenty-eight pens against the small entry of Cochins!—Y. B. A. Z.

[There is no "jealousy" actuating us, we merely wish to arrive at the truth on all subjects within our province. Dr. Bennett's statement that the parents of the Brahma Pootra were a Cochin-China and a Chitagong is in a work published by himself. There is no force in the result of the cross between a Brahma Pootra and Cochin-China, for the same would happen and does happen often when other related varieties are crossed. It is quite probable that many of our breeds of poultry are mere varieties, the results of crossing, but the difficulty is to discover which are the original species. If the Brahma Pootra is a bird of superior merits, it will matter nothing that it is a variety of the Cochin-China.]

## POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.

(Continued from page 520, Vol. VII.)

### GENERAL RULES TO BE OBSERVED IN POULTRY BREEDING. THE BREEDING-STOCK.

1st. The hens selected to breed from should be kept apart from the cock until they are at least twelve months old, and the cock should not be less than eighteen months old before he is put with hens, as a too early call on nature degenerates the breed.

2nd. Whatever races are selected they should be the most perfect specimens that can be obtained, as the first outlay will well repay itself.

3rd. That the distinct races be kept strictly separate, except where it is intended to obtain a cross breed, and for this the finest specimens of both races and sexes must be selected.

4th. Not more than six hens should be allotted to a cock.

5th. After the third breeding year it is advisable either to sell the stock or to fatten them for the market, as they become less prolific, and their progeny are apt to degenerate.

6th. The eggs should be collected at least three times

a-day, as when a fecundated egg has been sat upon for a few hours the germ very soon becomes developed, and the egg is afterwards unfit for hatching.

7th. The stock must be fed regularly at sunrise, and in the afternoon an hour before going to roost.

### THE LAYING-STOCK.

1st. When it is intended to sell the eggs for consumption, it is advisable to pen hens up without a cock, to prevent the eggs being fecundated, as they will then keep fresh much longer. This system of keeping hens by themselves has another great advantage, as they will lay a great many more eggs during the year.

2nd. From twelve to eighteen hens can be kept together in a home as shown in figs. 7 and 8.

3rd. The eggs should be collected twice a-day.

4th. For feeding the same rule applies as above; and the reason for selecting sunrise and afternoon for feeding is, that it is before and after the laying time, during which the hens on their nest would receive no food.

### THE CHICKENS.

1st. From the day they are hatched to the time when they begin to roost, not more than twelve chickens ought to be kept in one compartment, as they will huddle together, and the weak ones either be crushed or suffocated.

2nd. The place to which the young chickens retire ought to have a dry floor, and be kept scrupulously clean; and as the floor is the coldest part of a room, their roosting-box ought not to be more than 12 inches high, and the top to be slanting, which will keep the warm air in the roost. See fig. 12.

3rd. As soon as they begin to roost on perches they should be removed to the poultry-home—say about thirty to each home.

4th. When the cockerels can be distinguished from the pullets, they should be penned separately. From this stock the breeding and laying stock will be selected to replace old ones.

5th. The feeding of chickens ought to take place not less than three times a-day, and be of a liberal kind, with plenty of finely-chopped green vegetables, and an occasional supply from the vermin nursery, but no meat should be given.

6th. Occasionally a little flowers of sulphur and oxide of iron mixed with their food will keep them in good health. Sulphate of iron and lime water are likewise given with great advantage in their drink; this applies also to all kind of poultry.

### THE LAYING OF EGGS

Takes place in the morning during the summer months, and gradually later in the day as winter approaches, until moulting time arrives, when the hens cease laying till they have their new feathers, or for about two months. Although a hen can only lay a certain number of eggs during her life, yet her laying may be stimulated by an appropriate diet (see "Food for Laying-fowls"), as also by a genial temperature kept up in the poultry-home. It has been satisfactorily proved, that under such circumstances a hen will lay at least thirty eggs more during the winter months, a time when they are most valuable, both for artificial hatching and consumption; and taking an establishment with two thousand laying, and one thousand breeding-hens, the extra profit will be as follows:—

EXTRA REVENUE.	
3000 Hens at 30 extra eggs = 90,000; at 15s. per 100 .....	£675 0 0
EXTRA EXPENSES.	
Fuel, wear and tear, during four months .....	50 0 0
Or a net extra profit of .....	625 0 0*

to be ascribed solely to a warm temperature and appropriate diet. But this is not the only advantage derived from a genial temperature during the winter months—it may save, perhaps, hundreds of pounds in the loss of poultry, from diseases caused by exposure to damp and cold.

Just as the laying can be forced by artificial means, so can it also be retarded. When it is intended to keep some

\* We must warn our readers against our correspondent's profit and loss calculations. He makes no allowance for deaths, and other large deductions. Eds.

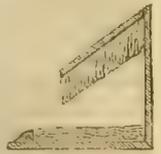

Fig. 12.—Section of roosting-place for young chickens.

hens for laying during the time that others are moulting, which generally begins in September, it is only necessary to pull out the feathers of such hens, and thus produce an artificial moulting about two months sooner—say early in July, when they will cease laying until their feathers have grown again.

THE OVARIUM.

It has been ascertained that the ovary of a fowl is composed of six hundred ovules or eggs; therefore, a hen during the whole of her life cannot possibly lay more eggs than six hundred, and which in a natural course are distributed over nine years in the following proportions:—

	Eggs.		Eggs.
First year after hatching	15 to 20	Sixth year after hatching	50 to 60
Second ditto	100 to 120	Seventh ditto	35 to 40
Third ditto	120 to 135	Eighth ditto	15 to 20
Fourth ditto	100 to 115	Ninth ditto	1 to 10
Fifth ditto	60 to 80		

It follows that it would not be profitable to keep hens after their fourth year, as their produce would not pay for their keep except when they are of a valuable and scarce breed.

PRESERVATION OF EGGS.

Much has been written about the preservation of eggs, and many are the suggestions that have been made, but none have as yet given satisfaction, and for the sole reason that the structure of the egg is not considered in relation to the physical and chemical laws which govern evaporation, permeation, and putrefaction. The shell of the egg being porous to admit air to the chicken during the process of incubation, allows also part of the liquid to evaporate, and the air to penetrate, when the eggs are not used soon after being laid; and the air acting on the animal matter produces early decomposition and putrefaction, particularly in fecundated eggs, in which the germ is first decomposed, clear eggs, the produce of hens which have not been with a cock, keeping fresh much longer. This can be easily exemplified by putting an old fecundated egg, and an old clear egg under a hen when sitting, and it will be found that after the twenty-first day the fecundated egg is putrid, and the clear still fit for use.

To exclude the air from the egg, and to prevent the evaporation of its liquid, it has been proposed by some writers to pack the eggs in salt, lime, bran, sawdust, &c., by others to keep them immersed in lime water, in salt water, or both combined. Others, again, suggest to varnish or oil the eggs, and some even to parboil them.

There can be no doubt that were the object in view solely to preserve the eggs from becoming putrid, some of these suggestions might be employed with advantage; but there is more required than simply to preserve the eggs from putrefaction; for instance, for kitchen use, and the breakfast-table, eggs ought not only to be preserved fresh, but also free from any foreign flavour, such as lime, salt, bran, sawdust, varnish, and oil, must unavoidably impart to the egg through its porous shell; and as for breeding from such preserved eggs it is out of the question. Whoever has seen any chickens hatched from salted or mouldy eggs, or from such as have been varnished or oiled? which latter process stops up the pores through which the air so indispensable to the formation and development of the chicken must be admitted.

Now, the most effective, simple, and economical plan for truly preserving eggs, and without imparting to them any foreign flavour, or rendering them unfit for hatching purposes, is to use the patent stoppered glass jars with vulcanised india-rubber joints (see fig. 13), and proceed thus—Immediately after collecting the eggs put the jar in hot water, and when thoroughly warm so as to rarify the air, place the eggs in the jar, the pointed end uppermost, and pack and line with paper shavings, or cocoa-nut fibre, to prevent them from breaking, then close the jar before taking it out of the water, and it will be found that eggs preserved by this method will be fit for hatching twelve months after, and that those intended for the breakfast-table will be as fresh as on the day they were laid.—G. K. GEYELIN, Civil Engineer, London.

Fig. 13.

HECKMONDWIKE POULTRY SOCIETY'S SHOW.

THE annual meeting of the above Society was held on the 26th ult., at the Wool Pack Inn, in a large room recently built for public use. The day being frosty and clear, and a holiday, the number of visitors was larger than at any previous exhibition. This being a kind of mutual help society, the object of exhibitors is not so much to obtain large money prizes, as to ascertain the comparative merits of the fowls exhibited, the best of which often change owners, and again appear in different hands the next time they are exhibited. This year several pens were sold, and at the close of the Show were forwarded to their new owners in distant parts of the kingdom. The prices obtained were in most cases good, a Cochin Bantam fetched £7 10s. The number of pens was larger than last year, and with the exception of Class 17, Game hen of any colour, each pen contained a single cock bird.

The Game classes were well filled, fully one-half of the pens were occupied by them. In the Black-breasted and Brown Red classes, the Judges found it no easy matter to decide which should take the prizes. The highly commended birds were truly excellent. The Duckwings were a superior class, and in excellent feather. In the Game Bantam classes the birds were first-class, and at the close of the day we found that several pens had changed owners. The Blacks were fine specimens, such as it is no easy matter to beat. Some good Whites were shown, but this district is too smoky for them to look clean. The Spanish class contained some excellent birds, but the entries were few. We were disappointed in the *Hamburgh* classes; as these have here always been called "the cottager's fowl," we expected to find the entries in greater numbers. *Cochin* and *Brahma* *Pootra* entries were few, but the birds were good. The class for *Game Hens* of any colour was a most interesting one, the prize-takers nobly won their honours.

GAME COCKS (Black-breasted Red).—First, R. Hemingway, Shelf. Second, J. Firth, Halifax. Highly Commended, G. Helliwell, Sheffield; A. Hodgson, Iltingworth. Commended, B. Naylor, Heckmondwike; J. Joy, Liversedge Hall.

GAME COCKS (Brown Red).—First, H. C. Mason, Drighlington. Second, J. Fell, Adwalton. Highly Commended, G. Helliwell, Sheffield; J. Riley, Chickenley. Commended, G. Noble, Staincliffe; J. Brook, Gomersal.

COCKS (Duckwings and other Grey and Blue).—First, W. Whiteley, Liversedge. Second, J. Fell, Adwalton. Highly Commended, G. Hartley, Gomersal; J. Riley, Chickenley. Commended, J. Alderson, Halifax; W. Bentley, Scholes.

COCKS (White and Pile).—First, T. J. Sunderland, Coley Hall. Second, H. C. Mason, Drighlington.

COCKS (Black and Brassy-winged).—First, J. Vickerman, Chickenley. Second, J. Brook, Gomersal. Highly Commended, G. Helliwell, Sheffield. Commended, G. Noble, Staincliffe.

BANTAM COCKS (Red Game).—First, G. Noble, Staincliffe. Second, J. Fell, Adwalton. Highly Commended, J. Elam, Heckmondwike. Commended, J. Firth, Halifax; G. Helliwell, Sheffield.

BANTAM COCKS (Duckwing Game).—First, H. Oldroyd, Heckmondwike. Second, E. Wright, Staincliffe. Highly Commended, C. Smithson, Heckmondwike. Commended, G. Helliwell, Sheffield.

BANTAMS (Black).—First, T. P. Preston, Heckmondwike. Second, H. Oldroyd, Heckmondwike. Highly Commended, J. Brooke, Heckmondwike.

BANTAMS (White).—First, G. Helliwell, Sheffield. Second, H. Oldroyd, Heckmondwike. Highly Commended, G. Preston, Heckmondwike.

SPANISH (Black).—First, J. Beaumont, Dewsbury. Second, J. Vickerman, Chickenley. Highly Commended, J. Oldroyd, Dewsbury Moor.

HAMBURGH (Spangled).—Prize, G. Helliwell, Sheffield.

HAMBURGH (Pencilled).—First and Second, S. Smith, Northowram.

COCHIN-CHINA (Any colour).—First, G. Helliwell, Sheffield. Second, C. Lister, Mirfield.

BRAHMA POOTRA COCKS.—First, C. Lister, Mirfield. Second, A. Tattersfield, Heckmondwike.

ANY OTHER DISTINCT BREED.—First, C. Lister, Mirfield (Sultans). Second, G. Noble, Staincliffe (Cochin Bantams). Highly Commended, S. Halliday, Heckmondwike. Commended, W. Leadbetter, Mirfield.

GAME HEN (Any colour).—First, H. C. Mason, Drighlington. Second, G. Noble, Staincliffe. Highly Commended, G. Helliwell, Sheffield; T. Atkinson, Heckmondwike. Commended, A. Tattersfield, Heckmondwike; T. J. Sunderland, Coley Hall; J. Harrison, Holbeck.

The Judges were Mr. J. W. Thompson, Southowram; and Mr. Enoch Hutton, Pudsey.

BRAHMAS.

ALTHOUGH we have heard lately of the funeral rites, &c., as connected with this "mongrel lot," although the attorney-general, and we presume his client, are both gone to the tomb of all the Capulets like weeds, I suppose these "mongrels" are very difficult to eradicate. I refer my reverse "Z. A. B. Y." to the Brighton Show. There Dorkings—

Dorkings do I write? aye Dorkings in a southern county, the fowl, *par excellence*, for the south, &c.—had two classes, and £12 offered. They mustered 35 pens.

The "cross-breeds" had £3 10s. offered, and they mustered only 28 pens! Do we need any further facts, that in a "southern" county these "mongrels" ought to remain unnoticed? Why do persons keep such wretched birds? Strange, no other breed came near this unpopular fowl as a payer to the show, and in the prize list eleven pens were mentioned in one class, and six in two classes of Dorkings!

The coffin does not appear to have been strong enough!—Y. B. A. Z.

THE Brighton Poultry Show has afforded another, and, I trust, a conclusive proof of the growing popularity of the Brahmas, and of the especial esteem in which they are held in the south of England. It also proves conclusively the necessity for dividing the Brahma class at any first-rate show, as has been already done at Islington and Manchester. The following are the numbers in each class:—

Brahmas.....	28	Silver Hamburgs .....	11
Coloured Dorking Chickens ...	22	Cochins .....	8
Bantams .....	17	Spanish Chickens.....	8
Coloured Dorkings .....	13	Dorking Cockerels .....	7
Any variety .....	13	Spanish .....	6
Game .....	13	Polish .....	6
Game Chickens.....	11	Game Cocks .....	3
Gold Hamburgs.....	11		

It will be seen that the Brahma class was the largest in the Show, beating the Dorking chickens by six, the Bantams by eleven pens, and more than doubling any other class. As to quality, it is sufficient to say, that eleven pens of Brahmas were noticed by the Judge, being treble the average number noticed in the other classes.—BRAHMA FOOTRA.

## A NEW CHAPTER IN THE NATURAL HISTORY OF THE BEE.

### BEE COMMOTIONS AND QUEEN ENCASUREMENTS.

THIS is a new chapter in apian science, and future historians who would take up the pen to write a systematic and comprehensive treatise on the honey bee must, if their knowledge is not behind the age in which they live, devote a whole chapter to the consideration of the very interesting and novel subject—bee commotions and queen encasements.

The manuscript which forms the substance of a portion of the following article has lain aside in my repositories for several years, and was not, therefore, originally intended for THE JOURNAL OF HOETICULTURE. The peculiar and hitherto mysterious facts to which it makes reference are of such a character that I confess I felt somewhat unwilling publicly to hazard a theory regarding phenomena which further investigation and a more enlarged experience might possibly cause me to alter or abandon. Moreover, at the period referred to, the subject itself had apparently escaped the attention of both the naturalist and practical bee-keeper—no British author, to my knowledge, having taken any notice of it, and no apian I ever met having made it a matter of study or investigation. I believed I had made a discovery of a very peculiar character—a discovery of certain strange phenomena occasionally occurring in the apiary in regard to which the queen occupied a prominent part, and which were evidently caused by something affecting her circumstances or condition. In this Journal I have more than once hinted at the subject, and in the concluding paragraph of an article written by me in No. 95 (20th of January, 1863), I stated that in investigating the curious phenomena in question I had bestowed considerable attention and thought, and though I could not say that I had been able to unravel entirely the true solution, yet if ever induced to take up pen to endeavour to cut this Gordian knot, to unravel this physical mystery, I should describe the subject of my essay to be "A New Chapter in the Natural History of the Bee."

While now, therefore, taking up my pen in fulfilment of this promise to narrate the results of my experience on this interesting subject, I have thought it better to preserve, as I have already said, a portion of the original manuscript referred to, if for no other purpose than to show the changes

which my own views have undergone in the course of my investigations: these extend over a period of some eight or ten years. It is with diffidence I confess that, even now, I attempt a solution; for I know\* that the subject in some of its aspects has not only been brought before the readers of this Journal in 1862 by that indefatigable and minute apian observer Mr. Woodbury, but has also I notice been a theme of controversy among the leading apianians in Germany.

Few naturalists or bee historians seem to take any notice at all of what I choose to designate "bee commotions and queen encasements," or if they do, it is only in an incidental manner, and in reference exclusively to such commotions as follow the loss of a queen. There are other commotions, however, which take place in the apiary, and which the observant cultivator will not fail to notice, although he may not consider them of sufficient importance thoroughly to investigate and explore. My attention was early directed to the consideration of these, but for a long time I was at a loss to account for them; they appeared to me a perfect enigma, and wrapped up in profound mystery.

To such as are not well versed in the habits of the bee I may explain that there are three kinds of commotion which may occur in a hive, and which differ from each other in some essential particulars. It is only the intelligent observer, however, that can discriminate between them. The one which is most palpable is that which takes place under the following circumstances. Suppose the queen to be removed from a swarm newly hived, what takes place? The bees very soon thereafter on becoming aware of the loss get agitated, run about in all directions throughout the hive, explore every corner in quest of her. The agitation increases as the knowledge of the loss extends itself among the masses. The bees rush furiously out and in at the entrance, flying about in all directions, until, despairing of finding out their lost sovereign, they desert the hive in a body, and after filling the air in wild confusion return to the parent hive from which they had primarily issued. The origin of this commotion is quite manifest to the merest tyro in bee-knowledge.

Another kind of commotion occurs from a like cause, the loss of the queen, but under different circumstances and conditions, and the commotion among the bees will consequently manifest itself in another form. Suppose you remove the queen in the summer months from a healthy stock hive containing eggs and brood in all stages, what follows? In a short time—in less than half an hour, perhaps—manifestations of the loss will be observable. The bees will become agitated; the younger bees, especially, will be seen running out and in at the entrance, restless, and searching all over the hive in quest of their missing sovereign. The commotion in this case, however, is partial only and slight when compared with the former case, and its character will be more or less influenced by the condition and circumstances of the hive for the time being. In such a case as the one now supposed the commotion generally subsides in a short time, indeed, it is sometimes so slight as often to attract little notice, even by the more observant; for, with the exception of the younger bees occasionally afterwards displaying signs of agitation and restlessness, the industry and work of the hive are otherwise unimpeded, and all will apparently go on as before. The difference in the character of the commotions in these two cases lies in this—that in the latter there are in the hive materials out of which the bees can repair the loss they have sustained, and rear for themselves a new and youthful successor, which in due time will exercise all the functions, and discharge all the requirements of queen and mother. If such materials, however, be not present in the hive in the case supposed; if, for instance, the queen die during winter or early spring, or late in autumn when no such eggs or brood exist, then so soon as the bees become cognisant of the loss the commotion will assume a more aggravated form, and be more tumultuous in its character. Great excitement will prevail throughout the entire hive, which extends sometimes over several days, during which period I have often witnessed partial

\* In May, 1863, Mr. Woodbury wrote me "I wish you would take up your pen and endeavour to unravel this mystery, which is a complete puzzle to me." The Numbers containing notices both from his pen and "INVESTIGATOR'S" were kindly sent me by the Editors for perusal.

and almost entire desertions take place. Moreover I have noticed when the loss of a queen occurred during winter or cold spring that the commotion indicating the loss did not occur immediately after the event, but often weeks after it. The first fine mild day afterwards will generally be that on which the commotion will show itself. Of course, when the loss of a queen takes place in such circumstances, desertion or a dwindling away necessarily follows, and the hive perishes.

But there remains to be considered another class of commotions differing essentially from either of those described, and to the consideration of which this article has chief reference.

From a very early period in my study of the history and habits of the bee my attention was drawn, as I have before stated, to the theory of commotions. I had frequently observed their occurrence in my apiary at certain seasons of the year, in spring and autumn particularly, and no season passed over without revealing to me some form or aspect of these curious phenomena.

The general characteristics of these commotions are somewhat identical to the second modified class already described; but, as in these, the agitation is not so widespread, but is confined, frequently at least, to a comparatively small number, and among these the younger bees always appear the most conspicuous. But what distinguishes this class of commotions from all others is the peculiarly strange and fluttering noise which may be distinctly heard in the interior—a noise so peculiar as unmistakably to point out and indicate to me the true nature of the case, and prove without any further evidence the real state of matters within. On such occasions I have noticed the bees fly about as if examining, or wishing to gain access to, other hives, and so very agitated and excited do some of them become that I have observed them recklessly dash out of the hive, even after twilight, and lose themselves in the darkness of the night. In such cases I have had to close the entrance to prevent loss of bees till morning, when quiet was generally restored.

The first opinion I entertained in my early experience regarding these strange commotions was that they always indicated the loss of the queen; but this view I was obliged to abandon, from the simple fact that the hives in which they occurred did not often perish, as they would probably do at certain seasons of the year in such an event, but generally quieted down and recovered, though sometimes slowly, strength and activity.

In 1856 I began to investigate these commotions minutely, and took notes in my journal accordingly of all cases occurring in my apiary with a view to a solution.

The first recorded by me, therefore, is under the date of the 7th of March, 1856. On this date I observed No. 5, straw hive, one of the strongest in my apiary, in a state of commotion. The bees, especially the younger ones, were running about in a confused manner, taking wing, and apparently deserting into other hives. I turned up the hives, and found the bees in a turmoil searching all over the interior. I could see, however, no trace of a dead queen. In the evening, on listening at the entrance, a doleful fluttering noise was heard within, and the bees, though quieting down at intervals, yet again and again renewed the excitement till late, when several rushed out, and lost themselves in the dark. I accordingly shut the hive up till morning, when I intended to give it the queen of a hive whose numbers were now so reduced as to render its recovery very doubtful. This I did on the supposition that the queen had been lost. I introduced the queen first at the entrance for ten minutes; I turned up the hive to see how things were doing, when I found the queen surrounded by two or three dozen bees, which had hedged her in so closely that I feared she might be suffocated. In endeavouring to disperse the cluster I found the queen was held a complete prisoner. The bees stuck to her like leeches all round, holding her by the legs, wings, &c., and attempting apparently to sting her. I succeeded in extricating her, and shortly afterwards introduced her at the opening at the top of the hive. Here her presence acted like magic, the bees became perfectly furious, attacking her with the greatest ferocity, while others pursued her as she descended among the combs, apparently with the most hostile intentions. Next day the hive quieted down, and some days after I found a dead queen extruded. Although I could not determine whether this queen was the

one I had introduced to the hive or not, this is of little moment as the future history of the hive demonstrated that a queen was retained, proving that the commotion arose not from the want of a queen, as I at first supposed, but from some other cause not yet determined. The age of this queen was unknown, but she had been in my possession for two years.

The next case I noticed occurred on the 8th of December, 1856. I observed hive No. 3 in great commotion, the bees running to and fro in great excitement, and several flying off even after dark, and losing themselves. I shut the hive up to prevent loss of bees, and quiet was restored by the following morning. On the 29th of April, 1857, I find the following remarks in my journal in reference to this hive:—"Notwithstanding the commotion in No. 3 on the 8th of December last, and my fears as to the loss of its queen, this hive shows numbers of young bees, and works as actively as any in my apiary." This queen was reared in 1854, and, consequently, was between two and three years old.

Cases of a similar character occurred in my apiary on the 7th of April and 8th of December, 1857. The commotions exhibited were of the same character, and though no bad results immediately followed these, yet the after-history of both the hives in which they occurred was far from being satisfactory. Neither became populous in season, and I now began to view commotions in general as omens of present or impending evil, and, consequently, as unwelcome phenomena in the apiary.

On a commotion occurring in a hive on the 13th of October, 1858, I took a queen out of a unicombed hive, and introduced her to the bees to see how they would receive her. They immediately attacked and encased her. On my releasing the queen I think a bee had stung her. I then restored the hapless queen to her own hive again; but now her own subjects became excited, and surrounded her, from what motives it were difficult to say, whether on account of her having undergone some apparent change by virtue of the encasement itself, or, more probably, from the fact of her being wounded. Certainly I have noticed on several occasions injured bees—such, for instance, as had their wings singed off by a lighted candle—become the objects of a reckless attack by their comrades, and fall victims to their fury. I ascribed this, however, to what I would call an irritable inadvertence. Mr. Woodbury, I think, narrated a similar instance to the above in his experience, where a queen, after having been encased in a strange hive, and evidently, I think, wounded, was, on again being restored to her own bees, surrounded, and next morning extruded dead.

Having satisfied myself, therefore, that these strange phenomena which manifested themselves from time to time in the apiary had generally nothing to do with the queen, another view of the matter presented itself to my mind, and which might, I thought, lead to a solution of this curious problem, I had observed that in the course of some operations which I was in the habit sometimes of performing in my apiary—such as driving the bees for experimental purposes, changing the site of a hive, or such like—a number of the bees in such circumstances generally found their way into neighbouring or contiguous hives, and created by their entry some confusion and disorder; and it may be remarked that in cases of this kind the bees so entering are not always treated with hostility as are robber bees or entrants under other circumstances, but, on the contrary, their accession is often received joyfully, and a complete fraternisation takes place. Still the bees so entering naturally find themselves, to use a common but applicable phrase, "in the wrong box," and before they are reconciled to the change they will exhibit a restless and agitated appearance, which, however, disappears on the bees failing to discover the whereabouts of their former comrades. This view seemed at first sight plausible enough, and the following incident which occurred in my apiary seemed rather to strengthen it.

It so happened that after performing an operation on one of my hives a commotion on a small scale took place in a Huber-hive adjacent. The circumstance of the commotion occurring in such a hive was fortunate. A favourable opportunity was here presented to me of ascertaining how matters really stood in the interior. I immediately opened up every leaf or division of the hive, and examined each *seriatim*. I found the bees running over the combs in an agitated state, but could see no queen. My first impression was that the

queen was really amissing, but on searching more minutely I discovered a small knot of bees densely crowded together. In the centre of this cluster I found the queen, apparently held a fast prisoner; so closely packed were the bees around her that it was with the greatest difficulty I could get them disentangled from each other and from the queen, which they adhered to most tenaciously. With a small twig I forced the reluctant bees to quit their hold, and set the queen at liberty. She moved off among the combs, and the hive immediately afterwards assumed its usual quiescent state. I greatly rejoiced at this discovery, and I imagined that the mystery of commotions was now solved. I thought that if the queen was thus surrounded and held a captive by foreign or stranger bees, the agitation got up in the hive was very natural, and what might in the circumstances be expected. But the question arose, Were the bees clustering around the queen really her foes? Might they not be her friends? What object had the bees in so surrounding her? Were they hostile to her, or otherwise? Is she really seized and held captive by a few stranger bees which may have accidentally found their way into the hive, and caused all this disturbance? or is the cluster composed of her own subjects gathered around her on some other grounds, and from other motives than hostility? On reconsidering this case, and comparing it with other instances of commotion, I was far from being convinced that the entrance of strange bees produced on all occasions the phenomena witnessed. Moreover, there was something in the circumstances of this hive, and the history of its queen which made me pause before coming to a hasty conclusion on the matter, and though I left it over at that time for further consideration and reflection, I could not help entertaining the notion that the age of that queen might have had something to do with the curious phenomena exhibited, and might afford after all a truer solution of the theory of commotions than the entrance of foreign bees.

On a consideration, therefore, of the whole facts and circumstances connected with the history of commotions, so far as my knowledge then went, I came to the conclusion they were in most part based on the superannuation, debility, and incapacity of the queen. When the functions of mother begin to be impaired through increasing age and infirmity, when she ceases to be productive or prolific, it is then, I thought, that the bees instinctively get alarmed for the safety of the hive. The queen moves languidly over the combs; few eggs are deposited. She is attended still by a few bees that seem anxious to prompt her to the office of mother; but as the brood becomes scanty, and the population goes down, as the queen becomes weaker and weaker, until ultimately she can with difficulty hold by the combs, the bees begin to gather around her with anxiety—perhaps to vivify, if possible, her sinking frame; but nothing can impart vigour to the feebleness of age! She remains inert and languid, the bees gradually cluster around her, and with that loyalty and affection so peculiar to them. The queen being thus encased in a knot of her interested and devoted subjects, and isolated from the presence of the general mass, these get alarmed for her safety, and thus the theory of commotions might, I thought, be satisfactorily explained. The question arises in such a case, Why do the bees not avail themselves of the power bestowed upon them by Nature, and provide themselves timeously with a successor? This is often done, as already illustrated by me in this Journal (September 16th, 1862, No. 77), where I have recorded a beautiful instance of the instinctive foresight in the bee in thus timeously providing against such an impending loss. But though in summer or in suitable seasons this may often occur, yet when the queen gives way, as is often the case in early spring or in autumn, the risk is great of the hive perishing, as the circumstances and conditions of the colony are not then favourable to queen-rearing, and hence a great number of hives perish at these seasons of the year.—  
J. LOWE.

(To be continued.)

### STRAW BEE-HIVES.

A CORRESPONDENT of the *Dollar Newspaper* (American), thus sets forth the advantages of straw bee-hives:—

Straw as a material for bee-hives seems to have been

formerly in much more general use than at present. Bees then seemed to prosper with little or no care on the part of the owner; indeed, many, deterred by superstitious notions, never presumed to invert a stock even for examination, but allowed it to take its chance nearly or quite as undisturbed as if buried in the depths of the forest. How bees could thus subsist, swarming and multiplying their numbers in defiance of the external foes and internal tendencies to disease with which they have ever to contend, I presume may be explained in part, at least, by attributing their prosperity to the straw hive thus employed.

Waiving this question, however, for the present, it is acknowledged, I believe, by the leading apiarists of the country, that if straw could be advantageously applied, no other available material would surpass it. Says the Rev. L. L. Langstroth, on page 331 of his "Hive and Honey Bee." "Straw hives have been used for ages, and are warm in winter and cool in summer. The difficulty in making them take and retain the proper shape for improved bee-keeping is an insupportable objection to their use." Mr. M. Quinby gives his experience as follows:—"A few years since, in connection with a partner, I purchased twenty-two straw hives. These, with forty made of wood, equally as good in respect to the number of bees and stores, were placed in one yard. As the swarming season approached, the straw hives indicated the strongest colonies. The first five swarms were from these hives; and when seventeen had issued, thirteen had come from them. All sent out swarms but two or three, while fully one-third of the wood hives failed to swarm at all through the season. Here was an advantage in swarming, greatly in favour of straw hives. We kept some of these hives several years, which continued to maintain, in this respect, their superiority. Since our trial of them I have inquired of many who have had them in use, and all testify to their early swarming. I think it would be safe to give eight or ten days at least as the average time that these will swarm before others."

The superior value of early swarms will not be questioned. As swarming generally takes place in the height of the honey harvest, when a strong colony will often collect 3 lbs. per day, it follows that a gain of ten days in time is equivalent to 25 lbs. or 30 lbs. of honey, which is again virtually equivalent to nearly as much in the surplus-boxes to be put on after the hive is filled.

### OUR LETTER BOX.

**ESTIMATE OF POULTRY-HOUSE (Inquirer).**—The best mode for you to proceed will be to ask of one or two builders what they would build such a structure for. No professional architect would give an estimate without examining the locality.

**SPANISH FOWLS (Black Spanish).**—They require little run, and do well in confinement, laying freely. No fowls will, however, do well on a brick floor. You must remove it, and substitute good hard beaten earth. The run in front must be provided with bricklayers' rubbish, gravel, grass, and earth, the lighter the better. Spanish do not sit. If they did, the space you name is not large enough to rear chickens. Dust and any kind of light dry earth would be far better than hay. They require a dust bath daily.

**FATTENING DORKINGS (T. Catlin).**—We advise you to buy Mr. Bailly's book on fowls. It can be had at our office price, including postage, 2s. 2d. Fowls whilst fattening should have little or no room, and not much light. They should be kept quite clean and fed three times per day. Only as much at each meal as they will eat up clean. Ground oats mixed with new milk is the best food. They should fatten in a fortnight or, at most, three weeks.

**SATINETTE PIGONS (J. Devonshire).**—We believe Mr. H. Noye is the same as the Mr. Noye who has advertised in this Journal.

**ARTIFICIAL SWARMS—STRAW HIVES—FEEDING (A Novice).**—All the instructions you require for making artificial swarms were given by Mr. Woodbury in No. 161. We do not think it advisable to paint straw hives, which should be carefully protected from the weather by sufficient external coverings. A clamped platform of any convenient size may be readily fixed on the top of a bell-shaped straw-hive by means of common mortar toughened by the addition of a little cowdung. If three or four wood screws are inserted on the underneath side of the platform, and left with their heads projecting about half an inch, they will become imbedded in the mortar, and, in conjunction with the uneven surface of the hive itself, will keep all firm. The hole in the centre of the platform should be 3 or 4 inches in diameter, and a corresponding hole may be readily cut in the hive itself, by means of a sharp pen-knife, as soon as the mortar is set. Feeding bees always excites their appetite for more; but we never noticed that the admiration of barley-sugar caused them to seek water with especial avidity. The barley-sugar barricade was suggested by Mr. Taylor many years before "The Times' Bee-master" was heard of, but we have never tried it ourselves. We should deem the weight of your stocks perfectly satisfactory. Aspect is certainly not of primary importance. Condensed moisture at the hive's mouth is the usual indication of a thriving and populous colony. There is no doubt as to the preference manifested by bees for simple syrup over the bacchanalian abominations advocated by most of the writers of bee-books.

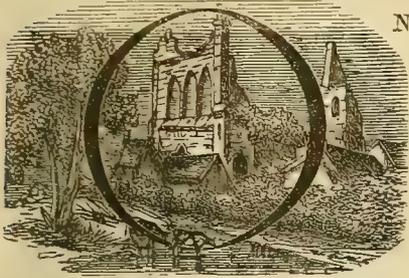

WEEKLY CALENDAR.

Day of M <sup>th</sup>	Day of Week.	JANUARY 10-16, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

16	M	Crocus flowers.	41.7	31.6	36.2	19	1 8	20 4	43 9	28 9	19	10 10	16

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 42.0°, and its night temperature 30.4°. The greatest heat was 56° on the 14th, 1849; and 15th, 1831 and 1852; and the lowest cold, 4°, on the 14th, 1838. The greatest fall of rain was 0.80 inch.

HARDY FERNS:

HOW I COLLECTED AND CULTIVATED THEM.—No. 7.

NE of the greatest difficulties in Fern-hunting is the not knowing what you are looking for, or where you are to find it.

I had never seen *Hymenophyllum unilaterale*, or tun-

bridgense, when I set off one morning to search for it somewhere in the torrent bed of the West Lyn, as it takes its way amidst rock and forest tree, under Lyn Cliff to the sea at Lynmouth. Able-bodied must they be who venture on the like errand; able to contend with a down-hill rush from Lynton, and an up-hill scramble amidst moss-covered rock and leaping waters; now steadying oneself with a branch of an overhanging tree, through which the sunshine gleams; now warily stepping over fissures and chasms, with the river bubbling beneath. And then the grand discoveries and the failures! The learned way in which one strives to palm off some pretty moss upon oneself as the veritable *tunbridgense*, or at the very least *Wilsoni*, with the pleasant and extremely logical argument of "Filmy Ferns are moss-like plants—this is a moss-like plant: therefore this is a *Hymenophyllum*." And then the false argument leading to the true conclusion, for at last in my hand is a large mass of moss-like plants, and lo! it *is* *Hymenophyllum Wilsoni*: and why is it not *tunbridgense*? I have found some of these Filmy Ferns much finer than others, and I call the finest *tunbridgense*; but I am afraid that in reality I have only found the *unilaterale*, and when I have found it I am obliged to own I have never kept it alive for any time. I have planted it on a brick in a running stream, but a rush of water washed it off; I have tried it in a flower-pot with a glass over it, but a little inattention or a visit, and I found it damped off. Still it is worth hunting for, if only to see it at home sporting with *Naiades* and *Dryades*. It seems a graceless thing to take it away to pine and die, either in solitude, or with companions uncongenial to it. I always feel loth to tear the little Fern from the rock it so prettily adorns; there is something sad in the look of the bare uncomplaining stone when the companion that gave it all its beauty and its life is gone.

I was once walking in the country with one who spared himself but little recreation from a life of toil in London—not literary toil only, for the *gamins* of the London streets were gathered into schools and taught by him. It was spring time, and the lanes were sweet with the breath of flowers. By-and-by I spied a *Primrose* root, and as I was about gathering the flowers my

friend said, "Nay, leave them alone, they look so home-like; they did not choose that quiet corner, and deck it out so daintily for you to destroy their labours in a moment. Let it live." Nature, to the toil-worn London man, was a living, breathing Presence; he drank with a thirsty grateful heart at the fountain of her beauty; but he would fain have left the waters undisturbed for the enjoyment of others. Yet we, who boast ourselves such lovers of Nature, are often at best only destroyers.

Lynton and Lynmouth abound in natural charms of a wild and strange character. The "Valley of Rocks" brings to mind a shadow-like memory of the pass of Glencoe, although the "Chimney" and "Castle Rock," "Rugged Jack," and the "Devil's Cheesewring," never rise into the solitary grandeur which leaves Glencoe unsurpassed by any other scene in Britain.

I was not very successful in my Fern hunts in North Devon. I found a small plant of *Adiantum capillus-Veneris* at Combe Martin, and I saw some more, but it was too high for me to reach. The little bay is worth a visit on its own account. And as I sat to rest on a rock above the sea the voices of children, playing with the boats and lobster baskets below, came round me like music, tempting me to descend and survey nearer a picture superior to any in even Collins's happiest style.

A stranger was then a stranger at Combe Martin, and the bright-cheeked urchins left their play, and came running bare-legged out of the water to gaze. "Did I want Ferns?" Presently the happy group were tumbling up the rock I had looked at with such timid eyes; but children's hands are destructive implements, and fronds without roots were the only result of the scramble.

I made another attempt to reach *A. capillus-Veneris* at Ilfracombe, taking with me a lad who seemed ready to climb the side of a house if necessary; but all the available tresses of Maiden-hair had been shorn away, and I returned with only a tinfal of sea creatures to reward me for my pains.

It seems cruelty so entirely to destroy the habitat of any Fern: yet, if the present rage continue, I see no hope of any known species being allowed to remain in its old haunts. The poor Ferns, like the wolves in olden time, have a price set upon their heads, and they in like manner will soon altogether disappear. We must have "Fern laws," and "preserve" them like game.

In the neighbourhood of Ilfracombe I found a few *Scolopendriums* with the ends of the fronds cleft, but they were hardly worth bringing away. I also found *Polystichum angulare* growing in magnificent profusion; *P. aculeatum* was comparatively rare.

Between Launceston and Holsworthy I found the only *Lastrea Fenisecii* I have seen wild in Devonshire; it was growing in an old hedge by the roadside, and the fronds were small and ill-grown, wanting the rich fulness of size and colour that distinguishes the *L. Fenisecii* in Cornwall. There is no mistaking this Fern when you find it. It has the appearance of crisp curled Parsley, so entirely "recurved" is each pinnule.

I have heard *L. recurva*, or *Fœnisecii*, or Bree's Fern, described as very refractory in cultivation, but I have never found it so. It will adapt itself to any situation where there is good drainage; stagnant soil is its death. In dry sunny aspects the fronds of *Fœnisecii* will almost creep along the ground, as if to make a shade for each other. In an open space, where there is shade from a hedge, it will shoot up its feathery sprays of tender green tall and strong, making a very handsome plant. It is always interesting in its growth and habits, and the young fronds are often green in midwinter, and make lovely foliage for the vase. I have never found it on rocks, or in any county but Cornwall, save in the instance I have named, in Devonshire. In cultivating it in Warwickshire, I used a little rich earth mixed with leaf mould.

In Scotland I found a variety of *L. dilatata* with its pinules curved in a convex manner. I showed the specimen to Mr. Bree, and he thought the curved look would vanish with time. This has not proved to be the case, though I have had the Fern for some years. *Lastrea cristata* I have never found, but I have some good plants of it; it increases quickly in cultivation. *L. cristata* has one peculiarity which I have noticed in no other Fern—the venation is clearly defined on the outer side, making a regular pattern on the pinule. This has been the simple mark which has always, and at once, made *L. cristata* known to me. The fronds of *cristata* are slender and pretty, but they are of so fragile a nature that they bow, bruised and broken, before a high wind, so that the plant has usually an untidy appearance in the fernery.

*Asplenium marinum* I found at Exmouth growing on a rock far removed from the sea. It also grows on the coast about Teignmouth, and more plentifully near Dartmouth, that strange old western town, with its ill-conditioned streets, leading nowhere, huddled like waifs by the river side. The best thing to be done when you get into Dartmouth, whether by the pretty river route or by the railway, is to get out of it again by hiring a boat, and rowing to the mouth of the river, where you may pry after *Marinum* in caves hollowed out of the rugged rocks, where fired waves break and die, and sea birds wail their melancholy cry. The coast on the right of Dartmouth begins to assume the characteristics of Cornwall; the red sandstone gives place to granite, and the softer features, that make the charm of Devonshire scenery, disappear altogether. The Devonshire dialect, so soft and courteously misleading, is soon lost in the rougher tongue of the "Tre," "Poll," and "Pens" of the dear Cornish land—a land so separated in the character of its people and natural scenery from the rest of England, that during my first visit to Penzance, I found myself continually saying, "When I get back to England." It is a land of Ferns and wild flowers—a land of old ecclesiastical monuments and wayside crosses. Each village has its history and its records of interest; its church—a landmark to sailors at sea, and to travellers across the waste; its baptistry—the bubbling waters of the clear spring, rising on some dreary moor, guarded by a few rough slabs of stone covered with Ivy and decorated with Fern. The true Cornish man has a rough intelligence that beams on his face, and takes expression in words of singular fitness to the subject which engages him. He has a self-respect that gives to his conversation a freedom unaccompanied by any mixture of vulgar familiarity. Most of the Cornish miners have their bookshelves containing volumes so successfully read that humility keeps pace with the knowledge acquired. This intelligence, with the apt way of expressing it, gives a stamp of originality to the people that you can hardly fail to recognise.

After a visit of some months to Penzance, I went a tour in the north of England, and in going over a silver mine I was accompanied by one of the miners, who explained the different details of the mine, and the processes of refining the silver. At last we arrived at the final process, and saw the silver purified of all its dross. I made some slight remark to the man on the exceeding beauty of the ore, which he instantly answered by saying, "Yes, madam, I trust we shall be found as bright as that when the trials of earth have done their work, and purified all sin from our hearts: we sha'n't think much of the fire we have gone through then." I looked up at the intelligent face, and said, "You are from Cornwall?" He asked me how I knew, for indeed it was so;

and then he went on to tell me of his home and prospects in the country he loved so much better than the north.

"One and All" is the motto of Cornwall, and it expresses much that is pleasing in the character of the people.

The gardens I saw in Cornwall (they were not many), had a look of southern untidiness, Nature being left much more to herself than in the north. Large *Camellia* trees were in the borders, and on Christmas-day I gathered a nosegay that would not have disgraced midsummer. The house I inhabited had a terrace in front, with a lawn sloping down to an orchard, over the bloom of which you looked on the sparkling sea. To the left was St. Michael's Mount and Marazion, to the right the fishing village of Newlyn and the sweep of rocks by Mousehole.

But I am leaving the Ferns unnoticed too long, and they will lead me into many a well-remembered spot, and take me amongst fishers and miners, who had always a kindly word for the stranger, that often and often left her the wiser for its speaking; and we cannot say as much for all the conversation we hear in drawing-rooms.—*FILIX-FEMINA*.

### POTATO CULTURE.

I HAVE been much interested, amused, and, I must add, a little confounded, in reading the article in No. 194, the latter feeling brought on by the numerous sorts of Potatoes in *esse* and *posse*. Are we to have as many sorts of Potatoes as of Roses? If so, I, a simple cultivator of a few kinds for the wants of my family, fear a sort of supervening delirium—a Potato distraction—inclining one to leave old favourites and try new kinds. Will you, therefore, Messrs. Editors, allow me to give my forty years' experience, not in a scientific article like that of your correspondent "UPWARDS AND ONWARDS," but merely as the simple annals of a very simple culturist? I may give a few useful hints to those who wish to have a good Potato on their table every week throughout the year; and so I beg of you to pardon my odd ways of cultivation.

About the middle of February I have all the refuse litter and leaves gathered, and mixed with an equal quantity of stable dung. This mixture is then thrown together in a large heap, and as soon as it commences to ferment it is made into a bed 6 feet wide, and 30, 40, or 50 feet long, according as my mixture holds out. After allowing it to heat and settle for about a week some stakes are driven in along each side and the ends, and a three-quarter-inch board a foot wide is placed inside the stakes to support the mould, 1 foot in depth, which is then placed on the bed and levelled. The Potato sets, all greened and with their eyes ready to start, are then planted about 8 inches deep, 1 foot row from row, and 9 inches apart in the rows. I plant them thus thickly because I am rather extravagant, and take some up when very young; but by taking up every alternate row and leaving the others to make a more mature growth, I appease my conscience, which is always at war with extravagance. By the end of February my bed is planted. Its slow fermentation helps on the roots; but it is not powerful enough to resist March frosts, so I cover it with boughs of trees, the "loppings" of the winter, and on them place a covering of litter. This is taken off in April, and light and air admitted to the young shoots, then well above ground. In frosty nights some old mats are thrown over the boughs, or, if the season is mild and early, the boughs are removed, the bed arched over with rods, and mats thrown over them. My situation, or at least my Potato-bed situation, is cold and bleak, yet just as I am getting tired of those flat-flavoured Flukes, in the middle or end of May, my mildly-forced new Potatoes are ready. They soon become ripe, and last well on till the early sorts planted in the open borders are ready.

Formerly—some twenty years since—I used to plant in my hotbed an early sort of round Potato called Early Ten-week. This sort I see was exhibited at the last show by Mr. Moffat in his prize collection of round Potatoes. This, for a round Potato, is very good. I then soon after it was introduced, planted in the same bed the Early Handsworth; but I soon found that this kind, although quite as early as the Ten-week, was hard and indigestible, and I therefore gave up its culture. Of late years, my taste having become more refined, I have planted the Ashleafs (the old sort),

Myatt's Prolific, and the Royal, all of them having the excellent and unique flavour of the type. Last spring I confined myself to the old Ashleaf and the Royal, the latter being quite as early and producing about three times the quantity of the former; and as far as I can judge I shall never again plant round Potatoes, their flavour is so infinitely below that of the finer kinds of Kidney Potatoes.

Is it worth while to tell you how I cultivate my open ground Potatoes? Well, perhaps it is. In the first place, I always plant in ground trenched or stirred with Parkes's fork to 22 inches in depth: if thought to be exhausted a good dressing of thoroughly rotten manure is well mixed with the soil to that depth.

Secondly, I never plant Potatoes in the same ground for two consecutive seasons, but always alternate my crops.

Thirdly, I plant for the most part whole sets of the second or even third size, if the tubers are large, greened by exposure, and their eyes well developed.

Fourthly, Having plenty of space, I afford them much more room than is commonly given, so that each plant is well exposed to the sun and air. My distances are therefore 3 feet apart row from row, and 2 feet apart in the rows. In digging-time it is a positive pleasure to see the beautiful tubers tumbling up twenty-five, thirty, thirty-five, and upwards to each root of such sorts as Royal Ashleaf, and Early Racehorse Kidneys. I ought, however, to add that my soil is very favourable, a deep sandy loam on a dry subsoil; and my climate, within thirty miles of London, also favourable.

Fifthly and lastly ("whilk word I am vara glad to hear," as the young Caledonian said to his mother one day at kirk during the sermon), I never mould up my Potatoes, feeling that to cover the young roots with earth so as to keep out the influences of sun and air can do no good. I hoe between the rows frequently; and if in August any tubers are peeping out owing to the abundant produce some earth is drawn over them with the hoe, and that is all the moulding-up I do.

And now a few words about new sorts of Potatoes, which, like new sorts of Peas, Cabbages, and Broccolis, are by far too numerous. As to Potato-showing, or judging of their qualities by their appearance, it is fudge. If a jury of Potato-lovers could be convened, and have a few specimens of each of the sorts shown for prizes well cooked and then tasted on the spot, some good would probably accrue; but, as I know from experience, the most fair-looking are often the most deficient in flavour—witness those fine-looking Fluke Potatoes now so common in the London eating-houses, very tempting in appearance but flavourless. I may be peculiar in my ideas, but as far as my experience has gone no round Potato should find a place on the table of a gentleman, if the soil and climate will allow of the culture of the fine sorts of Kidney Potatoes. I used to think a few years ago, when Regents and Dalmahoy were the only sorts that escaped the disease, that no better kinds need be wished for; but now that the disease seems to have left us, and the fine kinds of Kidney Potatoes can be had in perfection, I do not suffer a round one to appear on my table. It may, perhaps, assist some of your readers—confounded as they must be by the long array of names—if I say what I have deliberately settled down to.

During the months of June, July, August, September, and October I confine myself to the Ashleafs; and as the Royal and Myatt's Prolific are great bearers and have the true flavour of the old sort, which is a delicate grower and unproductive, I confine myself more especially to the former, which I think will in time be the only sort I shall cultivate for the first crop. Its fault is being too robust; in rich soils its tubers are so large as to put forth protuberances. In November I take to the Lapstone (its other name, "Haigh's Kidney," should be given up), which here is always most delicious. This keeps its flavour, and fine, firm, dry consistence till the middle of March; and then I think a sort called Hudson's King will not disappoint the lover of a good Potato, for, like the Lapstone, it is firm, dry, and excellent. A friend has sent me a seedling Lapstone exactly like its parent, but larger and more productive.

It will be seen from what I have said that three fine kinds of Potatoes carry me through the year, and it is really quite a relief to think that it can be done. It is quite possible that some soils and climates will not allow of these fine

kinds of Kidney Potatoes being grown in quantity; if so, other kinds should be sought for, so as to make the supply as perfect as possible, with as few sorts as possible.

Before I mention other kinds of Kidney Potatoes which have come under my notice, I feel that I ought to say how Potatoes are cooked here. As soon as their skins become set in early autumn, so as to lose the delicacy of "new Potatoes," they are cooked in one of Barlow's steamers, and brought to table "in their jackets." How delicious the Lapstones cooked to-day, flanking the Christmas beef! every one with its jacket unbuttoned showing the yellowish white, firm, yet floury tuber, seeming to say "Eat me," which request was promptly complied with.

There are several really good kinds of early Kidney Potatoes besides the varieties I have noticed. The Early Racehorse is early and a good bearer, but its foliage is crumpled, its vines straggling. It blossoms abundantly, and its flavour is not equal to the Ashleafs. Early Nonsuch and Early May are both early, but not productive. Mona's Pride is a very handsome early Kidney, fit to show for a prize, but in my soil it is deficient in flavour. The Gloucestershire Kidney is early and of good flavour during the summer months. Dawes' or Webb's Nonpareil is a fine prolific late Kidney, but it lacks the firmness and fine flavour of the Lapstone. And then we have the Lemon, the Silver-skinned, and the Prizetaker Kidney Potatoes, about which the less that is said the better. There is no doubt but that in some soils and climates some one or two of these varieties may succeed better than they do with me, but I have come to the conclusion that in a good dry soil like mine three varieties are enough to carry one through the whole year—1st, the Royal Ashleaf, as being as early or earlier than most of them, and of extraordinary productiveness from May till November, and, if not too ripe, even all through the month; 2nd, the Lapstone, from November till March; 3rd, Hudson's King, from March till the end of May. I am not yet quite certain that the Pink Fluke may not come in at the extreme end of the winter Potato season, but I almost fear that its flavour is too much like that of its parent; at any rate there is not the least doubt about the three sorts I have named. They are all productive and of the best possible flavour—what more can be wished for?

I dare not employ a signature so high and significant as your correspondent in No. 194, and so allow me to sign myself—FORWARDS.

#### THE ARBORETUM VERSUS THE PINETUM.

THERE are many indications of the boasted progress of the present age being more in particular directions than partaking of a general character, and, perhaps, it is better that it should be so, for to grasp at too many things at once often ends in failure with all, and when a certain branch of a pursuit has enjoyed its full share of favour, and further advance with it becomes difficult, the public are then readily brought back to the starting point. Thus it often happens that a subject is at first thought too comprehensive, and one of its branches only is pursued, but afterwards the whole is grasped.

Now, gardening is no more exempt from caprice than other pursuits, but rather the contrary, otherwise the present popularity of a few varieties of plants used in the parterre, would not have driven the former occupants almost out of cultivation. My purpose, however, is not now to attack the modern bedding system, and I may remark in passing, that I have some doubts whether those who do abuse it are really in earnest; but there is another and much more important feature in gardening that promised forty years ago, or more, to materially alter the then-existing aspect of affairs, but which very soon afterwards narrowed itself into one of the subsidiary channels, and has continued to run in that with but very little intermission ever since. Certainly it has not done so without good results, as many widely-scattered examples testify, still the original conception has been only followed out in one of its branches.

Before gardening periodicals came into existence, whatever advances were effected by public or private enterprise, were made under great disadvantages, and at great cost as compared with the present day. New plants were less sought

after, not that they were not thought worthy of notice, but simply because they were not known, or if so by name, that was all the information given of them, consequently buyers were unwilling to give the high price demanded whilst such uncertainty existed respecting their merits; and in Loudon's "Gardener's Magazine," supplying knowledge of this kind was one of the points aimed at by the talented conductor, and speedily his enlightened and comprehensive views on the many departments of horticulture, as well as all the sister arts, gave a stimulus to the cause. He being ably seconded by others similarly liberal in disseminating their knowledge, a new era might be said to have dawned on our ancient art, and no doubt if the worthy compiler of the many encyclopædias bearing on rural affairs had lived till the present day, due honours would have been paid to the exertions he had made in the cause. As it is, we can only now do honour to his memory, and calling to mind some of the duties he left us as a legacy, let us see how far we have made progress in executing them.

It must be acknowledged that the writings of the master spirit of his day often gave tokens of his love of the highest and most noble of all cultural pursuits, the planting and management of trees. Alas, that such an exalted pursuit should have resulted in the pecuniary ruin of one so devotedly attached to it; but such is human nature, individual hobbies may be ridden too hard, and no one derive any benefit from them; but in the above case the advantages were given to the public in the costly "Arboretum Britannicum," which is yet a standard work on the subject. But let us see if we have done our part in carrying out what the author suggested elsewhere in this particular department, and it must be confessed that we have fallen short of carrying out what the distinguished author urged about the time of the passing of the Reform Bill, with regard to renovating our woodland scenery by means of fresh introductions. The importance of these he strongly urged on planters for landscape effect, as well as for profitable investment. The word arboretum was then a popular term to designate a mixed plantation, with a fair promise of growing into a vast and magnificent assemblage of objects; but alas for the failure of human enterprises, the comprehensive "arboretum" which promised to bring amongst us families hitherto unknown in cultivation, dwindled down into one of its branches, the pinetum, and the latter has with very little exception usurped the whole of the patronage bestowed on out-door trees. Now, it is far from my purpose to disparage the many noble species of trees belonging to this family that have from time to time been added to our collections during the last forty years, and which yet continue to reach us; but assuredly we may find room for other trees besides Piceas, Pinuses, Thujas, Wellingtonias, Cedars, &c. Assuredly some of the countries whence the many importations received of late have been made, also furnish deciduous trees of more or less value or beauty, and equally entitled to our notice. To limit our whole attention to one particular class is no compliment to our discernment, for when we look at the great beauty of many of our indigenous deciduous trees, we are led to expect that those from other countries also possess merits which only require to be known to be appreciated, and I hope yet to see the time when the rage for Pinuses from all quarters of the globe having exhausted itself, deciduous and other trees and shrubs will be sought after with equal zeal, and people will then wonder how so much worth and beauty could have escaped the notice of the first explorers.

Whilst thus calling attention to the neglect which has of late been the lot of deciduous trees, and unconcern with which new ones are received, I do so in the hope that they will become more fashionable in time. We have seen Tulips, large Gooseberries, the Dahlia, Orchids, Ferns, and Roses have their day, and some of them still retain their popularity, yet there is ample room for many specimens of the most aspiring of all the members of the vegetable world. They attain a larger size, and present forms and outlines more noble than anything else can lay claim to. In our own country no evergreen attains the proportions of the deciduous trees, and these more particularly associate themselves with our everyday notions of beauty, and our daily requirements (and foreign countries enjoying a similar climate must also possess like ornaments)—look at the

Oak, its beauty and utility, and there are more species of this than most people are aware of, and, doubtless, many of them suitable to our climate. Other native trees have kindred species in distant lands only wanting to be introduced to thrive under our comparatively mild winters, while many species, doubtless, exist in the vast extent of mountainous country that fringes the western coasts of both the northern and southern continents of America, as well as many other districts of similar temperature. Deciduous trees existing more numerous in countries where the winters are severe, they will generally be found hardy. Many of these, too, furnish the most lovely flowers; for instance, where is there an exotic plant that excels the Horse Chestnut? while the Apple, Cherry, Hawthorn, and a host of others, have few equals in any class of plants. On the other hand, some present us with a foliage extremely varied, both in form and hue, and some again reserve their beauties until the autumn, when peculiarities in colour are much wanted. Of the latter class the wild Cherry often fades into the most brilliant vermilion.

My purpose, however, just now is not to descant on this subject, but to endeavour to revive that love of Arboriculture which of late has been confined to a single branch, and though I by no means seek to disparage the pinetum, which presents us with so many objects of beauty and interest, it ought not wholly to usurp public patronage. Ornamental as Conifers are, I would simply ask their most enthusiastic admirer what would our English landscape be without deciduous trees? and the accessions to their ranks in the last forty years have been few indeed compared with what has been done in multiplying the evergreen class. I trust, therefore, to hear of new introductions of deciduous trees, and of greater prominence being given to those we already possess; for if fashion can only once be directed in this channel, it will be found that objects of beauty and interest will meet its progress at every step, while the many lovely flowering shrubs we possess of this class will receive accessions to their ranks from other quarters, and deciduous trees and shrubs once more take that place in the vegetable kingdom to which their numbers, magnitude, and general importance fairly entitle them.—J. ROBSON.

## STRAWBERRIES.

I RECEIVED the following from H. Taylor, Esq., of Fencote, Bedale, Yorkshire, an amateur who takes delight in, and much pains with Roses and Strawberries. It may interest the reader, and certainly it bears out what I have said.

He says, "La Constante did not do well here last summer. It was the first that failed for want of water. The fruit was coddled before it was full grown, and it never came to perfection. I have this day dug up a plant, having a suspicion that it did not root freely. My suspicion was verified. The roots do not go down so deep as Strawberry plants usually do, but spread about the plants. This may in some measure account for its being the first to succumb under the heat of a tropical sun. It is handsome and good in colour. I shall give it another year's trial. It stood the winter pretty well. La Constante appears to me delicate in habit, and is very slow to establish itself. My plants look very sickly, and the leaves are a bad colour, what runners were made were very small. I have potted them, and put them into a cold frame for spring planting. None others have required to be so delicately brought up. I fear it will not suit the climate of England."

He then speaks of three other Strawberries, which the reader will remember I have specially recommended.

He says, "Rivers's Eliza withstood the excessive heat of last summer better than any other Strawberry. It yielded abundance of fruit, which was large and good. Empress Eugénie was the next best, and excellent. Eliza and Empress Eugénie run freely, and soon make abundance of roots. The same may be said of Wonderful, which yielded abundance of fruit of good quality, and withstood the excessive drought of last summer in a wonderful manner. These three are remarkably healthy and hardy, are covered with rich dark green foliage, and have not been affected in the slightest degree by the late frosts. The Frogmore Pine held out wonderfully, and yielded large and good fruit. This

variety in my soil does not make many runners. It does not run freely at any time. In my rich, loamy soil it strikes deep at once, and does not make many claws, but what are made go very deep, and are thick in substance."

With the exception of the shy-running of the Frogmore Pines, which ran freely enough here to enable me to make three new plantations tolerably early, the above remarks of Mr. Taylor's coincide with my experience, confirm my statements, and justify my recommendations. They are the best four Strawberries here, and have never failed to gratify me and my visitors. Add to these the Royal Hautbois, Bicton White Pine, and the old Red and White Alpines, and you have a good lot, sufficient for all practical purposes out of doors.—W. F. RADCLIFFE, *Rushton*.

### HEATING A SMALL GREENHOUSE BY FLUES UNDER THE FLOOR.

I HAVE several times alluded to this plan, as one of the simplest and most economical where the trouble of a brick Arnott's stove inside was too much. A lean-to house adjoining a dwelling-house was thus heated, because every other proposed means was too expensive. The house is 17 feet long, 10 feet in width, 12 feet in height at back, and 7 feet in height at front,  $4\frac{1}{2}$  feet of which is glass. One end next the small furnace is solid wall, of the other end more than  $2\frac{1}{2}$  feet is glass. Next the glass end is a flagstone pavement 5 feet in width. The rest of the floor is paved with nine-inch tiles. A small furnace was placed outside the wall low enough for the fire-bars to be from 15 to 18 inches below the bottom of the flue, and as it was not desirable to interfere with the above flagstone, a flow flue from the furnace to the flagstone, and a return from it to the small chimney, in all about 24 feet of flue, were formed. The flues were made near the front, where the walking would be, were from  $4\frac{1}{2}$  to 5 inches wide, and, built of three bricks on bed, were about  $8\frac{1}{2}$  inches deep, both inside measure. Pieces of slate formed the bottom, a thin house-roofing tile was laid over the top, and over that the paving-tiles were bedded in a little mortar, on exactly the same level as the rest of the floor, so that all means of heating are thoroughly concealed, whilst there is the advantage of having in winter a comfortable, dry, warm medium to walk on. No plaster of any kind was used for the flues, except in laying them.

This plan answered extremely well, but severe frosts, as in 1860 and 1861, were just kept out, owing to the glass end, and the distance of the flues from it, in consequence of the flagstone. This season, from altering and enlarging the dwelling-house, the tile floor of this little greenhouse was so much disturbed by scaffold poles, &c., that it became necessary to take up the tiles and lay them afresh. In doing so, as there was still the same objection to meddle with the fine polished flagstones, and as I thought it desirable to have more heat in the house, without rendering any row of tiles very warm, I had another return-flue made of the same size as the others, four walls of  $8\frac{1}{2}$  inches thus forming the three flues, covered as well as the whole of the brickwork by the three nine-inch tiles close to each other. Two bricks on edge would have done for the sides of the flue as well as three on bed, but plenty of bricks were at command, and it was desired to have all firm beneath the feet. Nothing can promise better than this plan.

In making the furnace, I had the whole of it put inside the house, the top fire-brick of the furnace being some 16 inches below the level of the tile-floor. My object was to secure all the heat I possibly could from the small quantity of fuel used. I was disappointed, because the floor immediately above the furnace never became heated. Where the heat rose by an inclined plane to the level of the bottom of the flue, the tiles there became nice and warm, but behind that over the furnace you could feel no heat. I thought this was owing to the draught taking the heat forward, and I recollect stating I would have been nearer my purpose if I had had the legs of the furnace immediately below the floor. I think now I was wrong in such a surmise; on examining this part like the rest, I found the space between the furnace and floor filled chiefly by old bricks placed as open as possible in pigeon-hole fashion. It struck me that this confined air was the cause that kept the heat from the

tiles. I had bricks, &c., laid solid up to the flooring-tiles, and now though this space directly over the furnace does not heat so fast as the flow-flue, it becomes nice and warm, and retains the heat longer than the flue. The furnace and all else is the same, and want of heat in one case, and plenty of heat in another, I attribute to openings and solidity respectively. Thoroughly confined dry air becomes one of the best of non-conductors.—R. FISH.

### VINES AND VINE GROWERS.

THAT there is ample room for more Vines in England I think no one will deny, and I consider that we might every year gain a large amount of money if the resources available for their cultivation were made use of. In a manufacturing country like this there are thousands of steam-engines connected with different kinds of works which are sufficiently far from large towns, and if the waste steam were conveyed into a house in which Vines were planted it would afford sufficient heat to grow them, and well too. For a number of years I had charge of a vineery which was heated by steam from a cotton mill, and I never had better Grapes, and less trouble in looking after insects. There were two double rows of pipes, and at the end of the last return I had a small brass tap, something like those which are put on ordinary half-inch gas-piping. Every spring when the Vines were started I turned the tap partially, and it being an open one allowed the steam to gently come out into the house, and if more vapour was required the tap was fully opened. This saved a deal of syringing and "damping down," in fact the Vines rarely required it. I grew Black Hamburgs at one end of the house, and White Tokays at the other, and had good crops yearly. There is generally plenty of old steam piping laying about works, and if it were put together, and some of our modern cheap houses erected, hundreds might have Grapes without the cost of fire. In houses erected on the principle I have named such pests as red spider are never found if the tap is only turned in the manner I have named.

I made a tour in September principally to see Grapes, and amongst other places I went to Mr. Meredith's Vineyard at Garston, near Liverpool, which, I think, all young gardeners might visit with profit, and many old ones might be disabused of some of their antique notions. Yet the principle on which Mr. Meredith grows his fine bunches and berries is old enough. His system is to some extent like that of growing Gooseberries for shows—namely, few on a plant. I have had quite as fine berries as Mr. Meredith, but nothing like his bunches. Where he had about six bunches on a Vine I had from twenty to twenty-five; both his Vines and mine are about the same age. His fine dry borders this year and good new soil might be imitated with advantage in many places.

The week after visiting Garston I went to see a man who has an old Vine which he allows to bear nearly all the fruit it sets, merely thinning out the berries a little. I had met him several times during the summer, and he invited me to come and see his Vine; "for," he said, "you never saw such a sight in your life" (and I hope I may never see such an one again). He advertised in our local papers, "Such a sight as could not be surpassed! Admission one penny." Well, I went to see his Vine, and the reader may guess my horror, or rather disgust, when I found about 150 bunches of Grapes mostly as green as they were the first day they set, and not a green leaf on the Vine. "I wish I had taken about another hundred bunches off," said the old man. "Taken," I said as soon as I saw them, "I would have taken the dubbing-shears to them if they had been mine." I was partly pleased, and I also pitied him; for he had bragg'd so hard, and told it up and down this part of the country that he would have to teach us gentlemen's gardeners how to grow Grapes. How his Vine will fare next year I cannot say, for the wood was anything but ripe, and there were no leaves. I got him out of a difficulty some years since when he had overloaded his Vine, but it had plenty of good leaves on then; but next year I fancy he will not advertise.

We have a goodly number of cottage gardeners here who have each a Vine, but they all make the mistake of leaving too many bunches. I have seen lots of berries no larger

than Black Currants when they were ripe. I have done what I could to induce them to abandon this practice; but they see a large quantity set, and they have not the heart to cut them off, so all are allowed to ripen together.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

### SWISS GARDENING.

I HAVE been so much occupied of late that I have not been able to keep my promise, which was to give some sketch of continental gardening as compared with our own.

We very often say we are the greatest gardeners of the day, and it is a fact that cannot be denied. I am unable to say much of French gardening, never having resided for any length of time in France; but I affirm that Swiss gardening is far below that of England. This is an opinion founded on personal observation of some years. To begin with, their garden implements are very primitive; their spades are generally a foot longer than ours, though, to be sure, they import largely from England; in every ironmonger's shop one sees "Sheffield wares." But many of the gardeners there, like those here, have a prejudice against anything new, and so the long unwieldy *bêche* remains in favour. Many other tools are, in a like manner, heavy, and it requires no small amount of strength to use them, as I can testify. It would occupy too much time to give a description of all their tools, which, however, are not numerous.

Before drawing comparisons between Swiss and English gardens I ought to remind your readers that the climates are very different, and that this, perhaps, more than anything else influences the style of gardening. It is evident to every one who has spoken with the Swiss country gentlemen that the English style is liked, only the great summer heats prevent its being carried out. The Genevese, however, have an opportunity of seeing a garden laid out as far as possible in our style—that of Sir Robert Peel on the north bank of the lake; but here, as elsewhere, during the summer the lawn is parched and brown, and this distinctive feature in all English gardens is thus lost. Again, the massing and ribbon-border systems, so much in vogue here, cannot be carried out to such perfection there; during the summer heats the flowers droop and die.

As yet I have said nothing about the capital or the energy of the proprietors. As a matter of course, the wealth of the owner of the garden makes some difference in the style in which it is kept; but there are many opulent families in the Canton de Genève and Canton de Vaud whose gardens are shamefully neglected—the few glass houses falling to pieces for want of putty and paint, and the trees and shrubs growing in unheeded confusion, the borders not raked, the weeds undisturbed.

It is much to be regretted that there is no substitute for Dartford gravel to be found in Switzerland. In all the gardens in which I have ever walked, the same grit or small pebbles were the covering for the paths, and they form a disagreeable foothold. When raked over regularly, they look neat, and that is all the praise they merit.

The noble trees, Oaks, Elms, and Thorns, are rare, I might almost say unseen in the gardens, though one frequently sees Chestnut and Mountain Ash trees of fair size. The Spruces, Larches, and some other Conifers are to be met with large and well grown, and were they but properly thinned would be very beautiful.

All this would seem to be saying very little for Swiss gardening, and were it not that I have been able to judge myself, I should be sorry to write so strongly on the subject. But a word on the other side. They grow good fruit. Any one walking along the market-place in the summer months will be astonished both at the quantity and quality of the fruit exhibited for sale. Raspberries, Strawberries, Cherries, &c., are to be bought at a very low figure, as are also Apples, Peaches, Plums, and the like. Melons and Gourds of all sorts are also to be found in abundance, and in the autumn small but sweet little Grapes come in cartloads to the fruit market. Now all these fruits are brought to market by the growers. Very early on the market-day troops of women gaily attired, with the gaudy but picturesque handkerchief tied over the head, come and take their places on the kerb with their one or more baskets ranged in front of them full of fruit of one kind or another. Many get their husbands

to bring them in the common *charrette*, which stands by till the evening, when they all ride home, and give some less fortunate comrade a lift. Some bring flowers—Pelargoniums, Fuchsias, and the like—to be sold each at prices varying from 20 to 30 sous, which shows them to be common plants of no shape or cultivation.

But this letter is getting to be longer than it has any right to be, and so I will finish, hoping at some future period to be allowed to go more into detail as to cultivation, &c.—PATELIN.

### HORTICULTURE A SCHOOL.

THE Rev. Dr. Osgood addressing a public meeting remarked that horticulture is one of the best pursuits to follow for mental culture—that gardening is a school, a workshop and a parlour. As a school it begins with the earth or mineral kingdom, and rises through the vegetable and animal world.

What a school for study is afforded by botanic gardens with their vast collections of trees and plants; but even a small clod of earth is a fit subject for study, exemplifying the truth that "wisdom is oftentimes nearer when we stoop than when we soar." Through all the grades of vegetable life, from the minute microscopic plants to the tall Oaks, there is a world of study and of wisdom. Botany is an interesting study, pursued through the laws of vegetable growth, particularly when illustrated by the familiar plants around us. The gardener studies to get the greatest yield, and he should combine the beautiful with the useful instead of striving to separate them. We may hold up an Apple as a thing of use, and point to a flower as a beautiful object, and these, if not brother and sister, are at least first cousins. Besides a school of learning, the garden should be a school-house of Divine faith.

As a workshop, the garden is one of the very best places to develop bone and muscle. Let a lady take a hoe or rake, and in a few hours every muscle will find its exercise; and the garden is a pleasant place in which to see our wives, our sisters and daughters engaged—the best of all gymnasiums. Flora and Pomona were called by the ancients feminine divinities. Why may we not class gardening among the fine arts? If the cities were left to their own influences, with no migration to or recruits from the country, the race of citizens would become extinct; hence the attempt to bring a portion of the country and locate it in the city. Here, too, we see the relation of landscape gardening to the beautiful arts: for, besides some idea of architecture, the gardener must have an eye for sculpture, and select and plant his trees with reference to their sculptural effect. What fine sky-lines are often produced by a group of trees as seen in the evening. Besides, the gardener is a painter of no mean order, using the colours which nature furnishes, and it is for him to apply them with fitness. How very little, too, it takes to surround one's place with flowers, compared to the sums paid for needless luxuries. Take 300 dols., for instance, which a person can easily eat up at a fashionable restaurant with a few friends, and spend it for Phloxes. For full two months one can enjoy their rich bloom, and they remain for many years. There is poetry, too, in the garden, which none better know than that father of American poetry, William Cullen Bryant, who is both eloquent and poetic over his flowers. Our education would be much more perfect were we to unite the study of gardening with that of books.

The garden is a parlour with pleasing associations. We want something when we come together to unite us socially and bring us into affinity, which the garden is eminently calculated to do. Are not the Strawberry and Grape ministers of civilisation, if not of evangelisation? In enjoying the lovely tints of a flower we exhaust nothing, and rob no one, while at the same time we are brought out of our own selfishness.—(*New York Tribune.*)

ROYAL HORTICULTURAL SOCIETY.—The first of the weekly Saturday Shows was held at South Kensington on the 7th inst., the subject invited being Chinese Primulas. Messrs. E. G. Henderson and Mr. Coysh, gardener to Mrs. Wood, Rugby, had first-class certificates for their collections, the former having their new Fern-leaved kinds, also a handsome

variety of these which was shown separately and received a first-class certificate. An excellent collection came from the Society's Garden at Chiswick. Messrs. A. Henderson sent a collection of flowering and ornamental-foliage plants; Mr. Short, Clewer Park, *Libonia floribunda*, a very ornamental *Correa*-like plant; Mr. Hedges, Wallingford, *Bougainvillea speciosa* in excellent condition; Mr. Coysh, Sericographis Ghiesbreghtiana, *Oncidium divaricatum*, and other flowering plants, also cut blooms of Camellias and Lapageria; and Mr. Smythe, gardener to Lord Sondes, a good specimen plant of *Correa magnifica*. Mr. Ingram, gardener to Her Majesty, had a fine Cayenne Pine and Mushrooms; and Sir Joseph Paxton, M.P., some very good Black Hamburg Grapes, ripened without artificial heat in one of his patent houses. Heat had only been occasionally applied after October to keep out frost and dispel damp. The centre of the table on which this little show was set out was occupied with a fine *Encephalartos Altensteinii*, which is just throwing up three heads for flowering.

### RIPENING OF LATE PEARS.

SEPTEMBER 16th, 1864.—Gathered Marie Louise (A) from a standard in a sheltered corner, the largest on the tree being selected, and stored in a dark, vaulted cellar of a nearly uniform temperature of 52°.

October 8th.—Gathered Marie Louise (B) from same tree, and stored them similarly. Fruit still hard and unripe, but nearly one-half larger than A, which are to-day quite ripe and melting.

October 24th.—A over-ripe and decaying; B still hard and not at all melting.

November 9th.—B slightly over-ripe.

November 29th.—Gathered Marie Louise from same tree hard and unripe. Stored a portion (C) in a dark cellar as before, another portion (D) in the open air, protected overhead from rain by a glass covering, but freely open to ventilation laterally, and fully exposed to sunshine.

December 15th.—C over-ripe and decaying.

December 25th.—D part over-ripe and decaying, part ripe and melting.

The above noted in my pomological diary, may contain a fact or two in furtherance of the inquiry started by "T. G." (page 512). Early Pears, if I mistake not, are retarded in their ripening by premature gathering, but the rule would seem to be otherwise with later sorts, for by successive gatherings it would appear that Marie Louise from the same tree may be had fit for table use for a period of upwards of eight weeks. At all the dates given the fruit was fully entitled to be called delicious, that which was ripened slowly under glass being quite equal to the other lots forwarded more rapidly in the higher temperature of the cellar.

It would be an interesting subject of inquiry whether we are not altogether wrong in excluding the light from late-ripening fruit. Light is, indeed, pre-eminently the great ripening agent in nature, and though unquestionably a low temperature and darkness will retard the process, still when the desired period of perfection approaches we are wrong, I think, in not employing light as well as heat to further our object. The fruit D rested on a plate of glass elevated about 2 inches above the surface of the ground, the protecting glass overhead being some 6 or 8 inches higher. The wind played freely over the fruit, which was, notwithstanding, plump and free from shrivelling like that from the cellar. For very late Pears I would suggest the Waltonian case as the best of all means that could be employed for ripening them.

Will "T. G." and a few others join with me in experiments in this direction? Light in its relations to vegetation has not received its due share of attention from horticulturists, who seem to overlook the fact that Nature always increases heat and light simultaneously. On another point also there is wanted a collection of facts to base sound practice upon, I mean the periods of increase in size of some of the commoner varieties of fruit. Will some of the many interested in pomology devote a few minutes once a week to registering in the coming season the length from the junction of the stalk to the eye, and the greatest diameter perpendicular to the axis of growth, of the Jargonelle, Marie Louise, Louise Bonne, and a few others? The immense increase in size of the Marie Louise (B) in the short interval of twenty-

one days, and after a period when I had supposed the fruit had reached its full size, suggests the means of ascertaining the period, differing in different fruits, when moisture should cease to be applied to the soil, and the roots be to some extent carefully protected from rain. And this is only one of many points in the same connection worth thinking about.

—FRUIT EATER.

### SKELETONISING LEAVES.

"WHAT are you doing so mysteriously, Mary," asked Marion, "with that pan of very dirty-looking water?"

"I am trying to make skeleton leaves," she replied.

"Oh, I remember, Mr. Hope said something about our trying that; but it has been forgotten, for we have found so very much to do this summer. I never felt so busy in my life."

"It is too late in the year, now," said Mary.

"Then why are you trying, if it is too late?"

"Oh I began more than six weeks ago, and this is only part of the method."

"Do tell us all about it," asked Margaret, "and then we can try next year."

"I shall be very glad to tell you, and show you all I can. I procured this large earthen pan and put into it a quantity of leaves. At first I thought any kind of leaves would do, but Mr. Sinclair told me that those of the Oak, Chestnut, Elm, Sycamore, and Walnut, which I thought would all make pretty skeletons, had so much resin in them that they would not decay themselves, and they would also prevent other leaves that were mixed with them decaying, because the resinous quality in them would affect the water; so I had to throw all those away, and lost some time. He then advised me as to the choice of leaves, and seed-vessels also, which must be gathered just before the seed is ripe. He wrote me out a list of leaves, and Harry and I gathered a quantity of those we could procure."

"Do tell us what they were."

"The leaves we gathered were those of the Poplar, Lime, Tulip Tree, the Apple, Pear, Apricot, Orange, Lemon, Box, Ivy, Holly, Magnolia, and Passion Flower. Then we added the calyxes of several plants, as the Nicandra, Campanula, Dictamnus, Mallow, Poppy, and several more; and also a few stalks of Cabbage, Flax, Hemp, and Stinging-nettle. We procured a good quantity of each, as that helps the decay."

"What did you do then?"

"We put them all into the pan, and poured a quantity of boiling soft water over them."

"Why boiling water?"

"Mr. Sinclair told us it would destroy the vitality, as he called it, and hasten the process. Then gardener put the pan on the top of this low out-house to be out of the way of the fowls, and that it might be exposed to the sun and rain."

"But did not the water dry up soon?"

"No, the rain filled the pan again several times; and Harry used to get up once a-week and stir it. Now gardener has taken it down for me, as I believe in six weeks some of the leaves are ready."

"And what are you going to do now? They look so messy and discoloured that I cannot imagine anything pretty being made of them."

"I will try one," and Mary put her hand into the discoloured water and drew out a Tulip-Tree leaf, which was already showing some of its fibrous formation, the green part having decayed and partly fallen away into the water; this leaf she held carefully by the stalk under the tap of the butt. The stream of water quickly washed away all the remaining fleshy decayed green part, and left the leaf a skeleton, to the great delight of the girls; then placing it carefully in some clean water, Mary tried another leaf with the same result. Now and then one gave them more trouble, being so tender that the force of the water broke it all to pieces; then Mary remembered Mr. Sinclair had told her that in this case she should lay the leaf on a little piece of board, and holding the two together between her finger and thumb, the stream of water would run over and through the leaf without breaking it. Some they found, even after this process, had little bits of green substance which would not come away; when it would not yield at all, even after being

carefully rubbed with the finger, they returned that leaf to the pan to be soaked some days, or a week longer. The process interested and amused them very much, and they had a good quantity of tolerable specimens thoroughly cleared of all the fleshy part, and were beginning to think of leaving off, when Herbert and Harry returned from their morning studies and joined them. Herbert, who knew what Mary was going to do that morning, had asked Mr. Sinclair what was to be done to bleach the leaves, and had been told what to procure at the chemist's in the village on his way home, and how he was to manage the process.

They now returned to the house, and went to the boys' play-room, anxious to see the whole. Herbert procured a hat-box, and tying some of the skeleton leaves to strings across the top, and placing some sulphur, which he set on fire, in a cup at the bottom, he shut down the lid and left it closed for the sulphur to bleach the leaves, which it would do gradually. On some of them he tried another experiment; he had procured a little diluted chloride of lime, and also chloride of soda; these he poured into separate shallow vessels, and immersed some of the leaves in each for a few minutes, and the party had the great pleasure of seeing the skeletons gradually lose their dirty appearance and become very white.—(*Churchman's Family Magazine.*)

### CULTIVATION OF THE MELON.

(Continued from page 495.)

It sometimes happens that Melon plants are required with a stem a foot or more high, in order to bring their bearing shoots to the light. In this case the plants are prepared by pinching out the leader at the second leaf, as in *fig. 17*, by which a shoot is obtained that is better calculated to afford fruit from the side-shoots than were the

Fig. 21.

plant allowed to grow up without stopping, as shown in *fig. 21*, for judicious stopping promotes fertility by rendering parts active which would otherwise remain dormant.

The plant having been stopped, two shoots will arise from the axils of the leaves; the stronger should be retained and trained to a small stick, the other being cut clean out, and, as the shoot grows, at every leaf a tiny knob will show itself, which if left will elongate into a shoot. When of sufficient size, and that is when first seen, the knobs or shoots should be taken out with a pin or the point of a small knife, letting the leaf remain, for if removed, as in

Fig. 22.

*fig. 22*, the sap will exude from the cut footstalk and several ulcers may consequently be formed at the stem. The leaves which have been left, having no shoots springing from their axils, will die off gradually, and the sap they elaborate before they do so will strengthen the stem of the plant, and so much the more vigour will be thrown into the leading shoot. This will be apparent in *fig. 23*, in which all the side shoots are taken out of the axils of the leaves, but the leaves retained up to *o*.

Fig. 23.

pinched out. This will cause laterals to be emitted, there being some already at the base of the principal shoots which

must not be stopped but trained-in at their full length. These laterals will show fruit at the first, second, or third leaf, and after the flowers have been duly impregnated the laterals are stopped to three joints if there is no fruit on them, and if there is, to the joint above the fruit, let it be where it may; but the plant should not be stopped until after fertilisation has taken place.

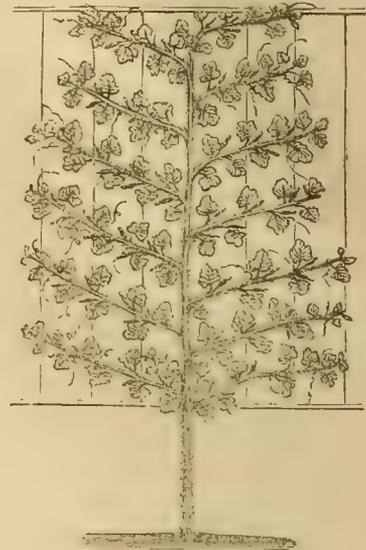

Fig. 24.

Prior to stopping, if the plant have one principal shoot, it will appear as shown in *fig. 24*, and when stopped the laterals will appear, as shown in *fig. 25*, *p p p*. After setting or stopping, sub-laterals will appear from the bases of the

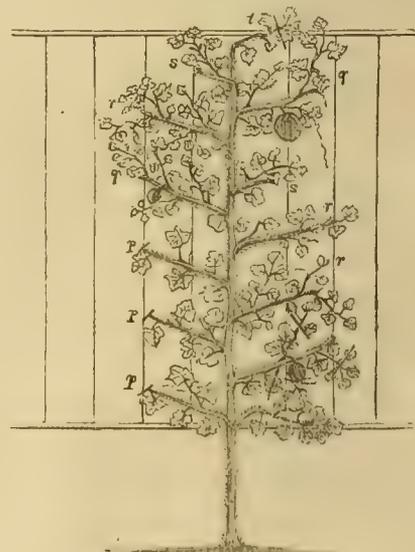

Fig. 25.

leaves retained, some with fruit at their base, *fig. 25*, *q q*, and others without, *r r r*. From a week to ten days after the fruit has set and is swelling freely, the sub-laterals will be of sufficient size to be stopped, or, if not, the right time to stop them is when they have grown to the extent of three leaves. Laterals not producing fruit may have the two upper sub-laterals removed, they will then appear as shown in *s*, and the one left be stopped a week afterwards to two or three joints, *t*. Those laterals producing fruit should have the sub-laterals below the fruit stopped to one joint, that by the fruit to three, and that above the fruit to three

or four, presuming the fruit to be at the second joint; but if it is at the third joint, the first and second sub-laterals should be shortened to one eye each, and that above the fruit to three joints. After this all the shoots from whatever part they arise should be cut out if they crowd the principal leaves, or be stopped to one leaf as fast as they present themselves, until the fruit is ripe. If the fruit does not set on the laterals, the plant is to be treated in the same manner as described in *fig. 20*, and fruit obtained, on the sub-laterals as therein shown.

I have now gone through the training of Melons with a minuteness which I hope will make the subject plain even to the uninitiated, and I believe I am the first who has offered illustrations of Melon training, and am the second to give the training of the Melon reduced to a system. Our able and worthy coadjutor, Mr. Fish, was the first to treat of the training of Melons on a system, all others merely offering vague recommendations to thin here, stop there, and hence the Melon in the hands of most is liable to failure, either from the plants not setting their fruit, and its cracking before ripe, and not uncommonly the plants will die from disease or other cause before a crop ripens.

Mr. Fish's mode of training is so simple and yet so satisfactory in its results, that I do not hesitate to repeat it here, though it has appeared from time to time in this Journal. Mr. Fish thus describes his practice:—"As soon as the Melon plant has made three or four leaves or so, you nip out its point. This in a short time will cause a shoot to come from the axil of each leaf. These will be the secondary shoots. As soon as we can see them we pick out all the incipient shoots except two (when two shoots are required), using the point of a budding-knife or penknife for the purpose. One of the secondary shoots as it grows is trained to the back and the other to the front, or, if it please the practitioner better, a little advantage is gained by training both shoots of that plant to the back, and both shoots of the next plant to the front. As the shoot grows, every large leaf formed at every joint is carefully kept, but every young shoot forming at its axil is nipped out with the penknife again, so that these secondary shoots shall be clear of side or tertiary shoots for from 15 to 18 inches from the main primary stem of the plant. After that the secondary shoot is allowed to grow without any side pinching; and when it reaches within 6 inches or so of the sides of the frame, back and front, an inch or so is nipped off its point, at any rate manage it so that when stopped there will be six or seven joints at the ends of the secondary shoots, from which the young tertiary shoots in the axils of the leaves have not been extracted. After the points of the secondary shoots are stopped, these tertiary shoots will grow with great rapidity, and most of them will show fruit at the first joint, and then being nipped at the joint above the fruit there will generally be strength enough in the plant to set them swelling kindly at once." If the secondary shoots do not show fruit at their first or second joint stop, that they may throw out fresh shoots, which is necessary with some shy kinds in order to get them to show and set their fruit; "but in general better crops and more regular ones are secured, than by the plan of early stopping and getting the space filled with shoots and twigs before a fruit can be induced to set."

"In pits when grown on trellises, or when so grown from pots, we prefer taking the first primary shoot to the height of the trellis, stopping there; selecting the secondary shoots and treating the same as above."

Mr. Fish thus points out the merits of the system—"It is of importance to get as many blossoms to open about the same time as is desirable, so as to insure their simultaneous setting."

G. ABBEY.

(To be continued.)

### IONOPSIS PANICULATA CULTURE.

*Ionopsis paniculata* degenerates with me. I bought a specimen two years ago with two spikes of lovely bloom on it. The next season two spikes were produced, but the buds never properly opened. Last season one spike only appeared, which refused to expand in like manner. The flowers come to the very verge of opening, and then they

wither. Does the plant require any peculiar conditions of heat, moisture, shade? Is it considered difficult to grow?

I have *Gloriosa Plantii*, Is *Gloriosa superba* so much superior to it as to make it worth while to get this in addition to the former?—ORCHIDOPHILUS.

[We have made the inquiries needed of Mr. Williams, of the Holloway Nurseries, and this is his reply:—"The reason of *Ionopsis* degenerating, I should say, is through flowering this plant too freely before it was well established. The plant, I suspect, shrivelled at the time of showing flower, which is often the case with these small Orchids. The best remedy is, not to let them flower until the plant is well established upon the block by emitting plenty of good roots. This will insure good bloom. *Ionopsis paniculata* is a difficult plant to establish. There are a few plants that have succeeded well in this country, but not many. It being such a free-flowering plant causes it to shrivel, and when that happens it will most likely die.

The treatment we have found best is to place it on a block of wood with a little live sphagnum moss, and a good supply of moisture. In fact, when growing always keep it moist at the roots, and not in too much heat at any time—55° to 60° in the winter, and 70° to 80° during summer. Keep it shaded for it does not like the sun.

*Gloriosa superba* is superior to *G. Plantii*.]

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

PROCEED with the routine of trenching, draining, and all ground alterations suggested in previous calendars. Old gardens are often crowded with fruit trees. As light and air are more required for the important products of the garden than shade, take measures for removing all trees objectionable in this respect. *Beans*, if former directions have been carried out in making sowings of Peas and Mazagan Beans, a sowing of the Longpod Beans will be found to produce an excellent succession. They should be sown 4 feet apart. A second sowing may also be made of the double-blossomed Early Frame Peas. This variety of Pea is of greater service and better in quality than many of the newer kinds, it deserves a place in all gardens where choice vegetables are esteemed, and to grow them to perfection they should be allowed 5 feet between the rows. As severe weather, though long delayed, may yet be near, a few hints on the best means of preserving ice will be opportune. When filling the ice-house, it is not requisite that the ice be very thick, on the contrary, it is much better thin, if a sufficient quantity can be obtained. Before commencing to fill the old straw should be taken out, and fresh substituted for it; as the house is filled it should be placed round the walls a foot thick; as the ice is brought to the door it should be well broken, and then thrown into the house, when it should be beaten to powder, as on this depends its keeping well. On every layer of about a foot thick pour some boiling water which will cause the ice to congeal into one solid mass. It is by inattention to this particular, that there are so many complaints of houses not keeping ice well. After the house is completely filled, close the passage with straw; of course there will be a vacuity between the ice and the roof of the house, this must also be filled with straw.

#### FRUIT GARDEN.

If any transplanting of fruit trees has yet to be done, it should be seen to as soon as possible, as the weather is still favourable for such work, also see to getting ground intended to be planted with young trees prepared, and spare no pains or expense to have this properly done. Make sure of thorough drainage, and where all the subsoil is of one kind, this should be removed, replacing it with some good fresh loam.

#### FLOWER GARDEN.

Alterations should be proceeded with vigorously if they are in hand, if they include the removal of trees especially. Attend to the edgings of walks and beds, reset flints, and repair Box-edgings, rake worm casts from your lawns with a daisy-rake; where the grass is killed under trees in the pleasure ground, rake in strong manure, or apply manure water, to prepare the soil for grass seeds to be sown late in the season. Where any of the beds or borders require a

dressing of fresh soil, this should be provided. Fresh soil is, in most cases, preferable as a dressing for flower-beds to manure, which is apt to cause too luxuriant a growth for a first-rate display of flowers. On soils that are naturally poor, however, and where neither fresh mould nor decayed leaves can be had, a moderate dressing of well-rotted farmyard manure will be useful; but this should be well mixed with the mould to the full depth of the bed, and not carelessly turned in, and left in lumps near the surface, for in this case a gross habit of growth would be promoted early in the season, and as the principal part of the roots would be near the surface in the summer, the plants would soon feel the effects of dry weather, whereas if the manure is well incorporated with the soil to the depth of about 18 inches, no ordinary amount of dry weather will injure the plants after they are once fairly established. Pink and Pansy-beds should be examined, and all plants that are loose carefully fastened. The same remark applies to seedling Auriculas and Polyanthuses. With respect to Ranunculuses lose no time in making what purchases may be necessary. Anticipating the approach of winter, with its usual inclement attributes, cautions have been given and directions repeated, for the protection of plants liable to be affected by frost. The exercise of forethought is demanded of a gardener in every operation he undertakes. To avert by precautionary measures the evil consequences that result from unfavourable circumstances of climate, is a duty that our climate renders imperative.

#### GREENHOUSE AND CONSERVATORY.

While the weather continues fine and mild allow the plants in these structures the full benefit of it, by the admission of abundance of air during the day. Fumigate on the first appearance of green fly. See that the worms do not remain in quiet possession of their pot lodgings, and remedy any defects that exist in the drainage of plants in pots. The principal object should be to guard against plants commencing growth at this unfavourable time of the year, and to keep in check damp and mildew, which the weather we are now experiencing is likely to induce, more especially in the case of plants that are at all delicate, and such as have imperfectly ripened their wood. To assist in promoting a free circulation of air through plant-houses, some of the inferior duplicates might now be removed to spare vineries or other quarters, for anything approaching a crowded state among plants will be sure to cause at least a partial loss of foliage.

#### STOVE.

A little advance in temperature may be permitted here at present. Wait for an increase of light, without which all applications of heat and moisture will be vain. Let 60° without sun be the maximum. Some of the Orchids—such as the *Lælias* and *Cattleyas* will commence rooting, let them have attention and encouragement. The *Cymbidium sinense* is a most useful plant for the drawing-room, the scent is most delicious. A thorough baiting for snails and vermin should take place previous to potting.

#### FORCING-PIT.

Keep up a regular succession throughout the season by bringing forward stock as wanted. Roses, both dwarf and standard, Honeysuckles, hybrid Rhododendrons, and Azaleas, with a host of other things, in addition to the usual occupants of the houses, will enable cultivators to make a brilliant show. Hyacinths, Narcissus, Tulips, Lily of the Valley, and other plants of the above class must be duly forwarded as wanted. A day heat of 60° or 65° will suffice at present, sinking at night to 50° or 55°. Fumigate occasionally to keep down green fly.—W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

The weather has been very variable. Within a few hours we have had frost, thaw, snow, and mild weather following each other, and now, on Thursday evening as we write, with a rising barometer, we have one of the most telling rains of the season, which will rejoice many in this neighbourhood. Work was regulated very much accordingly. Dung and decomposed material from the rubbish-heap, which we are

forced by necessity to make the most of, were wheeled on frosty mornings and one frosty day on quarters of the kitchen garden and on to flower-beds, previously ridged up. Ground was also turned up and ridged, which we consider to be a good plan with all ground that is at all stiff with a clay bottom. This turning and loosening the subsoil, and just getting up a little of it to mix with the surface soil, we consider to be a fine thing for the generality of culinary and flower-garden plants. By such means there is little chance of exhausting the ground, or making it sick of cropping, if rotation of crops is duly attended to.

In *trenching* or *ridging* care should be taken to move and break all the soil, except that which forms the ridge, as the frost and the influence of the atmosphere will generally do that well enough. We have known large lumps and widths of soil tumbled into the bottom of a trench, and also good spaces left in the middle untouched, just as if the object had been to follow the lazy-bed system represented at page 6. If the ground is turned up when dry, and also levelled down again when dry, there will be no trouble from excess of moisture in deep regularly-stirred land, whilst the very depth will also secure from overdryness in drought. When men dig, or trench, or ridge in slushy soil, or turn into a trench with mattocks and levers great lumps and breadths of frozen earth, it would be more economical policy to pay them to let the work alone, if there were nothing else to do. Just let any one turn down such frosted earth, and note how long it is before the heat of spring brings it to the general temperature. If people will pick up such frosted ground we would advise leaving the huge blocks on the surface piled as openly as possible; then the toughest soil would be pulverised. The pulverising of such blocks, when no better job can be obtained, is a very different thing from turning frozen lumps into a trench, and placing unfrozen soil over them.

Chalk obtained from sinking a well we had spread out, so that the lumps might be well cracked by the frost, and then threw it along the ground, ridged up, intended for Carrots next season; and if there is much more frost the lumps of chalk will be well powdered before sowing-time. For all stiff land chalk or other calcareous material operates very beneficially, and is especially valuable in old gardens for Carrots and plants with similar roots. It makes such land opener and drier. In the case of light sandy soil the chalk renders the land more retentive of moisture. Even in heavy land it is amazing how soon chalk goes to the bottom of the stirred soil. Many years ago we dressed part of the garden with chalk, but we lost all traces of it for a number of years, until we trenched it up deeply, raising even a little of the subsoil last year for Carrots, and from the bottom we returned to the top some of the chalk applied long ago. It is a great advantage when from sinking a pit or well the subsoil can be used to ameliorate the texture of the surface soil.

Routine work has chiefly been confined to protecting and uncovering Asparagus, Radishes, and Cauliflower, the heads of the latter coming in for use being much attacked by mite; sowing Peas in pots; planting Potatoes in pots; putting up a dung-bed, but chiefly tree leaves, for raising young Cucumbers, &c., to succeed those now in the pit; planting Kidney Beans, and soiling another piece of a Mushroom-bed. Celery has had the heads uncovered in fine days. Took up also a little more Sea-kale and Rhubarb for the Mushroom-house. In wet weather cleaned pots, made and repaired straw covers, and cut up wood under cover for furnaces.

#### FRUIT GARDEN.

Pruned and nailed in suitable weather. Protected the roots of trees in pots from the frost, placing them close together on purpose. Looked over Grapes, some of which are now getting the worse for wear. Watered Strawberry-pots in orchard-house, as, if the roots become too dry, the bud is apt to suffer. Gave also a little water to pots in small Vine-pit. Put some hot leaves on a part of a Vine-border. Prepared for washing trees in orchard-house, and as soon as practicable will thin and prune trees in small orchard. As soon as possible will wash low standards with soot, lime, sulphur, and clay, to keep the birds from the buds, and to smother all insects' eggs.

The ground is now in capital order for planting. The rains we have had will make it just moist enough; before it

came it was still over-dry. In forcing, no time should be lost in starting Vine-buds that are intended to fruit next season. A hotbed is the best place for them. An outline of treatment was given the other week. To have Melons in the end of April and beginning of May, a few seeds should be sown in a sweet hotbed. The seeds should be sown thinly, and protected from mice. When this protection can be given we prefer sowing two or three seeds in a small pot, the smallest above a thumb size, and then leave the best one to grow, allowing only one plant to a pot, and giving it a larger pot as it needs it, until planting-out time. In such a hotbed Melons when young generally do better than when grown in houses or pits heated by hot water. Cucumbers may be raised anywhere, but young Melon plants dearly like the smell of the hotbed. When we had plenty of manure we have gathered as fine Melons in the first week in May from wooden frames, as we have ever done with the assistance of hot water. Of course, there was a considerable amount of labour in banking up fresh material round the boxes, and we would rather say nothing of the quantity of material we used, which all came in useful in the spring and winter months.

We have no objection, quite the reverse, to hot-water pipes, even a flue, or a brick or iron stove, but we do like to see a range of old-fashioned dung-beds, as it tells us that the means will be at hand for securing succulent Cabbages and Cauliflowers, and sweet, crisp Celery. Some of us were so enraptured with hot water, as to despise the old useful hotbeds, and we may wish and wish again, and wish in vain, for a good dressing for a Cauliflower quarter. The young gardener will act wisely in securing the means for these hotbeds, never forgetting that a part of their usefulness is only beginning when they have served the purpose for which they were first made.

Figs to be ripe in May should now be started with a temperature of 45°, increasing gradually in a month to 55°, sprinkling the shoots gently in sunny days. Peaches may also be started at the same temperature, keeping the house rather moist until the flowers begin to open, raising the temperature gradually from 45° to 55°, and not allowing it to rise above that limit at night by artificial heat, until the fruit is set. Vines, start in a similar temperature, increasing in three weeks to 60°, and not going above that with artificial heat until all the buds are showing nicely. In all these cases, provided air is given early, there may be a rise of from 10° to 15° or 20° by sun heat, and the shutting up of the houses early so as to enclose a good amount of sun heat, will be better for the plants, than more fire heat, or more air. Vines in pots will do best when started in a mild bottom heat. If put into a bed at first with fresh fermenting horsedung, and care taken that the roots are not too much excited, the fumes from the dung will render all washing and painting of the plants unnecessary; but these fumes must be as sweet as to suit a young Cucumber plant before the buds break, or they will be injured to a certainty. We have had dormant Vines for three weeks in such a steaming atmosphere from horsedung, that you could not see your finger before you at an arm's length from the eye, but the steam and vapours were quite sweet before the buds broke, and they broke all the stronger in consequence. Than such a steaming, not in winter, but in spring and autumn, we have found nothing better for eradicating scale from Pine plants; but if bug make its appearance, washing must be resorted to in addition, as the woolly covering protects them, and if at all distressed, they would find their way to the roots, where nothing could be done with them except shaking away all the earth, and carefully washing the roots.

#### ORNAMENTAL DEPARTMENT.

*Mahonia aquifolia*.—Prepared for planting for cover and timber, as it is quite possible to secure both objects. Our chief object, however, for mentioning this is for ascertaining from the experience of our coadjutors and readers how the Mahonia or Evergreen Berberry withstands the attacks of hares and rabbits. We have ourselves seen great lots of this plant quite untouched, when other trees and shrubs, except Rhododendrons, were much nibbled and barked. We have, therefore, recommended it largely to gentlemen for undergrowth; but two years ago we planted a little piece for undercover, the plants being if anything rather small,

and that may have been the cause of the disaster, but not a single plant was allowed to grow. After being repeatedly nipped over, and pushing out again from the bottom, the young shoots were served in the same way. We dressed them with material not very pleasant, we thought, to any eating thing; but notwithstanding bad taste and bad smell, away the shoots went as soon as they were formed. It might have been all in sport; for though cut over to the ground we do not think that much of the plant was eaten. At any rate, every plant was cleared, and we do not suppose that it would have been possible to have kept them, unless we had presented something to the destroyers more gratifying to their palates or more tickling to their propensities for fun. Thinking of planting on a larger scale, we would be glad to know the experience of others in this matter, as the above is almost the only unfortunate result that has come under our observation.

*Planting and Transplanting Ornamental Trees and Shrubs.*—These may now be planted and transplanted with better chances of succeeding in many places than if the work had been done earlier in the winter where there was a scarcity of water, and where the ground was too dry to permit of planting being done to any great extent without watering. Now the ground is just moist enough from showers to render much watering unnecessary. In transplanting large trees and shrubs two plans may be followed. By the first, the plant is cut round, say 3 feet from the bole, a year or two years before removal, and the tap-root also cut. This causes a mat of fresh roots to be made all round the ball, and if the ball is moved carefully the transplanted tree can scarcely fail to grow well. By the other plan, a ball, though useful, is of less consequence, but it is of consequence to trace out and secure as many of the roots as possible, and as long as possible, and then these are to be spread out nicely, and secured in the fresh soil. In either case the too general custom of inundating such roots with great quantities of water is an injudicious one, as, instead of assisting the main roots to make fresh rootlets, the cold produced by continuous evaporation from the soil prevents fresh rootlets being formed, even when the sun, striking upon the swelling buds, makes a demand on root-action which from cold they are unable to supply. If in planting such roots are merely damped, or are dipped a few minutes in water, and then the naturally dampish earth firmed well about them, the roots as well as the top of the tree will partake of the stimulus of increasing heat, and fresh rootlets will be freely formed. Whilst they are merely forming, instead of deluging the soil with cold water, if the favourite tree or shrub shows any sign of distress, it would be better to sprinkle the top with water, or even give a little shade. In particular cases the ground might be mulched in cold weather, and at night, and uncovered in sunny days to let the ground become warm. In planting out favourite trees and shrubs from pots, the earth should be mostly shaken away, and the roots nicely spread out, and packed, and very moderately watered, keeping dry earth on the surface to prevent rapid evaporation. Such plants should also be securely staked, placing the bottom of the stake some inches from the bole of the plant. If the plant is at all tender, or the place exposed, a few evergreen branches fixed securely round it, but at a safe distance for the first winter at least, will be a great advantage. In poor, thin soils, such trees should be placed on hillocks, and the diameter of these may be increased as the roots extend.

As to houses, pits, air giving, &c., see previous weeks.—R. F.

#### TRADE CATALOGUES RECEIVED.

S. Ponsford & Son, Loughborough Park Nurseries, Brixton, Surrey.—*Select Retail Catalogue of Kitchen Garden and Flower Seeds.*

P. Robertson & Co., 33, St. Andrew Square, and Trinity Nursery, Edinburgh.—*Sower's Guide, a Descriptive Catalogue of Kitchen Garden, Flower, and Agricultural Seeds; Selection of Gladioli and other Bulbs.*

Carter & Co., 237, 238, & 261, High Holborn.—*Gardener's and Farmer's Vade Mecum. Part I., Flower Seeds and Plants. Part II., Vegetable and Agricultural Seeds.*

COVENT GARDEN MARKET.—JANUARY 7.

The supply, both of fruit and vegetables, continues good, and that of the rougher kinds of both is still heavy. Apples and Pears consist of the same varieties as mentioned in previous reports, and Grapes and Pines are sufficient for the demand. Importations of salads from abroad are now frequent, and comprise Cabbage Lettuce, Endive, and Barbe de Capucin. Other forced vegetables consist of Kidney Beans, Sea-kale, Asparagus, and Potatoes, the last of which may be had for 2s. 6d. per pound. The Potato trade is still heavy and supplies large.

TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

MUSCAT HAMBURGH VINE (*Lincoln*).—We have this on its own roots planted out in an outside border, and this year fully one half the berries shanked. It does very fairly planted in an inside border; but it is even then more liable to shank than any Grape we know. Grafted on the Black Hamburgh it is not liable to shank, and unless it be so grafted, we do not recommend it for planting in an outside border; and we think you will be acting wisely to plant Black Hamburgh Vines, and inarch the Muscat Hamburgs upon them after both have started into growth. (*J. S. A.*).—Write to Mr. Pearson, nurseryman, Chilwell, near Nottingham, who has grafted this variety largely on the Black Hamburgh, and who has a large stock of plants for sale. You cannot grow it successfully on its own roots.

LIMEWASH FOR CURRANT BUSHES.—PEAR LEAVES SPOTTED.—STRIKING EVERGREENS (*Bank Clerk*).—Mix equal quantities of lime, sulphur, soot, and soft soap with sufficient tobacco water to bring the mixture to the consistency of thick paint, and paint the trees from the bottom upwards, brushing the mixture into every hole and crevice. Do this before the buds begin to swell, from November to February being the best time. The Pear leaves are browned through the dryness of the ground, your limestones oil not probably being suitable for the stock the trees are worked upon. Your remedy is to manure well with coal manure, as cowdung, and to mulch the surface in summer in order to diminish evaporation. Cuttings of evergreens are best put in about the end of September or beginning of October.

TREMANDRA CUTTING DOWN.—REPOTTING CRASSULA COCCINEA (*H. E.*).—Repot the Tremandra in March, and cut it down a month afterwards, leaving a few inches of the young wood. The Crassula may be potted at the same time, in a compost of equal parts of turfy peat, turfy loam, and leaf mould, with a free admixture of sand, and pieces of charcoal about the size of a hazel nut, in quantity equal to about one-sixth of the whole.

SINKING HOTBEDS (*Humdrum*).—See "Doings of the Last Week." There is the advantage that the part sunk is not exposed to the cold winds; and if the sun can reach the glass as well there is no disadvantage whatever, provided no water lodges in the hole, and linings can be given if necessary.

SALVIA NEMOROSA—EVERGREENS (*B. B.*).—We do not know where you could purchase plants of *Salvia nemorosa*, which is so valuable for bees. Perhaps some of our correspondents can furnish the information. If you send your address we may be able to put you in the way of procuring a few plants. *Colletia bictonenis*, *Cotoneaster Simonsii*, *Chamaebatia foliosa*, *Berberis Darwinii*, *Euonymus japonicus aureo-variegatus*, *marginatus*, and *ovatus aureo-variegatus*; *Aralia Sieboldi*, *Aucuba japonica vera*, *Cerasus ligusticum myrtifolius*, and the variegated form of the common Laurel; *Ligustrum glabrum*, and its variety *aureo-variegatum*; *L. japonicum*, and its gold-leaved variety; *Rhaphiolepis ovata*, and *Skimmia japonica*. In addition to these there is a great variety of Hollies, Box, and other evergreens, as *Laurustinus*, *Berberis*, *Arbutus*, *Cotoneaster*, and many others. The beautiful varieties of *Osmanthus ilicifolius* are new and very fine.

RADISHES FORCING.—LAWN GRASS SOWING (*J. A. H. S.*).—You may sow Radishes in any light rich soil, either on a slight or moderate hotbed. Give plenty of air and all the light possible, a temperature of from 50° to 65°, and in watering let the water be of the same temperature as the air of the frame. Cover the sashes at night and in frosty weather. You may sow grass seeds in March or April whenever the ground is in good condition; but the end of March or early in April is generally the most favourable time. A good lawn mixture should contain *Trifolium repens*, the White or Dutch Clover, also the Small Yellow Clover, *Trifolium minus*; but without knowing the nature of the soil and situation it is impossible to say what the proportions should be. You had better consult some of the seedsmen who advertise lawn mixtures in our columns, and you will probably be able to obtain a suitable mixture at a cheaper rate than you could make it yourself ordering each grass separately.

HEATING A SMALL GREENHOUSE (*Cestrea*).—We are sorry that you are in such trouble with your iron stove. We really think you should try and regulate it so that it should not give out so much heat. All that we have met with are easily regulated by the opening at the ashpit pan. The pipe going along the back wall must be an advantage. If the heat is so much, you might place a plug in the end of the pipe, with two or three half-inch holes in the plug, to let a moderate current of heated air out. The opening in the pan of the ashpit, however, is the great regulator. We advise you to try such modes, and a pan of water over your stove, before incurring greater expense. We have not seen Mr. Walker's gas hot-water apparatus, but we have no doubt it would answer if properly attended to, whether set outside or inside. Before making any change in this respect, read what Mr. Fish says about heating such a small house, by a small flue beneath the floor or path. If you make a furnace outside low enough, the bricks and tiles for the flue would not cost much; and, to save the expense of a brick chimney, you could have lengths of hard-burned earthenware, some 7 inches in diameter, though 6 inches would do. Near a dwelling-house this simple plan does away with all filth in the house, and in cold damp days the pathway is nice for the feet, and no appearance of a heating medium is to be seen. We have no objection to your planting three Vines in the way you propose, and then dividing each into two main stems as they enter the house; but if you do so you will not do much good with plants in your house in summer. You may, however, have these six stems of Vines in an 18-foot house, and keep the house filled all the winter and early spring with bedding and other plants. You would need at least 36 feet of three-inch piping for such a house, and, unless gas was cheap, that would be no joke. We think gas is best applied to very small houses. Before the Vines cover the roof you might have about ten trees in pots—say four Plums, four Peaches, and two Figs; but, after the Vines pretty well cover the roof, you will not do much with these pots, unless the Vine-stems are 6 feet apart. None of these things will ripen their wood, and perfect their fruit, without plenty of light. You might keep Plums, Cherries, &c., in these houses until the fruit was safe, and then place the plants out of doors; but then you must take care you do not give them a check, or that will neutralise all your labour.

CONSERVATORY ARRANGEMENTS (*M. E. G.*).—We fear you are attempting to grow too great a variety of plants in one house, for if you plant eight Vines as you propose, and train them up the rafters of the house, they being only some 4 feet apart, you will not be able to grow Peaches or Cherries successfully under them, nor would the flowering plants do very well trained to an east wall in such a house, nor the Fig thrive on a north wall, though it would do as well as most things in such a position. Of creepers, according to your proposed arrangements for the pillars, *Bigonia jasminoides*, *Mimosa prostrata*, *Jasminum gracile*, *Rhynchospermum jasminoides*, *Sollya limosaria*, *Lonicera fragrantissima*, *Mandevilla arborescens*, *Kennedya ovata*, *Inophylla*, *Coccinea*, *monophylla*, and *Marrubium*; and *Lapageria rosea*. Of these some are sweet-scented others not. Of Grapes, have two Black Hamburgs, two Lady Downes', two West's St. Peter's, and two White Tokay or Muscat of Alexandria. The best of Figs is the Brown Turkey or Lee's Perpetual. The plants you name for covering the east wall are as good as any; they may do fairly, and as for Peaches and Cherries you will be better without the latter, and if you have the former they should be either pyramids or bushes in pots. Peaches and Nectarines would do very well for the first two or three years, but not so well after the Vines cover the roof, for they would shade the Peaches too much. Neapolitan Violets, bulbs, &c., would do very well along the front. We caution you against attempting too much. Have the Vines and a few plants, and do them well.

CROQUET LAWN LEVELLING (*A. M. S.*).—Now, when the weather is mild, is as good a season as any to level a lawn. Your proposed plan of paring off the turf and filling up the hollow places, is right, only do not pare the turf too thin in taking it off, for it might kill the grass. If the surface be very uneven it would be the best plan to unturf the whole space required to be made quite level, and to level it and then relay the turf. The turf should not be taken off thinner than 1½ inch. By only taking up the turf in the hollows and filling up these with earth, it is quite as likely that the fresh soil will settle considerably, and the surface be but little more even than before, besides in patching it is seldom that the new will unite well with the old turf. Unless the hollows are very low a little soil put there so as to bring them level with the general surface would not be bad, and to sow the pieces with seeds in March; but if the lawn is very uneven the best plan would be to take off the turf from the whole, level the soil and relay the turf. You may proceed with either mode in open weather until May; but the earlier the work is done the less necessity there will be to water in dry weather. The "Cottage Gardener's Dictionary" is a good work of reference. Either it or "Thompson's Gardener's Assistant," we think would suit you.

**CONCRETE WALKS** (*New Forest*).—We believe Mr. Beaton mixed the chalk or lime with the stones, &c. This foundation mixture was put 6 inches deep, and then consolidated by watering and rolling until only 3 inches deep.

**CHRYSANTHEMUMS DONE BLOOMING** (*N. C. Nenaoh*).—A cold frame, protected from severe frost, is the best place for them. Divide the roots in March, continuing them in the cold frame until the young suckers become established. For flowering in the October they should not be stopped after the middle of June.

**CURATE'S VINEY** (*Tyro*).—One Vine will be enough, especially if you do not intend to increase the length, which we should recommend you to double. Choose the Black Hamburg, procure your plant at once, plunge it in leaves or ashes in front of a south wall, and plant in the first fortnight in March. The "Vine Manual" will tell you how. We should prefer twenty-one-ounce sheet glass to that which you name.

**FLOWER-GARDEN PLAN** (*M. P.*).—If you made a geometric garden in the two square pieces in front of the houses, we think the present flower-border should be dispensed with, unless a similar border is made on the opposite side, and even next the kitchen garden, so as to conceal it, which would be still better helped by an evergreen hedge there, or wall, or other boundary. This would leave the sides open next the gravel walk in front of the houses. We cannot undertake to give plans for flower gardens, but merely to criticise those sent, which we will be glad to do in your case. You will find very good hints as to the mode of filling such squares in our engravings of Putteridge Bury and Treatham; and in our little manual of "Flower Gardening" (which you can have free by post for five stamps), such as half of the plan marked in the manual No. 3, the central part of No. 5, or, for simplicity, the end part of No. 6.

**WAREHOUSE CONVERTED TO A GREENHOUSE** (*E. H.*).—1. Having a lofty wall of a warehouse, we do not see the necessity for cutting down that wall to 11 feet in height at back. Why not have had it 16, or 13, or more feet, as the wall was there, and left the wall in front a foot or two higher? Then the roof would have been longer and steeper, the latter being good either for late or early Grapes. 2. The sunk path in front will now be chiefly useful in getting at the Vines over the pathway. If the front wall had been higher that sunk pathway might have been dispensed with, and the border been made right across the house. 3. In that case you might have planted near the front of the house, and also at the back of the house; but if so close as 2 feet apart, you would obtain no fruit against the wall, nor on the upright part of the Vines in front, after the roof was covered. You may also plant only one set of Vines near the middle of the house, train a single stem up to the trellis and then divide it taking one stem to the front and one to the back, and these respectively may be spurred with safety. 4. You seem to plant two sets of Vines behind and near the pathway. We see no difficulty in spurring them from the ground to the trellis, as well as along the roof; but the spurs on the lower part of the stem will only succeed so long as the roof from that part to the front of the house is free of foliage. 5. The whole mode of fixing and strengthening the roof is good. Take care some patentee do not come across you. 6. The mode of ventilation is also good and simple. 7. We are glad your improved Kiddean-system of heating answers so well, but were not quite prepared to learn that the opening of a sluice in the sunk path would so effectually heat the shut-off cold part of your house. We think that would be still more effectually done were you to open a similar sluice or ventilator at the highest corner in the division between the two houses. This system is nicely worked in similar heated and cold houses, by Messrs. Lane, of Berkhamstead.

**PEACH TREE FORCING** (*H. Rose*).—First-rate Peaches have been grown by the help of the common brick fire. The soil of many gardens will grow Peaches well. In planting such nice new houses it would have been advisable to concrete the clay subsoil, and place 20 inches of fresh soil above it, such as you describe you have collected, but with very little of the manure you speak of in it. It is better to give that when needed by top dressings. Your operations outside are all right, with, perhaps, the exception of having enough of dung; but your employer should have allowed you to take up in 1861 the trees that were planted in 1860, and replant them properly in fresh soil; and a smaller border, or none for the first year, would have done outside. The heat you have by hot water ought to be ample, and you seem to have plenty of means of ventilation. To prevent mildew we can only recommend air-giving early, plenty of it, and heat given in proportion, and cooling your hot-water pipes with sulphur and lime. We fear you have used your black sulphur and softsoap too strong and too early, and, perhaps, too hot. Why use black sulphur, or what is called so, when true yellow flowers of sulphur are so easily obtained? You had better syringe your trees a little, and that will ease the buds. We knew an instance of Vines and Peaches being killed by an application of sulphur vivum, softsoap, and tobacco in too warm a state. We have little doubt as to the Vines doing well but in your climate do not mix much dung with the soil.

**NAMES OF FRUITS** (*Bolton*).—Nos. 1, 2, 3, 4, Christie's Pippin; 5, London Pippin; 11, 19, 20, 21, and 22, all the same, but not recognised; 12, and 13, Nelson Codlin; 24, Royal Russet; 28, Hurthouse; 31, Cockle Pippin. Others not recognised.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### BRAHMA POOTRAS.

I AM sorry to see so many disputes as to whether those fowls are a pure breed or cross-bred with the Cochin, &c. "Facts are stubborn things." There are two gentlemen residing in the borough of Barnstaple, who have resided at Brahma, and one of them, Mr. Tanner, kept them there twenty-seven years since. Many years ago I saw him looking at my Brahma, of Miss Watts's breed, he remarked, "You have Brahmas here. I kept them for years in Brahma. In that country there are some grey, others nearly white, and a few buff and white."

The other gentleman, Mr. Falconer, tells me that they are in Brahma as common as the barn-door fowl in England.

If any one would call on me, I would with pleasure introduce him to those gentlemen, who are prepared to prove those birds derive their name from their native place, however they may be imported into England.—H. LEWORTHY, *Newport, Barnstaple.*

[We are exceedingly obliged by this communication, which fully sustains our opinion that the Brahma Pootra is a variety of the Cochin-China. Mr. Tanner says that in Brahma, usually known as Birmah, or the kingdom of Ava, there are Buff Brahma Pootras, and White Brahma Pootras, and no ornithologist could point out a specific difference between them and Cochin-China fowls. These are known to be natives of China, and the products of China find a large market in Birmah, which is its near neighbour. Chit-tangong, we may observe, is one of the boundaries of Birmah.]

### WEST CUMBERLAND POULTRY SHOW.

THE seventh annual Show of Poultry, Pigeons, Rabbits, and Canaries was held on Wednesday and Thursday the 28th, and 29th, of December, in the Oddfellows' Hall, Whitehaven, and a more successful Exhibition was certainly never held under the auspices of the Society. The liberality with which the Committee's appeals for subscriptions was responded to by the public made it practicable to offer £40 more in cups and money than last year, the effect of this being an increase of entries to 491, or 141 more than last year. Both as regards number and quality the Show was a decided improvement on any previous year, the liberality of the prizes having drawn exhibitors from many distant parts of the kingdom, our local fanciers having thus opportunities of comparing the merits of their stock with the best models. The labours of the Committee and Secretaries must have been very great, and too high commendation could not be given to the two latter (Mr. E. Fearon and Mr. Lyon) for their indefatigable exertions in reducing the classes to order.

For the silver cup given to the best Game cock (confined to West Cumberland) there were eighteen entries, the first prize being won by Mr. John Mitchell, Egremont, Mr. Gunson, of Sandwith, however, running him very close. For the silver cup offered for the best Game cock (open to all England) there were sixteen pens of birds shown by some of the most famed breeders in the kingdom. There was also a very fair show of Game cockerels. There were not many Game Bantams, but the specimens shown were excellent. The Gold and Silver-laced Bantams were also comparatively few in number, but it would be difficult to conceive anything more perfect than were some of the birds shown. The prize pen, shown by Mr. Roy, of Kelso, were priced at £500, and though this of course was a "fancy" value, there is no doubt they would fetch a very high sum. There were sixteen entries of *Cochin-Chinas*, and a better lot could scarcely be got together. The Golden and Silver-spangled *Hamburgs* were a very numerous class, almost every bird being a model of this useful and ornamental class. The odd-looking *Black Spanish* were also represented well both as to quality and quantity. In *Ducks* there were some perfect marvels, a *White Muscovy*, shown by Mr. Sisson, weighing 13 lbs. There was also a pen of *Harlequin Ducks*, which surprised every one by the beauty of their plumage.

Perhaps the greatest advance upon last year was observable in the Rabbit class, some of those shown being perfect monstrosities in those particular points which delight fanciers' eyes. *Pigeons* were well represented, some of the pairs being of great value. The pair of *Turbits* which won the first prize in this class were pronounced by the Judge as fit to go anywhere for competition. One pair of *Nuns* were remarkably perfect, but the quick eye of the Judge detected that they had been clipped, and they were consequently disqualified. There was really a large number of *Fantails* and *Almond Tumblers*, perfection being very nearly reached in these classes. There were also several excellent pairs of *Owls* and *Mammoth Runts*.

*Canaries* were considered rather short in number; there were some very perfect specimens shown, however, the bulk of this class having been bred by local fanciers. The cynosure of the ladies' eyes, however, was undoubtedly the stand

of eggs, and the array of silver prizes which surmounted it, Mrs. Wood, of Sandwith was the successful competitor for the handsome egg-stand offered for the best dozen eggs, this being her second victory in this line, on both occasions with eggs laid by the same hen—a cross between Game and Black Spanish.

It is almost impossible that every one can be satisfied with the award of prizes in every class; and it is therefore very seldom that complaints are publicly noticed. In connection with the present show, however, there is one matter which seems to be worthy of the consideration of the Committee. It is assumed that the object of confining some of the prize cups to West Cumberland is that of encouraging local breeders, and a complaint urged during the show was, that some of these prizes had been awarded to birds obtained from breeders at a distance. The reply is that West Cumberland ultimately gets the advantage; but the parties aggrieved are not satisfied with this answer, and contend that if the object of the prizes be as above stated, such prizes should be given only to birds not merely the property of but bred by breeders resident in the district.

It was a pretty general remark that if the society's success should continue in the same ratio, there will not next year be any room in the town sufficiently large for the show. This, however, is a matter which may safely be left in the hands of so able a Committee, and we trust that they will not relax in their efforts to provide an Exhibition which, though to some merely an amusement, is to others a means of instruction, and to the community at large an undoubted benefit.—(Cumberland Packet.)

The following are the awards:—

#### SINGLE COCKS.

**GAME** (Confined to West Cumberland).—First and Cup, J. Mitchell, Egremont. Second, J. Gunson, Sandwith, near Whitehaven. Third, J. Wilson, St. Bees. Highly Commended, J. Brough, Carlisle. Commended, S. Sherwin, Whitehaven.

**GAME**.—First and Cup, A. Ashburner, Ulverston. Second and Third, J. Fletcher, Stoneclough, Manchester. Fourth, A. B. Dyas, Madeley, Salop. Highly Commended, Miss K. Charlton, Manningham, Bradford. Commended, J. Geldert, Collincroft, Kendal; J. Hodgson, Bradford. *Cockerel*.—First and Cup, R. Pickering, Carlisle. Second, M. Billing, jun., Erdington, Birmingham. Third, A. B. Dyas. Highly Commended, T. Dyson, Halifax; J. Wallis, Wigton; T. Robinson, Wigton.

**GAME BANTAM** (Confined to West Cumberland).—First and Cup, J. Naile, Frizington, near Whitehaven. Second, H. J. Nicholson, Whitehaven. Third, W. Cooper, Hensingham.

**BLACK SPANISH** (Confined to West Cumberland).—First and Cup, J. Gunson, Sandwith. Second, W. Cooper, Hensingham. Third, J. Bowman, Workington.

**SILVER GREY DORKING** (Confined to West Cumberland).—First and Cup, E. Fearon, Hensingham. Second, W. Cooper, Hensingham. Third, J. Towerson, Whitehaven.

**GOLDEN-SPANGLED HAMBURG** (Confined to West Cumberland).—First and Cup, E. Fearon, Hensingham. Second, J. Wilson, St. Bees. Third, S. Jefferson, Whitehaven. Highly Commended, S. Jefferson; J. Wilson. Commended, W. G. R. Jones, Whitehaven.

**GAME** (Black-breasted and other Reds).—First, J. Geldert, Kendal. Second, M. Billing, jun., Erdington, Birmingham. Third, H. Thompson, Milnthorpe, Westmoreland. Commended, J. Brough, Carlisle.

**GAME** (Ducking and other Greys and Blues).—First, L. Casson, Ulverston. Second, M. Billing, jun., Erdington, Birmingham. Third, J. Hodgson, Bradford.

**GAME** (Any other variety).—First, H. Thompson, Milnthorpe (Piles). Second, J. Brough, Carlisle. Third, E. Fearon, Hensingham (Black). Commended, J. Brough (Black). *Pullets*.—First, W. Cooper, Hensingham (Black Red). Second, J. Perry, Netherby, Carlisle (Brown Reds). Third, Capt. C. Fisher. Highly Commended, D. Tait, Grasmere (Black Red). Commended, J. Mitchell, Egremont; F. L. Roy, jun., Kelso.

**SPANISH** (Black).—First, W. Bayliss, Walsell. Second, J. Biggar, Ecclefechan. Third, E. J. Wood, Manchester. Highly Commended, H. Beldon, Gilstead. Commended, E. Brown, Sheffield. *Chickens*.—First, W. Newsome, Bingley. Second, E. Brown. Third, J. Biggar. Highly Commended, Mrs. W. C. Biggar, Maidstone; J. Wilson, St. Bees. Commended, H. Beldon; J. Wilson.

**DORKINGS** (Silver Grey).—First, R. Cousins, Whitehaven. Second and Third, R. D. Holt, Windermere. *Chickens*.—First, D. Steele, Windermere. Second, R. D. Holt. Third, T. Atkinson, Coniston. Highly Commended, F. R. Pease, Southend, Darlington.

**DORKINGS** (Any other variety).—First, H. Beldon, Gilstead (Dark Grey). Second, T. Rogers, St. Helens (Dark Grey). Third, C. W. Brierley, Middleton, Manchester (White). Highly Commended, J. Robinson, Garstang (Coloured); W. Cooper, Hensingham (White).

**COCHIN-CHINA** (Any variety).—First, J. Nood, Chorley, near Preston (Buff). Second, Miss E. A. Aglonby, Grasmere (Partridge). Third, J. Biggar, Ecclefechan (White). Highly Commended, J. Biggar (White); T. Stretch, Ormskirk (White); R. J. Wood, Lower Cumpsall (White); E. Smith, Middleton, Manchester (Buff). Commended, J. Cattell, Birmingham (Buff); F. M. Hindle, Haslingden (Buff).

**BRAMA POOTRA** (Any variety).—First, H. Lacy, Hebden Bridge. Second, F. R. Pease, Southend, Darlington. Third, J. Poole, Ulverston. Highly Commended, H. Beldon, Gilstead.

**HAMBURGERS** (Golden-spangled).—First, H. Beldon, Gilstead. Second, D. Tait, Grasmere. Third, J. Robinson, Garstang. *Chickens*.—First, R. Tate, Leeds. Second, J. Preston, Bradford. Third, W. G. R. Jones, Whitehaven.

Highly Commended, J. Robinson; H. Beldon. Commended, W. Emerson, Whitehaven.

**HAMBURGERS** (Silver-spangled).—First, J. Robinson, Garstang. Second, H. Beldon, Gilstead. Third, J. Smalley, Blackburn. *Chickens*.—First, J. Robinson. Second, H. Beldon. Third, J. Smalley. Highly Commended, E. Collinge, Middleton, Manchester.

**HAMBURGERS** (Any other variety).—First, J. Robinson. Second, W. Smith, Halifax. Third, H. Beldon. Highly Commended, C. Moore, Preston. *Chickens*.—First, H. Beldon (Pencilled). Second, J. Robinson, Garstang (Pencilled). Third, R. Tate, Leeds (Black-pencilled). Highly Commended, C. Moore (Silver-pencilled).

**POLAND** (Any variety).—First and Second, H. Beldon, Gilstead. Third, C. W. Brierley, Middleton, Manchester.

**BANTAMS** (Game).—First, C. W. Brierley, Middleton, Manchester. Second, J. Munn, Newchurch, Manchester. Third, Miss Aglonby. Highly Commended, R. Pickering, Carlisle; T. Robinson, Ulverston; F. R. Pease, Southend, Darlington; J. Crossland, jun., Wakefield.

**BANTAMS** (Gold and Silver-laced).—First, F. L. Roy, jun., Kelso. Second, F. R. Pease, Southend, Darlington. Highly Commended, C. W. Brierley, Middleton, Manchester.

**BANTAMS** (Any other variety).—First, J. Crossland, jun., Wakefield (White). Second, F. R. Pease, Southend, Darlington. Highly Commended, H. Beldon, Gilstead (Black).

**ANY NEW OR DISTINCT VARIETY NOT PREVIOUSLY MENTIONED**.—First, E. Smith, Middleton, Manchester (Sultans). Second, W. F. Dixon, Moresby (Russian). Third, R. Loft, Woodmansay, Beverley (Sultans).

**ANY DISTINCT CROSS**.—First and Second, S. Jefferson, Whitehaven (Cochin and Dorking). Third, J. H. Wilson, St. Bees (Black Spanish and Golden-spangled Hamburg). Highly Commended, E. Fearon, Hensingham (Brahma Pootra and Dorking). Commended, S. Jefferson (Brahma Pootra and Cochin-China).

**DUCKS** (Aslesbury).—First, J. Smith, Grantham. Second and Third, F. M. Hindle, Haslingden. Highly Commended, J. Robinson, Garstang. Commended, H. Beldon, Gilstead.

**DUCKS** (Rouen).—First, T. Robinson, Ulverston. Second, Miss Lowther, Distington. Third, W. G. R. Jones, Whitehaven. Highly Commended, A. Dickinson, West Croft; S. Sherwin, Whitehaven. Commended, W. Stampert, Brigham, Carlisle; M. Mawson, Frizington; J. Ross, Carlisle.

**DUCKS** (Any other variety).—First, H. Beldon, Gilstead. Second, J. R. Jessop, Hull (East Indian). Third, J. Gunson, Sandwith (Muscovies). Highly Commended, R. Pickering, Carlisle; W. Sisson, Whitehaven (White Muscovies); J. B. Jessop (Wild Ducks).

#### PIGEONS.

**CARRIER**.—First and Cup, W. Stalker, Liverpool. Highly Commended, W. B. Van Haansbergen, Newcastle-on-Tyne; H. Beldon, Gilstead; E. Brown, Sheffield. Commended, M. Irwin, Whitehaven.

**CARRIERS**.—First, H. Yardley, Birmingham. Second, E. Brown, Sheffield. Highly Commended, W. Stalker, Liverpool. Commended, J. R. Robinson, Sunderland.

**TUMBLERS** (Almond).—First, W. Stalker, Liverpool. Second, E. Brown, Sheffield. Highly Commended, W. Stalker; F. Key, Beverley.

**TUMBLERS** (Bald-headed).—First, J. W. Edge, Birmingham. Second, W. Stalker, Liverpool. Commended, G. Birckett, Whitehaven; S. Sherwin, Whitehaven.

**TUMBLERS** (Any other variety).—First, R. Pickering, Carlisle. Second, J. & W. Towerson, Egremont. Highly Commended, H. Beldon, Gilstead. Commended, R. Thompson, Kendal.

**POWERS**.—Prize, J. & W. Towerson, Egremont.

**FANTAILS**.—First, W. B. Van Haansbergen, Newcastle-on-Tyne. Second, H. Beldon, Gilstead. Highly Commended, F. Key, Beverley; H. Yardley, Birmingham. Commended, J. W. Edge, Birmingham.

**JACOBS**.—First, E. E. M. Roys, Rochdale. Second, R. Pickering, Carlisle. Highly Commended, J. R. Robinson, Sunderland; H. Beldon, Gilstead; J. Thompson, Bingley.

**TRUMPETERS**.—First, J. K. Robinson, Sunderland. Second, W. B. Van Haansbergen, Newcastle-on-Tyne. Highly Commended, J. R. Robinson; F. Key, Beverley.

**BARBS**.—First, W. B. Van Haansbergen. Second, H. Yardley. Highly Commended, H. Beldon. Commended, R. Thompson, Kendal.

**TURBITS**.—First, R. Thompson. Second, H. Yardley. Highly Commended, J. W. Edge, Birmingham.

**OWLS**.—First, R. Pickering, Carlisle. Second, J. W. Edge. Highly Commended, J. R. Robinson, Sunderland; E. E. M. Roys, Rochdale; H. Yardley; J. & W. Towerson, Egremont.

**RUNTS**.—First, S. Sherwin, Whitehaven. Second, M. Irwin, Whitehaven. Highly Commended, E. Fearon, Hensingham.

**ANY OTHER VARIETY**.—First, W. B. Van Haansbergen (Victorias). Second, J. W. Edge, Birmingham. Highly Commended, W. B. Van Haansbergen (Isabels); J. & W. Towerson (Magpies); Commended, H. Yardley.

#### CANARIES.

**BELGIAN** (Yellow).—First, H. Thompson, Maryport. Second, W. Lyon, Whitehaven. Highly Commended, J. Walker. Commended, S. Todd.

**BELGIAN** (Buff).—First, H. Stephenson, Whitehaven. Second, T. Doughall, Carlisle. Highly Commended, H. Stephenson. Commended, S. Todd, Whitehaven; G. Bryden, Whitehaven.

**MULE** (Yellow).—Prize, T. Doughall, Carlisle.

**MULE** (Buff).—First, W. Swinburn, Whitehaven. Second, J. Walker, Whitehaven. Highly Commended, J. W. Colville, Egremont; J. Walker. **PIEBALD** (Yellow or Buff).—First, R. Bowness, Frizington. Second, J. Walker, Whitehaven. Highly Commended, J. Willens, Whitehaven; J. Rigg, Arlecdon; D. Bryan, Whitehaven. Commended, J. Willens; M. Middleton, Arlecdon; A. Birnie, Whitehaven.

**LIZARD** (Gold and Silver-spangled).—First and Second, J. Walker, Whitehaven.

#### RABBITS.

**LOP-EARED**.—Prize, W. H. G. Fearon, Hensingham.

**LOP-EARED**.—First, J. W. Colville, Egremont. Second, G. Jones, Birmingham. Third, E. E. M. Roys, Rochdale.

**ANY OTHER VARIETY**.—First, J. P. Hedley, Whitehaven (Angola). Second, W. Taylor. Third, T. Weeks, Cumberland (Angola).

**JUDGES**.—*Poultry*: Richard Teebay, Esq., Fullwood, near Preston. *Canaries*: Anthony Benson, Esq., Whitehaven.

### ABERDEENSHIRE POULTRY SHOW.

THIS Exhibition was held at the Artillery Gymnasium, Queen Street, Aberdeen, on Wednesday, Thursday, and Friday, the 4th, 5th, and 6th inst.

**SPANISH.**—First and Cup, Rt. Hon. Viscountess Holmesdale, Linton Park, Kent. Second, Messrs. Brown & Cochrane, Perth. Third, Mrs. M. U. B. Cross, Monifieth, near Dundee. *Chickens*.—First, Viscountess Holmesdale. Second, W. Meff, Aberdeen. Third, G. Wallace, Aberdeen. Very Highly Commended, W. Hay, Aberdeen.

**DORKINGS.**—First and Cup, Rt. Hon. Viscountess Holmesdale. Second, E. Tudman, Whitechurch, Salop. Third, Lord Kinnaird, Inchture. Very Highly Commended, Mrs. M. U. B. Cross, Monifieth, near Dundee; Messrs. Brown & Cochrane, Perth; J. Elsworth, Glasgow. Highly Commended, Rev. J. F. Newton, Kirby-in-Cleveland; F. R. Pease, Southend, Darlington. *Chickens*.—First, Viscountess Holmesdale. Second, W. Meff, Aberdeen. Third and Very Highly Commended, J. Anderson, Meikle. Highly Commended, J. Gordon; W. Meff. Commended, Mrs. Black, Banchoy.

**COCHIN-CHINAS.**—First and Cup, Messrs. Brown & Cochrane, Perth. Second, E. Tudman, Whitechurch, Salop. Third, C. T. Bishop, Lenton, Nottingham. Very Highly Commended, C. T. Bishop; Viscountess Holmesdale. Highly Commended, G. Murray, Aberdeen. Commended, G. Fell, Warrington; Mrs. A. Guy, Grantham. *Chickens*.—First, Viscountess Holmesdale. Second, G. Fell. Third, C. T. Bishop.

**GAME.**—First, J. Anderson, Meikle. Second, J. M'Nab, Barrhead, near Glasgow. Third, J. Wood, Wigan. Highly Commended, J. Mollison, Meikle; Mrs. M. U. B. Cross. *Chickens*.—First and Second, J. Anderson. Third, J. Wood. Highly Commended, Mrs. Rennet, Aberdeen; W. Robertson, Glasgow.

**HAMBURGS (Golden or Silver-pencilled).**—First, Viscountess Holmesdale. Second and Cup, G. Wallace, Aberdeen. Third, J. M'Innes, Paisley. Very Highly Commended, R. Hemingway, Shelf, near Halifax.

**HAMBURGS (Golden-spangled).**—First, Viscountess Holmesdale. Second, H. Beldon, Bradford. Third, Mrs. Stronach, Aberdeen.

**HAMBURGS (Silver-spangled).**—First, Viscountess Holmesdale. Second, H. Beldon. Third, J. M'Nab, Barrhead, near Glasgow. Highly Commended, J. Milne, Port-Elphinstone; Mrs. M. U. B. Cross, Monifieth. Commended, Capt. C. L. Hay, Kinnethmont.

**POLANDS.**—First and Second, H. Beldon. Third, F. E. Pease, Southend, Darlington.

**BANTAMS.**—First, J. Anderson, Meikle. Second, Mrs. M. U. B. Cross. Third, F. R. Pease. Highly Commended, J. Anderson; F. R. Pease; Mrs. M. U. B. Cross; W. Hodgson, Darlington; H. Beldon.

**BRAMA POOTRAS.**—First and Cup, R. W. Boyle, Dundrum, Dublin. Second, Mrs. M. U. B. Cross. Third, Mrs. H. Barclay, Kinross. Very Highly Commended, Mrs. Carnegie, Fordoun. Highly Commended, Lord Kinnaird; Mrs. F. Leith, Alford; R. W. Boyle. Commended, F. R. Pease.

**ANY OTHER PURE BREED.**—Very Highly Commended, H. Beldon (Black Hamburgs).

**GESE.**—First, F. R. Pease. Second and Third, Lord Kinnaird.

**DUCKS (Aylesbury).**—First, Mrs. Carnegie, Fordoun. Second, Lord Kinnaird. Third, H. Beldon. Highly Commended, W. Forbes, Pitcape, Aberdeen.

**DUCKS (Any other variety).**—First and Third, J. Anderson, Meikle (Rouen and Black East Indian). Second, Mrs. Cochrane, Perth (Rouen). Highly Commended, Lord Kinnaird (Rouen); Mrs. F. Leith, Alford (Rouen); Mrs. Carnegie, Fordoun (Rouen). Commended, Lady Gladstone, Fasque, Kincardineshire (Rouen); A. Farquhar, Elsick, near Stonehaven (Rouen).

**TURKEYS.**—First, F. R. Pease. Second, Lady Gladstone. Third and Highly Commended, Lord Kinnaird.

**SELLING CLASS.**—First, W. Meff, Aberdeen (Spanish). Second, J. R. Robinson (Duckwing Game). Third, Mrs. Rennet, Aberdeen (Game). Highly Commended, A. F. Williamson, Caskieben (Dorkings).

**SINGLE COCKS.**—*Spanish*.—First and Second, W. Meff, Aberdeen. Third, W. Hay, Aberdeen. *Dorking*.—First, G. Campbell, New Pitligo. Second, Mrs. Black, Banchoy. Third, G. Wallace, Aberdeen. *Cochin-China*.—First, Mrs. Tocher, Aberdeen. Second and Third, W. Hendry, Aberdeen. *Game*.—First and Cup, J. Fletcher, Stoneclough, Manchester. Second, R. Swift, Nottingham. Third, M. Billing, jun., Erdington, Birmingham. Very Highly Commended, Miss J. A. Aytrold, Bradford; J. Anderson, Meikle; Mrs. M. U. B. Cross. Highly Commended, J. M'Nab, Barrhead, Glasgow. Commended, Mrs. M. U. B. Cross. *Hamburgh*.—First, T. Knowles, jun., Aberdeen. Second, J. Ness, Kirkcaldy. Third, Mrs. Stronach, Aberdeen. *Brahma Pootra*.—First, A. B. Milne, Auchindachy. Second, Mrs. H. Barclay, Kinross. Third, J. Masson, Keith.

### PIGEONS.

**POWTELS.**—First and Medal, M. Sanderson, Edinburgh. Second and Third, J. Hay, Aberdeen. Highly Commended, F. Macrae, Aberdeen. Commended, J. R. Robinson, Sunderland.

**FANTAILS.**—First and Medal, W. J. Van Haansbergen, Newcastle-on-Tyne. Second, J. Rae, Guestrow. Third, J. Hay, Aberdeen. Highly Commended, J. Baillie, Aberdeen. Commended, H. Beldon, Bradford.

**CARRIERS.**—First and Medal, T. Colley, Sheffield. Second, F. Macrae, Aberdeen. Third, J. R. Robinson, Sunderland. Highly Commended, T. Knowles, jun., Aberdeen. Commended, J. R. Michie, Stoneywood, near Aberdeen.

**TUMBLERS.**—First and Medal, J. R. Robinson. Second, J. Bell, Newcastle-upon-Tyne. Third, M. Sanderson, Edinburgh. Highly Commended, H. Beldon. Commended, J. Hay.

**JACOBS.**—First, J. R. Robinson. Second, H. Beldon. Third and Highly Commended, J. Baillie, Aberdeen. Commended, T. Knowles, jun.

**ANY OTHER VARIETY.**—First, J. R. Robinson (Trumpeters). Second, A. Murray, Aberdeen (Blue Turbits). Third, H. Beldon. Highly Commended, A. Murray (White Trumpeters). Commended, J. R. Robinson (Turbits).

### CANARIES.

**BELGIAN (Yellow).**—*Cock*.—First, J. Mitchell, Aberdeen. Second, J. Milne, Aberdeen. Third, W. Wilson, Aberdeen. *Hen*.—First and Second, W. Donald, Aberdeen. Third, J. Leeds, Aberdeen. *Cock of 1864*.—First, A. Barnett, Aberdeen. Second, W. Donald. Third, J. T. Garden, Aberdeen. Highly Commended, Mrs. A. Smith, Aberdeen. *Hen of 1864*.—First, W. Donald. Second, J. Mitchell. Third, A. Donald, Aberdeen.

**BELGIAN (Buff).**—*Cock*.—First, W. Donald. Second, J. T. Garden. Third, J. Mitchell. Highly Commended and Commended, J. T. Garden. *Hen*.—First, R. Smith, Inverury. Second, W. Wilson. Third, A. Middleton. Highly Commended, R. Smith. *Cock of 1864*.—First, J. Hunter, Aberdeen. Second, J. Garden. Third, A. Catto, Woodside. Highly Commended, A. Donald. *Hen of 1864*.—First and Third, J. Hunter. Second, J. Fraser, Woodside. Highly Commended, J. Mitchell.

**BELGIAN (Fleeced).**—*Cock*.—First, A. Barnett. Second, D. M'Kay, Aberdeen. Third, W. Anderson, Aberdeen. Highly Commended, J. Falconer, Aberdeen. *Hen*.—First, J. Falconer. Second and Third, A. Middleton. *Cock of 1864*.—First, W. Anderson. Second, J. Falconer. Third, J. T. Garden. Highly Commended, W. Anderson. Commended, G. Gill, Banchoy. *Hen of 1864*.—First and Second, A. Middleton. Third, J. Milne.

**SCOTCH FANCIER.**—First and Second, R. Ross, Aberdeen. Third, J. Nicol, Aberdeen. Highly Commended, R. Ross. Commended, A. Middleton.

**GOLDFINCH MULE.**—First, D. Wright, Aberdeen. Second and Third, J. Hunter.

**JUDGES.**—*Poultry*: Mr. J. Douglas. *Pigeons*: Mr. Frame, Overton, Carluke.

### PAISLEY ORNITHOLOGICAL EXHIBITION.

THE eleventh annual Exhibition of Poultry, Pigeons, Canaries, and other small birds, held under the auspices of the Paisley Ornithological Association, took place January 2nd, in the large building in William Street, belonging to P. Coats, Esq., of Woodside and which, as for several years past, was kindly granted to the Association by that gentleman for the purpose. The entries were more numerous, it is believed, than has ever been the case before at any similar Exhibition in Scotland; and a better collection could not have been brought together, as it included the choicest prize fowls and birds from all parts of the country. Owing to the disagreeable condition of the weather, the turn out of ladies was not so great as we have seen on previous occasions, but otherwise the attendance was excellent, as all the departments were crowded from the opening to the close.

The following is a list of the awards:—

**SPANISH.**—First and Medal, J. Crawford, Beith. Second, J. Hutchieson, Paisley. Third, J. Urquhart, Ballat. *Chickens*.—First and Medal, A. Mitchell, Paisley. Second, J. Urquhart. Third, J. Shearer, Paisley.

**DORKINGS (Coloured).**—First, Medal, and Cup, J. Elsworth, Campsie Junction. Second, J. Burns, Craigends. Third, T. Barrowman, Cummock. *Chickens*.—First, H. Heys, Springfield House. Second, J. Elsworth. Third, J. Linning, Glasgow.

**DORKINGS (White).**—First, A. Russell, Paisley. Second, J. Aitken, Paisley. Third, A. Jardine, Cardonald.

**CRINEE.**—First, G. Aitken, Kirkintilloch. Second, A. Campbell, Blythwood. Third, G. Tawse, Helensburgh.

**BRAMA POOTRA.**—First, J. Paton, Rigg, Stewarton. Second, A. Campbell, Blythwood. Third, R. Abercrombie, Paisley.

**OLD SCOTCH BREED.**—First, Second, and Medal, W. Thomson, Glasgow. Third, J. Allison, Rutherglen.

**HAMBURGH (Golden-spangled).**—First, Second, Third, and Medal, R. Cunningham, Stewarton.

**HAMBURGH (Golden-pencilled).**—First, Second, and Medal, J. M'Innes, Paisley. Third, J. Paton, Rigg, Stewarton.

**HAMBURGH (Silver-spangled).**—First, J. Watson, Lanark. Second, J. Stewart, North Arthurlie. Third, J. M'Innes, Paisley.

**HAMBURGH (Silver-pencilled).**—First, D. Illingworth, Burley, Otley, Yorkshire. Second, R. Cunningham. Third, J. M'Innes.

**POLANDS (Black and White Crested).**—First and Second, G. Paul, Glasgow. Third, J. M'Innes.

**TOPPED POLANDS (Any colour).**—First and Second, W. Ramsay, Johnstone.

**GAME (Black-breasted and others).**—First and Medal, J. H. M'Nab, South Arthurlie. Second, J. M'Dowall, Johnstone. Third, W. Robertson.

**GAME (Any other colour).**—First, Second, and Third, A. M'ulloch, Trees.

**BANTAMS (Game, any colour).**—First, J. Taylor, jun. Second, P. Catterson, Grahamstone, Barrhead. Medal, J. Turner, Barrhead. Commended, A. Campbell, Blythwood.

**BANTAMS (Golden or Silver).**—First, J. Linning, Glasgow. Second, J. Reid, Paisley.

**BANTAMS (Any other kind).**—First, D. Murray, Eglinton Castle. Second, J. C. Nelson, Airdrie. Third, W. Morris, Paisley. Highly Commended, W. Morris.

**ANY OTHER VARIETY.**—First, J. C. Nelson, Airdrie. Second, A. Campbell, Third, R. Loft, Beverley, Yorkshire.

**DUCKS (Aylesbury).**—First and Third, H. Hey, Barrhead. Second, A. Sym, Townholm, Kilmarnock.

**DUCKS (Any other kind).**—First, A. Campbell, Blythwood. Second, G. Aitken, Kirkintilloch. Third, A. M'ulloch, Trees.

### PIGEONS.

**POWTELS.**—First, W. Lightbody, Glasgow. Second, W. Neilson, Johnstone. Third, J. Mitchell, Glasgow.

**CARRIERS.**—First, G. Wallace, Burnbank, Glasgow. Second, R. Fulton, Shandon Cottage, London. Third, J. Muir, Glasgow.

**FANTAILS.**—First, W. B. van Haansbergen, Newcastle-on-Tyne. Second, J. Muir, Glasgow. Third, G. Wallace, Burnbank, Glasgow.

**RUFFS.**—First, R. Loft, Beverley, Yorkshire. Second and Third, R. Barclay, Paisley.

**TUMBLERS (Short-faced).**—First and Second, M. Stewart, Glasgow. Third, G. Wallace, Burnbank, Glasgow.

**TUMBLERS (Any other kind).**—First, T. Short, Glasgow. Second, J. Sharp, Johnstone. Third, R. Blair, Johnstone.

ANY OTHER DISTINCT BREED.—First, J. Cook, Williamsburgh. Second, J. Sharp, Johnstone. Third, W. Neilson.  
COMMON PIGEONS.—First, J. Sharp, Johnstone. Second, W. Neilson, Johnstone. Third, J. Seclar, Kilmarnock.

## SMALL BIRDS.

PAIRS FOR SILVER MEDAL.—First (Silver Medal), J. M. Lauchlan, Paisley. Second, T. Allison, Paisley. Third, J. Crawford.

YELLOW.—Cock.—First, T. Buchanan, Glasgow. Second, W. M'Kechnie, Paisley. Third, A. Mitchell, Paisley. Fourth, J. M'Catter, Glasgow.  
HEN.—First, G. Masterton, Glasgow. Second, J. Muir, Kilmarnock. Third, R. S. Wylie, Paisley. Fourth, J. Wilson, Galston.

BUFF.—Cock.—First, R. Fleming, Paisley. Second, W. Weir, Paisley. Third, R. Hill, Hamilton. Fourth, J. Glen, Paisley. HEN.—First, W. Houston, Paisley. Second, G. Masterton, Glasgow. Third, J. Templeman, Glasgow. Fourth, M. Bell Glasgow.

PIEBALDS FOR CAGE.—Prize, J. Hamilton.  
PIEBALD (Yellow).—Cock.—First, H. Fisher, Glasgow. Second, J. Young, Dalry. Third, J. M'Vey, Paisley. Fourth, G. Masterton, Glasgow. HEN.—First, J. Wilson, Galston. Second, R. White, Paisley. Third, W. Robertson, Paisley. Fourth, J. O'Brien, Greenock.

PIEBALD (Buff).—Cock.—First, H. Fisher, Glasgow. Second, J. Laugland, Kilmarnock. Third, A. Robertson, Glasgow. Fourth, J. Kirkland, Beith. HEN.—First, R. Wood, Paisley. Second, J. Fulton, Beith. Third, R. S. Wylie, Paisley. Fourth, G. Hamilton, Beith.

GOLDFINCH MULE COCK (Yellow).—First, J. Shearer, Paisley. Second, A. Glen, Erskine.

GOLDFINCH MULE COCK (Buff).—First, A. Hogg, Oakley. Second, J. Muir, Kilmarnock.

GOLDFINCH.—First, J. Haddow, Kilwinning. Second, H. Hill, Hamilton.

BULLFINCH.—First, J. Burns, Craigends. Second, J. Johnstone, Glasgow. —(Glasgow Daily Herald).

## FIFE AND KINROSS ORNITHOLOGICAL SOCIETY.

The annual Show of this Society was held in the Corn Exchange, Kirkcaldy, on the 2nd and 3rd inst., when the following prizes were awarded:—

DORKINGS.—First, J. Taylor, Deven Vale House. Second, Countess de Flahault, Tullyallan. Third, J. Stocks, West Bridge. Chickens.—First J. Spalding, East Fall. Second and Third, J. Stocks. Highly Commended Countess de Flahault.

SPANISH.—First, R. Semerville, Edinburgh. Second and Third, R. Dixon, Kirkcaldy. Chickens.—First, R. Somerville. Second, W. Hay, Aberdeen. Third, J. Hunter, Kirkcaldy.

HAMBURGS (Spangled).—First, J. Ness, Pathhead. Second and Third, W. Keddie, Cowdenbeath.

HAMBURGS (Pencilled).—First, D. Penman, Boreland. Second and Third, J. Ness, Pathhead. Highly Commended, J. Ballingall. Commended, H. Brown, Coalton of Balgonie.

GAME (Black and Brown Reds).—First, A. Spalding, Kirkcaldy. Second, R. Stark, Kirkcaldy. Third, A. Moyes, Kinghorn. Chickens.—First and Third, J. L. Anderson. Second, T. Anderson, Kirkcaldy.

GAME (Grey and others).—First, J. Gilmour, Milton, Balgonie. Second and Third, J. C. Aitken, Leslie.

BANTAMS (Any variety).—First, R. Spalding (Game). Second, Countess de Flahault (Japanese). Third, W. Hay, Aberdeen. Commended, A. Hutton (Gold-laced).

ANY OTHER BREED.—First, Second, and Third, Countess de Flahault (Polands, Buff Polands, and Poulda la Flèche).

DUCKS (Aylesbury).—First, Mrs. Anderson, Chapel House. Second, J. Mungall.

DUCKS (Any other breed).—First, Countess de Flahault (East Indian). Second, J. Kidd (Blue).

GAME COCK (Any variety).—First, D. Penman, Boreland. Second, A. Spalding. Third, J. Anderson, Kirkcaldy.

DORKING COCK.—First, J. Spalding, East Fall. Second, J. Menzies. Third, J. Stocks. Highly Commended, D. Normand, Kennoway. Commended, Countess de Flahault.

SPANISH COCK.—First, R. Somerville, Edinburgh. Second, W. Hay, Aberdeen. Third, R. Aitken, Edinburgh.

COCHIN COCK (Any variety).—First, Mrs. Oswald. Second, Lord Loughborough. Third, J. Y. Craig.

PIGONS.—Tumblers.—First and Second, E. Spence, Musselburgh. Fan-tails.—First, — Soutar, Carstairs. Second, Miss Purvis, Jedburgh. Pouters.—First, J. Grant, Edinburgh (White). Second, J. S. Christie, Kirkcaldy. Any other variety.—First, W. Veitch, jun., Jedburgh (Trumpeters). Second, Miss Purvis (Red Jacobins). Commended, — Soutair (Nuns).

## CANARIES.

SCOTCH FANCY (Yellow Cocks).—First, W. Bonthron, jun., Kirkcaldy. Second, A. Welsh, Edinburgh. Third, J. Tweedie, Kely.

SCOTCH FANCY (Buff Cocks).—First, J. Smith, Dundee. Second, J. Mitchell, Perth. Third, W. Poyet, Edinburgh.

SCOTCH FANCY (Yellow Hens).—First, R. Veitch, Leith. Second, J. Edwards, Dundee. Third, G. Greig, Edinburgh.

SCOTCH FANCY (Buff Hens).—First, R. Hunter, Oakley. Second, R. Smith, Dundee. Third, J. Stephenson, Dundee.

BELGIAN (Yellow Cocks).—First, J. Hay, Dundee. Second, R. Forsyth, Edinburgh. Third, W. Pitcaithly, Dunfermline. Hens.—First, R. Forsyth. Second, W. Bonthron, jun., Kirkcaldy. Third, J. Hay, Dundee.

BELGIAN (Buff Cocks).—First, S. Crawshaw, Dundee. Second, J. Clark, Kirkcaldy. Third, J. Hay, Dundee. Hens.—First, R. Forsyth, Edinburgh. Second, J. Hay, Dundee. Third, A. Hope.

PIEBALD (Yellow Cocks).—First, J. Smith, Dundee. Second, A. Chalmers,

Woodside. Third, W. Kidd, Edinburgh. Hens.—First, J. Stephenson, Dundee. Second, J. Ford, Freuchie. Third, J. Kerr, Perth.

PIEBALD (Buff Cocks).—First and Third, J. Smith, Dundee. Second, W. Broadfoot, Portobello. Hens.—First, D. Allen, Leith. Second, G. Greig, Edinburgh. Third, W. Bonthron, jun.

PIEBALD GOLDFINCH MULES (Yellow).—First and Second, D. Laing, Kirkcaldy. Third, W. Kirk.

PIEBALD GOLDFINCH MULES (Buff).—First, W. Kirk, Dunfermline. Second, Sergeant Swanston, Wemyss. Third, J. Wishart, Kirkcaldy.

JUDGES.—Poultry: Mr. W. C. Hardie, Carron. Pigeons: Mr. D. Stewart, Perth. Canaries: Mr. M. Bell, Glasgow; Mr. G. Binnie, Perth.

## DUMFRIES AND MAXWELLTOWN ORNITHOLOGICAL SOCIETY.

This Society held its sixth Exhibition and competition of Canaries, Poultry, Pigeons, and Parrots in the Mechanics' Hall, Dumfries, on Monday and Tuesday. The Exhibition was a very attractive one, the best, we believe, that has yet been held in connection with the Society or in the district. The Canary department showed careful and successful breeding. On former occasions there have been larger entries, but never so many fine birds. The prize Canaries in all the departments were beautiful creatures, but even the eye of a connoisseur must have had great difficulty in determining the awards. The Goldfinches and Mules exhibited were also particularly fine.

The poultry was a very large and fine show—especially in the Game fowls and Dorkings—and the Hamburgs, Cochins, Chinas, and Brahma Pootras exhibited, although not so many, were very beautiful specimens. The Bantams were well contested, and many fine birds brought forward. The Pigeon department was one of the most attractive of the Exhibition, the show being very large and excellent.

The following is the prize list:—

## CANARIES.

SCOTCH FANCY (Yellow).—Cocks.—First, Second, Third, and Medal, J. Thorpe, Dumfries. Hens.—First, J. Graham, Kilmarnock. Second and Third, J. Harding, Maxwelltown.

SCOTCH FANCY (Buff).—Cocks.—First, J. Graham. Second, J. Thorpe. Third, J. M'Alister, Dumfries. Hens.—First, J. Harding. Second, J. Graham. Third, T. Conchie, Drumpark.

PIEBALD (Yellow).—Cocks.—First and Medal, J. Thorpe. Second, J. Harding. Third, R. M'Cubbin, Annan. Hens.—First, J. Thorpe. Second, J. Graham. Third, E. Edgar, Maxwelltown.

PIEBALD (Buff).—Cocks.—First, J. Thorpe. Second, R. Edgar. Third, J. M'Alister. Hens.—First, J. Harding. Second, J. Scott, Dumfries.

BELGIAN (Buff).—Cocks.—Prize, J. Beeby, Carlisle. Hens.—Prize, J. Harding.

BELGIAN (Yellow).—Hens.—Prize, J. Beeby.

GOLDFINCH MULES (Yellow).—First, R. Davidson, Carlisle. Third, T. Doughtal, Carlisle. Prize Card, J. Thorpe.

GOLDFINCH MULES (Buff).—First, R. Davidson. Second, T. Fergusson, Maxwelltown. Third, T. Doughtal.

GOLDFINCHES.—First, R. Davidson. Second, G. Brown, Dunscore Vill age

Third, R. Kerr, Barjarg.

## POULTRY.

GAME (Black Reds and other Reds and Blues).—First, W. D. Dickson, Thornhill. Second, J. Henderson, Dumfries. Commended, J. Fergusson, Wallacestown. Chickens.—Medal, J. Proudfoot, Lochthorn. Second, R. Kerr, Barjarg. Commended, R. Coltart, Dumfries.

GAME (Duckwing and other Greys).—First, M. Wells, Collin. Second, T. Wright, Lockerbie. Chickens.—First, M. Wells. Second and Commended, W. Henderson, Dumfries.

DORKINGS.—Medal, G. M'Holm, Hillhead. Second, W. Maxwell. Commended, W. F. H. Arundel, Barjarg. Chickens.—First, J. Maxwell, Dalswinton. Second, R. Jardine, Moffat. Commended, T. W. Campbell.

HAMBURGH (Golden-spangled).—First, Mrs. Blacklock, Lockerbie. Second, W. Currie, Maxwelltown. Commended, J. Glover, Dumfries. Chickens.—Medal, J. Little, Moffat. Second, D. Hill, Ruthwell. Commended, D. Dickson, Moffat.

HAMBURGH (Golden-pencilled).—First, T. W. Campbell. Second, Mrs. Blacklock. Chickens.—First and Second, M. M'Mahon, Lochanhead. Commended, R. Brownrigg, Keir.

HAMBURGH (Silver-spangled).—First, W. Johnston, Speddoch Mill. Second, J. M'Court, Dumfries. Commended, M. Dewar, Maxwelltown. Chickens.—First, S. Boyes, Blairbinnock. Second, R. M'Gregor, Beltridding. Commended, Mrs. Waugh, Lochmaben.

HAMBURGH (Silver-pencilled).—First, D. M'Knight, Brownhill. Second, W. Currie. Commended, R. Young, Lochbarbriggs. Chickens.—Medal and Second, R. Young. Commended, T. Wright.

BRAHMA POOTRAS.—Prize Card, Mrs. Gordon. Chickens.—First and Second, Mrs. Gordon. Commended, Mrs. Waugh.

SCOTCH GREYS.—Prize Card, D. Dickson. Chickens.—Prize Card, T. Maxwell, Dumfries.

SPANISH (Black).—Chickens.—Medal, Mrs. Smith, Broomhills. Second, T. Maxwell. Commended, — Little, Lockerbie.

ANY OTHER DISTINCT BREED.—Prize, T. Tait, Mosshead (White Crested).

**POLISH (White-crested).**—Prize, J. C. Perry, Browningstown, Cork.  
**POLISH (Silver).**—First, R. P. Williams, Dublin. Second, Miss Pike, Besborough. Highly Commended, R. P. Williams, Dublin.  
**HAMBURGERS (Golden).**—First, J. C. Perry (Pencilled). Second, Mrs. Dring, Rockgrove.  
**HAMBURGERS (Silver).**—First, R. P. Williams, Dublin (Spangled). Second, T. O'Grady, Roughgreve, Bandon. Highly Commended, J. A. Fitzpatrick, Cork (Spangled).  
**BANTAMS (Sebright).**—First, J. A. Fitzpatrick. Second, F. R. Pease, Darlington. Highly Commended, J. A. Fitzpatrick.  
**BANTAMS (Game).**—First, J. A. Fitzpatrick, Cork (Duckwings). Second, F. Hodder, Templelawn. Highly Commended, F. W. Zurhorst, Donnybrook; Dublin; R. J. Harvey, Cork (Brown Reds); A. E. Usher, Camphire, Cappoquin.  
**JAPANESE SILKIES.**—First and Second, F. Hodder, Templelawn.  
**ANY VARIETY.**—First, Hon. Mrs. C. M. Smyth, Ballinatr (Rumpies). Second, F. R. Pease (Black Hamburgs). Highly Commended, J. C. Perry (Cornish and Guinea Fowl).  
**TURKEYS.**—First, R. W. Boyle. Second, A. C. Sayers, Cork (Cambridge). Highly Commended, A. E. Usher (Cambridge). Commended, R. Briscoe, Fermoy (Cambridge and American). *Poultis.*—First, R. W. Boyle, Dundrum (Cambridge) Second, R. Briscoe (Cambridge). Highly Commended, Hon. Mrs. C. M. Smyth (Paragua).  
**GESE.**—First and Second, R. W. Boyle, Dundrum (Various). Highly Commended, P. Ducrow, Windsor, Douglas (Chinese); Countess of Bandon, Castle Bernard (Chinese). Commended, Miss A. Deable, Strandville, Rochestown. *Goslings.*—First, R. W. Boyle. Second, G. Langtry, Malahide, Dublin (Toulouse). Highly Commended, Miss A. E. Pike, Cork (Danubian). Commended, Mrs. T. Daly, Cork (Toulouse).

**DUCKS (Aylesbury).**—First, R. P. Williams, Dublin. Second, J. C. Perry, Browningstown, Cork. Highly Commended, Countess of Bandon, Castle Bernard. Commended, J. W. Dyas, Blackrock. *Ducklings.*—First, R. P. Williams, Dublin. Second, Hon. Mrs. H. B. Bernard, Bandon.  
**DUCKS (Rouen).**—First, R. P. Williams, Dublin. Second, N. D. Parker, M.D., Carrigrohau, Cork. *Ducklings.*—First and Second, R. W. Boyle, Dundrum, Dublin.  
**ANY VARIETY.**—First, Miss A. E. Pike, Besborough, Cork (Muscovy). Second, R. P. Williams (Call Ducks). Highly Commended and Commended, P. Ducrow, Windsor (Muscovy).  
**MRS. LYONS'S MEDAL.**—Medal, T. O'Grady. Very Highly Commended, F. Hodder, Templelawn. Highly Commended, W. Joyce, Waterford.

**PIGEONS.**

**POWTERS (Yellow-pied).**—First, Dr. Harvey, Cork. Second, A. E. Usher, Camphire.  
**POWTERS (Black-pied).**—First, J. H. Perrott, Hayfield, Cork. Second, Dr. Harvey, Cork.  
**POWTERS (Blue or Silver-pied).**—First, J. H. Perrott, Hayfield, Cork. Second, Dr. Harvey. Commended, Dr. Harvey.  
**POWTERS (Red-pied, Mealy, or other Colour).**—First, Dr. Harvey, Cork (Red). Second, J. H. Perrott (Mealy). Commended, Dr. Harvey (Grizzled and White); J. H. Perrott, Hayfield, Cork (Red and Checker); R. Fulton, Deptford, London.  
**POWTERS (White).**—First, Dr. Harvey, Cork. Second, R. Fulton, Deptford. Commended, J. H. Perrott, Hayfield.  
**CARRIERS (Black).**—First and Second, G. A. Wherland, Cork. Highly Commended, P. Goulding, Cork; G. A. Wherland. Commended, J. H. Perrott; G. A. Wherland.  
**CARRIERS (Dun).**—First, R. Lane, Blackrock Road. Second, G. A. Wherland, Cork. Highly Commended, P. Goulding, Cork; R. Lane. Commended, G. A. Wherland.  
**CARRIERS (Blue or others).**—First and Second, G. A. Wherland, Cork.  
**TUMBLERS (Short-faced, Almonds).**—First, R. Fulton, Deptford. Second, Dr. Harvey.  
**TUMBLERS (Short-faced, Kites).**—First, Dr. Harvey, Cork. Second, G. A. Wherland, Cork.  
**TUMBLERS (Short-faced, Mottles, or others).**—First and Second, T. Hare.  
**TUMBLERS (Short-faced, Balds or Beards).**—First, Dr. Harvey (Blue and Balds). Second, J. W. Edge, Birmingham (Balds).  
**TUMBLERS (Common, Balds or Beards).**—First, J. Pike, Besborough (Balds). Second, R. Russell (Red).  
**TUMBLERS (Common, Any other colour).**—First, J. O'Leary. Second, J. Pike, Cork.  
**BARBS (Black or Dun).**—First and Second, G. A. Wherland (Black). Highly Commended, J. H. Perrott.  
**BARBS (Any other colour).**—First and Commended, G. A. Wherland (Red). Second, J. H. Perrott (Red).  
**JACOBS (Red or Yellow).**—First, J. W. Edge, Birmingham. Second, Miss A. E. Pike, Besborough (Yellow).  
**JACOBS (Any other colour).**—First, R. Russell, Cork (White). Second, J. Perry.  
**FANTAILS (White).**—First, J. Pike, Besborough. Second, A. E. Usher, Camphire, Cappoquin.  
**FANTAILS (Any other colour).**—First, J. Pike, Cork (Blue). Second, J. W. Edge, Birmingham.  
**OWLS (Blue or Silver).**—First and Commended, A. E. Usher (Silver). Second, J. H. Perrott.  
**OWLS (Any other colour).**—Prize, J. W. Edge, Birmingham.  
**TRUMPETERS (Mottles).**—First, J. H. Perrott. Second, A. E. Usher.  
**TRUMPETERS (Any other colour).**—First and Commended, J. H. Hutchison, Dublin (Yellow). Second, J. Dowling, Blackrock (White).  
**TURBITS.**—First, J. W. Edge. Second, T. O'Grady, Bandon.  
**NUNS.**—First, T. O'Grady. Second, J. W. Edge.  
**MAGPIES.**—Prize, P. Goulding, Cork.  
**ANY OTHER VARIETY.**—First, J. W. Edge. Second, Dr. Harvey (Pigmy Powters and Isabells).  
**SWEETSTAKES.**—*Powter* (Any colour).—Prize, R. Fulton, Deptford. *Carrier* (Black).—Prize, P. Goulding. *Tumbler* (Short-faced).—Prize, T. Wilde, Drogheda (Almond).  
**SILVER MEDAL (Best pair of Irish-bred Carriers).**—Medal, P. Goulding.  
**SILVER MEDAL (Best Powder cock).**—Medal, Dr. Harvey (Red).

**SONG BIRDS.**

**CANARIES (Yellow).**—First, Mrs. Hodder, Templelawn. Second, J. Kilden, Cork. Commended, M. J. Collins, Cork.  
**CANARIES (Green).**—First, E. Keating (Belgian). Second, J. Looney.  
**CANARIES (Mealy or Pied).**—First, A. Veitch, Cork (Yellow-pied). Second, Mrs. Hodder (Pied). Commended, W. P. Harris, Blackrock.  
**GOLDFINCH MULES.**—Prize, J. Concoran.  
**LINNET MULES.**—First, E. Keating, Cork. Second, W. A. Hill.  
**BLACKBIRDS.**—First, W. A. Hill, Cork. Commended, J. Lloyd, Cork.  
**THRUSSES.**—First, W. P. Harris. Second, T. M'Swaine (Speaking).  
**Extra Prize, J. B. Birchley (White).**  
**WOODLARKS.**—Prize, R. Lane.  
**SKYLARKS.**—First, R. J. Perry. Second, J. Lennie, Cork. Commended, R. Daly.  
**GOLDFINCHES.**—First, J. Concoran. Second, Mrs. Hodder, Templelawn.  
**LINNETS.**—Prize, J. Desmond, Cork.  
**NOT CLASSED.**—Very Highly Commended, W. E. Hill, Cork (Foreign Birds). Highly Commended, E. Keating (Caged Birds); W. E. Hill (Rosellas and Cockateals). Commended, W. E. Hill (Indian Cockateal).  
 The Judges were Mr. Tegetmeier for Poultry, Mr. Wolstenholm for Pigeons.

**NORTH BRITISH COLUMBIAN SOCIETY.**

The awards made at this Show, held at Glasgow on the 23rd and 24th ult., appeared in our Number of the 27th, and we now supply a few remarks. The great feature was the collection of Powters; no less

than 189 birds of this variety competing in the various classes, and they were considered, in point of excellence, to be greatly in advance of any previous Meeting, scarcely an inferior bird appearing. With the exception of three classes for birds bred in 1864, which were shown in pairs, the Pouters were shown singly.

In the first class for the best pair of Pied Pouters, Yellows excepted, bred in 1864, a silver medal was presented by Mr. John Geddes, jun. The medal was awarded to Mr. Stuart for a very fine pair of Blues, the cock being especially good, though rather too heavily-feathered in limb; the second and third prizes both going to capital Blacks. The class contained many good birds, but most of the pairs were unevenly-matched in some respect. For Yellow-pied Pouters, bred in 1864, Mr. Montgomery of Belfast offered a medal, which Mr. George Ure won very easily with a fine pair; one of the pens noticed receiving commendation more from a desire to encourage an increase in birds of this colour than for their own merits. Mr. Miller's medal for the best pair of Whites, bred in 1864, only brought half a dozen pens, but some very promising birds competed, the three pens noticed being particularly good, and shown in fine condition. In the class for Black Pouter cocks Mr. Ure had first with a remarkably lengthy, well-shaped, well-coloured bird. Mr. Montgomery's highly commended young cock will, we fancy, be heard of again to his owner's credit. White Pouter cocks formed one of the finest classes in the Show, Mr. Maclean being first with a very graceful well-proportioned bird shown in fine condition, just over 19 inches in feather, and very nearly 7 inches in limb, to which was also awarded the special prize of a portrait in oil of the best Pouter in the exhibition. Adjoining were three brothers of the above, one taking second, and the others each receiving high commendations. The class also contained other good representatives. Blue Pouter cocks numbered 23, and were an unusually good class. The first-prize bird was particularly finely-shaped, but rather out of condition, measuring 19½ inches in feather, with a capital limb over 7 inches in length, the peculiarity of the wing-bar—a sort of mixture of Kite and Black—being objectionable. The second special prize for the best Pouter in the Show was also awarded to this bird. Several very fine Blue cocks received notice. In Red Pouter cocks Mr. Wallace had first with a fine lengthy bird rather faulty in colour, the second being a better Red, but shorter and rather gay. For the best Yellow Pouter cock the entry was only small; the prize birds were, however, very fine. In Pouter cocks, Any other colour, a good-shaped Mealy was first, and a Checker second, several pens receiving high commendation. A particularly good cock was shown in this class; the bird was a bad coloured Red, capital in points, and should have been in the class for Reds. An extraordinarily fine splashed cock, said to be 20 inches in length, with proportionate limb, had also to be passed over, having become crop-gorged, and it was suspended in a stocking in an adjacent room during the first day. In the class for Black Pouter hens the first and second-prize birds were very even, both being excellent, the difference of a quarter of an inch in feather at length deciding the first position in favour of Mr. Stuart. White Pouter hens only numbered seven, but were exceedingly fine, almost every bird being worthy of a first prize. Blue Pouter hens were more numerous, but were not of equal merit; the prize birds, however, were good, and well worthy of their honours. In Red Pouter hens Mr. Ure had both prizes with particularly good representatives. For Yellow Pouter hens Mr. Ure completely outdistanced competition, the first-prize bird being one of the very best in the Show, and quite unapproachable in the colour. In the class for Pouter hens, Any other colour, a good Mealy had first, and a Checker second.

It is not perhaps out of place to mention that the Sunderland birds arrived a day too late, and there is no doubt the prize-list would have been considerably altered had Mr. Potts's birds competed, the most noticeable being his extraordinary Red cock and hen, and a remarkably good Blue hen.

The silver medal for the best pair of young Carriers, presented by Mr. James Wallace, was awarded to first-class Duns belonging to Mr. Else. The Carrier classes were well filled. Mr. Colley took the special prize for the best Carrier in the Show with a capital Dun hen.

Almond and Short-faced Tumblers were fair classes.

The silver medal for the best pair of young Barbs only brought four pens, Mr. Frame being successful with Blacks, both being promising birds, but difficult to distinguish as to sex, and the colour an unusual Black. In the class for Barbs the first-prize Yellows were good, but not looking in such condition as on the last occasion in which they came under our notice. The second-prize Black cock was very good, but orange-eyed, and only indifferently accompanied.

In the class for Fantails a silver medal, presented by Mr. Stuart, brought a large entry. Mr. Else took the medal with a plain-headed pair, and, although slightly sullied in feather, they were small, short-backed, fine, and with capital tails. The second prize went to a very small pair, good in carriage, but narrow and contracted in tail.

Jacobins and Turbits were average classes.

In Trumpeters Mottles were first, and Whites second. A first-class pair (Mottles) belonging to Mr. Robinson arrived too late for competition.

Good White Owls were first, and Blues (Foreign) second, in the class for the variety, the competition being very poor.

Any other breed did not contain anything requiring particular notice.

The Pouters occupied nearly the whole of the large room of the hall, all being shown in large circular pens. The other birds were placed in an adjacent room badly lighted. The Judges were not permitted to commence their arduous duties until 1 o'clock, owing to the non-arrival of several of the birds, this delay being the only drawback on the whole management of the Show, which was otherwise most ably carried out by the Committee, and more particularly by Mr. Ruthven, the indefatigable, genial, and courteous Hon. Secretary of the Society. Many birds were sold at large prices.

The awards gave general satisfaction, and we believe we are justified in stating that at no previous exhibition of the Society have the decisions met with such universal approbation.

## POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.

(Continued from page 17.)

### NATURAL HATCHING.

The hens of all kind of gallinaceous fowls sit for twenty-one days; Ducks of the usual kind—such as Aylesbury, Rouen, and others, twenty-eight days; Muscovy Ducks, from thirty to thirty-five days; Geese, thirty to thirty-five days; Guinea fowls, from twenty-eight to thirty days; Turkeys, twenty-eight days; Pea hens, from twenty-eight to thirty days.

With the view of obtaining more eggs in a given time from a fowl, many writers suggest preventing a hen from sitting by cooping her up in a dark place on a low diet. Nothing can be more cruel than to force Nature without giving that necessary rest which overwork requires. Already domesticated fowls lay many more eggs than wild ones between their hatchings, and by a judicious housing and feeding they can be made to lay still more, but then it is absolutely necessary to allow the hen to recruit her strength by a rest of twenty-one days on her nest and a liberal and suitable diet, as laying, and more particularly that of large eggs, is attended with considerable pain, as is evidenced by the difference in the sound hens make before and after laying, and also by their uneasiness whilst on the nest. Besides, domesticated fowls are naturally of a sociable disposition, and to separate a hen from her companions and to keep her on a low diet when she requires rest and nourishing food to recruit her strength, after she has become exhausted from the pain of laying and the drain on her constitution by the rapid formation of her eggs, is the height of cruelty, and would surely not be practised were breeders aware of the injury they do to the health of their hens.

I do not say that hens should be permitted to rear their brood, as that would be waste of time and very hard work to a kind mother who will but ill-feed herself to provide as much as possible for her young (she has rest neither day nor night, as she is compelled to remain in an unnatural position to cover her young ones, and this can be performed with greater success by artificial mothers, as will be explained hereafter);

but what I do advise those persons who have a regard for the health of their fowls and their own interest, is to allow Nature her own way by giving a hen her twenty-one days' rest, and during that period a quiet place and nourishing poultaeous food, after which time she can be returned to her own home when, in a few days, she will recommence laying.

When a hen wants to sit she utters a peculiar cluck, ruffles her feathers, wanders about, searches for dark corners and recesses, and is evidently ill at ease. She is feverishly hot and resolutely takes to a nest in which there are eggs, whether of her own production or not matters little to her. At this time a hen will allow herself to be separated from her companions and placed in solitary confinement without fretting, provided she has a nest and eggs to sit upon. It is not advisable to allow a hen to hatch in her ordinary home and amidst her companions, who are fond of usurping her nest and laying fresh eggs in it.

The incubating compartment should be composed of two chambers. See *fig. 14*.

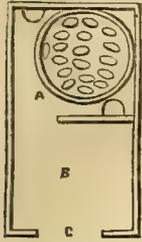

Fig. 14.—Plan of Hatching-room.

A Is the hatching room or nest, near which food and water are suspended to enable the hen to refresh herself without having to leave the nest, which she does reluctantly.

B Is the dressing-room in which she performs her ablutions in gritty dust.

C Is a glazed door over which a perforated zinc plate is fixed for the ventilation of the pen. Warm moisture being necessary to the hatching of strong and healthy chickens, as evidenced by wild birds and hens that sometimes unobserved will hatch a brood under a hedge in the fields,

I recommend the sitting-nest to be made of earthenware, as in *fig. 5*, the same as for laying, with this difference, that a fresh-cut piece of turf should be placed on the sand and on it the eggs should be put. The heat of the hen will

soon generate steam, but whenever the turf becomes too dry some water may be poured on the sand underneath.

The number of eggs to be placed under a hen must necessarily depend on her size. A Dorking, Cochin-China, Brahma Pootra, or other large breed, can with every certainty hatch at least fifteen eggs; and as regards the selection of the eggs all I can advise is to choose fresh and good-sized ones. Some persons pretend to be able to tell whether an egg is fecundated, and whether it will produce a male or female bird, but these assertions have not as yet been satisfactorily proved.

ARTIFICIAL HENS FOR REARING CHICKENS.

Where poultry breeding is carried on as a commercial undertaking, and where it is intended to rear the greatest number of chickens with the least number of hens, and this without interfering with their laying, artificial mothers are of the utmost importance.

The functions of a hen towards her chickens consist of forming a covering to prevent the natural heat of their unfledged bodies from cooling; also, to break into small pieces any food that is too large for them; and lastly, to protect them against danger. Now, my artificial mothers not only do all this, but they perform these duties a great deal better and with less casualties to the chickens.

Most writers on poultry do not believe in artificial hatching or rearing, yet they might as well doubt growing tropical fruits and plants in England. Chickens neither require artificial heat nor that of their mother; all that is necessary is to provide them with a suitable covering to their bodies until they are fully fledged to preserve the natural heat of their bodies, the same as with infants. During cold weather, however, their home must be warmed the same as for full-grown poultry; then a good ventilation without draught, a dry floor, sun, light, and a small run are likewise needed.

The portable artificial hen particularly recommended to breeders and amateurs, is shown by *fig. 15*, she performs her duties as a mother towards the chickens entrusted to her care with far greater success than a hen could possibly do.

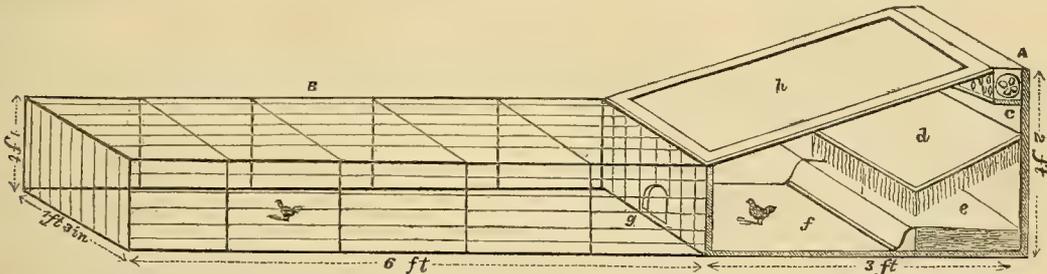

Fig. 15.—Portable Artificial Hen.

A Is a glass-covered frame 3 feet long, 15 inches wide, and 2 feet high at the apex, and 12 inches at the rise of the glass frame. This forms a dry run in wet and cold weather; c, is an air-flue across the frame for the necessary ventilation, and formed of perforated zinc. At each end of this flue a ventilator is fixed by which the admission of air can be regulated according to the temperature of the atmosphere. It will be seen that chickens are not exposed to draught by this arrangement of ventilation; d, is a frame lined with long fleece, under which the chickens will roost the same as under the wings of a hen, and will even prefer the artificial mother, as I have ascertained by experience; e, is about 1 inch deep of ashes which may be sprinkled with flowers of sulphur. This makes a dry and warm footing and retains the heat but the ashes should be renewed or sifted once a-week; f, the floor, should be slightly covered with sand, to be renewed every other day; g, is a small door communicating with the open run; h, is a glass frame made to open by means of a slide or by hinges.

B Is the moveable open run 6 feet long, 15 inches wide, and 12 inches high. It is made of galvanised wire which not only keeps the chickens from danger, but also prevents them from roaming.

The artificial mother being portable should be taken indoors every afternoon during the winter months, and in the daytime be placed on grass or dry land. However, for large breeding establishments the arrangements would be different, and be explained in the artificial rearing home.

THE ARTIFICIAL REARING HOME.

In poultry-breeding establishments of any magnitude the portable artificial mother could not well be used with advantage, its cost and the labour that would be required for a proper attendance on the chickens, are obstacles which cannot be overlooked without loss to the breeder. In fact, as I have stated before, in any large establishment a judicious arrangement for saving labour and for performing the work systematically by subdivision of labour, becomes of the utmost importance in a commercial point of view. Although the principles of the portable mother are strictly retained in the arrangement of the rearing home, yet it will be seen that where many thousand chickens have to be attended to in separate compartments containing not more than twelve each, the building, as shown in *fig. 16*, must necessarily facilitate the work of cleaning, feeding, warming, and general supervision.

A Is a sunk passage lined by brick walls, the floor is formed of concrete with a provision for drainage. Along the whole length of the passage hot-water-pipes should be fixed immediately under the roosting place. A door communicates with the covered run b, and wire-netting c, is fixed over the door for ventilation. The roof of this passage can either be glazed or formed of boards covered with asphalt or felt, but, if glazed, it can be used as a forcing-house. However, provision must be made for efficient ventilation. This passage should be about 5 feet wide between the walls, and 6 feet 6 inches high.

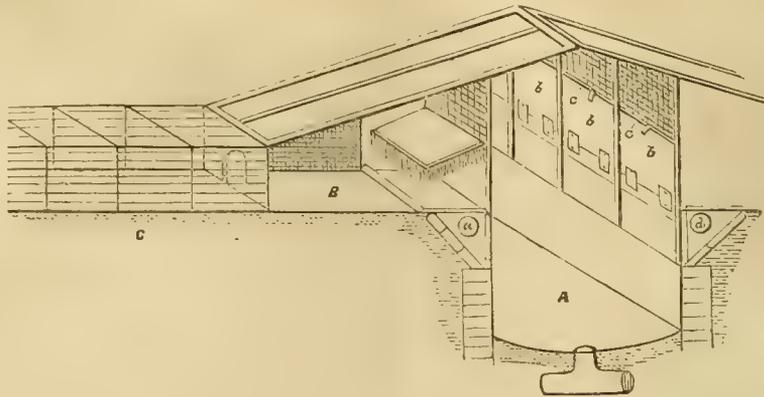

Fig. 10.—Artificial Rearing-home

B Is the glass-covered run. It differs from the portable iron wire-netting, and only the front is made of boards. The floor is made of concrete covered with gritty dust. This run can also with advantage be made a little larger—say, 4 feet long, 13 inches wide, and 2 feet 6 inches high.

C Is the open run. The floor can be made of concrete or gravel, with an incline towards a gutter for quick drainage. The sides and top can be made of galvanised-iron

wire-netting, on the same plan as shown in figs. 9, 10, 11.—G. K. GEYELIN, Civil Engineer, London.

(To be continued.)

### AN ACCIDENT CLEVERLY AND COMPLETELY REPAIRED.

EARLY on the morning of Nov. 30th the central portion of the county of Dumfries was visited by a severe gale, which blew in gusts and whirlblasts, doing considerable damage in places naturally sheltered and little if at all exposed to the direct action of the current. Knowing that my bee-houses were protected from the storm by the intervention of elevated buildings, I felt quite comfortable as to their safety, and slept tranquilly till daybreak, paying little attention to the wind, which one moment would, somewhat lulled, be wildly wailing through the trees, and the next expending itself in a roar, which threatened to sweep everything before it. So little anxiety did I feel about the welfare of my bees, that it was not till about ten or eleven o'clock, when the wind had fallen and the rain ceased, that the thought came into my head to go into the garden and see how they fared. Imagine, then, my mortification when, on nearing the apiary, I found that a shed containing a favourite Ligurian hive had been overturned by the wind, and, as I imagined, rocked to perdition, seeing its upper end had caught and rested in its fall on the stem of a Gooseberry bush.

What was to be done to remedy the evil? The thermometer did not reach 40°, and I knew that if I caused any bees to go abroad they would immediately be thrown into a state of asphyxia and perish; besides, the weather was by no means favourable to any out-door operations, for though the wind had fallen the skies were still lowering. By merely looking at the outside of the hive, which was a Woodbury frame box of the usual dimensions, I could not tell what internal damage had been sustained; and I was afraid to elevate it from the floor-board for the purpose of inspection, lest the combs, being detached, should fall down through the disarranged frames and thus occasion more death and destruction.

It was necessary, however, to do something, and accordingly I began by inverting and replacing gently and gradually, and with the least disturbance possible, the overturned box in its former horizontal position. I then carried it to a room raised by a small fire to a temperature of about 50°, and placed it on a chair close to the window, allowing any bees that chose to come out and fly against it.

My next act was to unscrew the crown-board, slightly raise it, and with a puff from my cigar send the bees helter-skelter down amongst the frames. But what a sight for a compassionate bee-master presented itself when the crown-board was removed and the interior of the hive exposed to view! The floor-board was swimming with honey—hundreds

of the poor bees were drowned in it, and many of them also were crushed between the combs, which lay broken and piled against each other like the tilted strata of geologists: Every comb had parted from its frame, and altogether the pounded-looking mass was a piteous spectacle.

Furnishing myself with a goose feather and a spare Woodbury hive containing only one frame and comb, I commenced operations by putting into it a small piece of comb covered with bees, gently lifted from the ruins. I then removed the frames and pieces of comb in succession, brushing off the bees with a feather into the spare Woodbury-box. The combs and frames, when cleared of the adhering bees, were set aside, and in a short time the operation of transferring all the bees from their original domicile to the spare box was completed. The emptied stock-box with its floor-board was then washed and dried. My next step was to nail slips of wood one-eighth of an inch in thickness by half an inch in breadth along one side of each frame from top to bottom, placing the slips about 2 inches apart. I then laid the frames on a newspaper, the slips being under, and placed the broken combs upon the slips, making the junctions as neat as possible, and keeping the comb close to the top bar. These broken combs I secured by slips laid over them and nailed to the top and bottom bars nearly opposite the other slips. The combs thus encased, though broken into many pieces, could not get out of position, and might readily be handled by the frame. As soon as I managed to get the frames refitted with comb in this manner I returned them to the original box; then, taking the spare box containing the bees, I placed it over the frames, and swept the bees down between them, and afterwards replaced the crown-board.

During the operations many bees flew against the window and fell down benumbed; these I now carefully gathered into a wide-mouthed bottle, and revived by the application of gentle heat, pouring them, as soon as animation returned, amongst their fellows through the central hole in the crown-board. I did the same with those which had been bedaubed or drowned in the escaped honey; and I believe I do not go beyond the truth when I say that the whole remedial process did not entail the loss of a dozen lives, and it was accomplished without either hands or face being in any way protected. An occasional whiff from a pipe or cigar was all that was needed to subdue their resentment whenever any bees showed a disposition to revenge what they could not but regard as insulting.

The reason why the combs were so much broken in this

ill-fated hive can be explained by their newness and the weight of honey which they contained; besides, they only approached the verge of the bottom bars, and consequently were not fastened to them throughout. Had the combs been light and aged the breakage might have been trifling. Now, Dr. Cumming, in one of his letters to the *Times*, said, "The Woodbury hive is no improvement." Had he witnessed the mischief I have described and the complete restoration which followed, I feel confident he would have retracted his words, and admitted, however unwillingly, that in the Woodbury hive *only*, at so inclement a season, could the damage done have been repaired and the lives of the bees saved.

In less than a fortnight I had the satisfaction of seeing the whole of the broken combs mended and firmly fastened to their respective frames, and the hive again in almost as flourishing a condition as it was before it met with the accident. As the slips of wood were no longer necessary either to support or keep the combs in position, I brought my hive once more into the house, took out the frames, and removed the slips.

A hive which permits such operations possesses advantages of no common order, and for experimental purposes the Woodbury frame stands pre-eminent in the estimation of very competent judges. Accidents to hives in winter are much to be regretted, but they are sometimes unavoidable. At that season of the year they ought, if possible, never to be disturbed. When hibernating bees will remain quiescent and almost motionless for several months; but if put into an active state they are obliged, whether the weather will permit or not, to leave the hive and relieve their distended abdomens. When this is the case in a temperature of 40° or less, and there is a breeze at all, myriads depart never to return. I have a great objection to feeding or disturbing hives in any manner from the beginning or middle of October till the beginning or middle of March. This remark, however, only applies to the south of Scotland. In Devonshire, I fancy, the winter is comparatively short, and the cold of North Britain almost unknown.—R. S.

## A NEW CHAPTER IN THE NATURAL HISTORY OF THE BEE.

BEE COMMOTIONS AND QUEEN ENCASEMENTS.  
(Continued from page 20.)

SUCH were my opinions in 1859. I thought that superannuation, debility, and incapacity of the queen had much to do with the phenomena of commotions. Several cases occurring in my apiary shortly after, seemed to justify the impressions then entertained. In these the circumstances and condition of the hives were somewhat identical, and the queens were all aged and declining in strength. In all this I thought I could recognise a uniform principle at work, exhausted fertility and weakness in the queen. Moreover, it was my practice in general, on any commotion being exhibited in a hive, to examine it carefully, and in most instances I found that the queen's encasement was the origin of all the turmoil and excitement among the bees.

Such were my opinions as I have said in 1859. Further experience, however, and increased facilities of observation from the possession of all sorts of hives—observatory, Huber, uncomb, and frame-hives—opened up to me new aspects of this interesting subject. I found that old queens were not alone subjected to these strange encasements. Hives possessing queens two years, and one year old, were not exempted from being thrown into a state of confusion by their queens being encased. Nay, I found that queens only a few weeks old were sometimes the objects of similar treatment, and had to pass through the same ordeal of a rigorous captivity. The whole question now appeared to me more mysterious and unaccountable than ever. Failing to construct any feasible or consistent theory on this *questio vexata*, unable to reconcile conflicting difficulties and explain facts as they presented themselves, I now felt half inclined, I confess, to abandon the subject in despair as inexplicable. Nevertheless, I continued to note down and comment on all the subsequent cases which occurred in my apiary up to the present time. They were more than usually numerous in 1861, 1862, and 1863.

I reared a great number of artificial queens during these years, and hence, especially during the inauspicious season of 1862, several curious cases of youthful princesses being encased presented themselves. At the risk of trespassing, both upon the Editors' space and the reader's patience, it may be, I must be permitted to record two or three of them. They are exceedingly interesting to the naturalist, and, I hope, also, to the practical apiarian. In connection with this subject I may mention, that during these seasons I had some very interesting cases of drone-breeding queens, both among the old as well as the young; and it was in the autumn of 1862 that I sent a couple of queens in an abnormal condition to Mr. Woodbury for microscopic examination of their reproductive organs. The result was communicated in No. 80, of this Journal, 7th October, 1862. I shall confine myself here, however, strictly to the subject on hand. I shall select, therefore, two of the most recent cases which occurred in 1863, inasmuch as other curious facts connected with impregnation of the queen are elicited, independently of the question before us.

Case 1.—On the 18th July, 1863, I dislodged the Ligurian bees and queen from an octagon frame observatory, and introduced in their room a swarm of black bees, minus the queen, in order that they might rear for me some Ligurian princesses. On the 31st, I proceeded to the apiary at 6 a.m., but found that even then I was not too early for my purpose. External evidence was not wanting in discovering to me that the young queen was at large, and had already commenced the work of destruction among her younger rivals. I lost no time in proceeding to work. I drew up the frames one by one until I found her royal highness busily engaged in the very act of demolishing a rival cell, being half imbedded in a cavity near its base nibbling away at it. The young pupa was still alive. I cut out two other royal cells which were untouched, and gave them to hive No. 6, first taking away its own black queen. On the 1st of August (that is the following morning), a young princess emerged from one of these, and the other was broken up and destroyed. On the 15th, I examined the combs but found no eggs had yet been laid. The drones in my apiary had now become very few, and as I had seen the queen repeatedly out afterwards, I knew she had not yet been impregnated. On the 28th, the usual external evidences of the queen's encasement manifested themselves. I immediately opened up the frames and found it even so. I released her from "durance vile" in a state pitiful to behold. She was, however, again encased and kept prisoner for thirty-six hours. I again released her, and I now found that her wings were much torn and tattered, one was broken, and a leg was off. On examining the hive a few days afterwards, I was rejoiced to find her again at liberty and receiving some attention from the bees, but no eggs were yet laid. I examined the hive again on the 12th of September, but the queen had not yet deposited a single egg. I now half despaired of her ever doing so. On the 25th of September, I examined the hive once more and discovered the queen had at last become fertile. I found a small patch of comb containing eggs and grubs, and three or four cells sealed over; but as these were somewhat elongated, and their coverings more than ordinarily convex, I at once concluded that the queen had become a drone-breeder only. Reckoning the age of the sealed larvæ to be eight days, I found that the queen must have begun to deposit eggs on the 17th of September, when she would be exactly six weeks and five days old. On examining this hive shortly afterwards, I was agreeably disappointed to find, that with the exception of a dozen or so of drone brood, all the rest was that of workers. The population of this hive having now become thin, and the majority of the bees rather old for a good-keeping stock-hive, I joined a whole swarm of black bees to it on the 11th of October, and in the spring the queen became one of the most fertile in my apiary.

I have thus been tempted to digress a little from my subject in order to show (and it is not a solitary instance in my experience), that Huber's doctrine on this point—that a queen whose impregnation is delayed beyond the twenty-first day only lays drone eggs, is here thrown to the winds. True, it might be argued that there is here no real evidence that impregnation was delayed beyond the twenty-first day of her life, though she had postponed ovipositing till the

forty-seventh. Yet, reasoning analogically, that as a general rule the queen does lay within a few days after impregnation, we are warranted, I think, in applying the same rule to her conduct in this case, and concluding that impregnation had been so delayed.

Case 2.—On the 11th of August I removed the reigning queen from a unicombe-hive, and inserted therein a royal cell in course of being sealed. The young queen emerged in due time. There were, as I said in treating of the former case, few drones in my apiary at this time (the greater number of my hives having been sent to the heath). Five weeks elapsed, and no appearance of the queen having been fertilised. On the 25th of September I discovered the queen was encased, and in this state she was retained prisoner for two nights. I released her and put her in again at the top of the hive, but she was again surrounded, and I afterwards found her on the board in the midst of a dense cluster of bees apparently maltreating her. Not being desirous to experiment further with this queen, and she being a black one, I permanently removed her.

In addition to these cases I might also advert to one other. In the same summer I was in possession of a young queen also reared artificially—a most insignificant little creature she was, and she continued so long and so frequently to indulge in out-door excursions, that I formed a very bad opinion of her indeed, and so apparently did her own sisters, for they partially encased her at the very entrance of the hive on one occasion, as if determined to put a stop to her profitless wanderings. This queen remained long unfertile, though she ultimately became so; but the colony over which she reigned never prospered. At the close of the autumn I joined a whole swarm to this hive but all in vain. The prolific powers of the queen were evidently at fault, and the following spring she again manifested the same inactivity. Little progress was made in spring and summer. I then removed her and presented her to a queenless hive, but here she was maltreated and rejected. The bees would not have her to reign over them, and I found her the next morning extruded from the hive dead.

These queens, it will be observed, were all reared artificially; and I think it proper here to record an opinion long entertained by me, and borne out, I think, by ample proof in my experience, that such artificially-reared queens are generally less to be depended upon by the apiarian, and are, therefore, more hazardous to the hive than queens reared in the ordinary way. They are usually longer in getting fecundated, and more apt, accordingly, to go astray and be lost. They are also liable to encasement by the bees, and to become defective and abnormal in their character.

I am quite aware that these views do not find a place in the works of our most eminent apiarian authorities; but it is, I am inclined to believe, because their attention has not been experimentally drawn to the subject in all its details—indeed I am not very sanguine even that they will be indorsed by the more esteemed writers in this Journal; but, be this as it may, we must always yield up our opinions to the lessons of experience, and cannot run counter to the “irrefragable testimony of facts.”

At page 19, second column, beginning of fourth paragraph, for “had generally nothing to do with the queen,” read “had generally nothing to do with the loss of the queen.”—J. LOWE.

(To be continued.)

### SUPPOSED BEE PARASITE.

You will find on the bees enclosed one of the Acari. I think they are common on bees after death. They are easily found on any parts of bees when the temperature of the air is not too low. I found many on parts of a few bees' stings after a few days, when I had been examining and comparing the Ligurian bees' sting with the sting of the black bees; but I have also found these Acari on living bees.—A LANARKSHIRE BEE-KEEPER.

[The mites had vanished from the dead bees enclosed, but we have submitted the mounted specimen to Mr. Parfitt, the naturalist, who says:—“The little animal submitted to me for examination I believe to be *Acarus domesticus* (De Geer). From its being found in bee-hives I presume the

hives are damp, or that the floor-boards contain some decomposing matter, such as broken combs and excrementitious matter. I am not aware that this section of the genus *Acarus* feeds upon any living animal, but so far as is known confines itself to decaying substances. If your correspondent would favour you with a few specimens in a quill they would probably reach you alive. We might then be more certain as to the species, as the glass between which the specimen is mounted is so that thick only a very low power of the microscope will touch it—not sufficient for its proper elucidation.”]

BEES NOT SWARMING.—This season has been a remarkable one in regard to bees swarming in Central New York. In some cases not a swarm has issued. We have about forty hives of bees, and have not had a single swarm, such a circumstance never before occurring in our own apiary. The reason why the bees have not swarmed in our apiary is the fact that no drones have been reared in it this season. We never before, in twenty-five years' experience, knew of such a circumstance with our bees. Why no drones were reared we cannot tell; but without drones swarms are useless, as the young queens cannot be impregnated; as the bees, knowing this fact, destroy all the young queens, if any are produced, and in the absence of queens no swarms issue.—(*Rural American.*)

### OUR LETTER BOX.

POULTRY SHOW ANNOUNCEMENTS (*Chateau Yallon*).—You are only one of many who similarly complain that exhibitions of poultry occur to which they would have sent birds had they known that such exhibitions were to take place. We insert in our list all that we are informed of, and if secretaries do not send to us, and if the committees will not advertise, we are not blameworthy. Three shillings and sixpence is the lowest charge, whether the advertisement consists of five lines, or only one, two, or three.

T. ANDREWS, DALE STREET, LIVERPOOL wrote some weeks since for some chickens, but prepayment being required, nothing further has been heard from him by A. C. F. Gurney.

DISEASED PIGEONS (*An Old Subscriber, Paisley*).—Your Pigeons seem to be suffering from a sort of influenza, and I fear the medicine (aloes and pepper) you have been giving will not do much to relieve your patient. I cured one of mine this spring by the following means, and if you like to try it I should be glad to hear the result:—Take one grain of tartar emetic and mix it thoroughly with twelve grains of calomel, divide this into twelve equal parts, and give one in a bread pill each day until the bird improve, after which give a bolus of cod-liver oil and floueverly twelve hours for a few days.—E. P. BRENT.

COVENTRY SHOW (*Pigeon*).—We never heard of it. If secretaries will not inform us, and if committees will not advertise, we have not the gift of clairvoyance. We cannot insert anonymous criticisms.

WATER FOR FOWLS—PROMOTING LAYING (*Hamburgh*).—The best thing to put in fowl's drink, in order to prevent contagion, or infection, is camphor. It is also a perfect cure for gapes. Sulphate of iron, and a few drops of sulphuric acid, are both good things to put in water. All forcing to lay is bad, and buying eggs at a large price. Meat, hempseed, and tallow-chandler's greaves, are the things most commonly given to induce laying.

BARM FOR POULTRY (*E. G. H.*).—We know what barm is, and can easily believe it has valuable properties for poultry. We should, however, rather class it among remedies than foods. After trying everything, we can find nothing so valuable as ground oats mixed with new milk for fattening every kind of poultry save Ducks and Geese.

CONFINED SPACE FOR POULTRY (*Subscriber*).—Put a heap of bricklayers rubbish in one corner of the space (50 by 44 feet), throw as much road sand over the place and under the trees as you can. Let the floor of your poultry-house be 4 or 5 inches above the level of the pen, and it should be gravel or dry earth. You will have no difficulty in keeping Cochins, or Brahma Pootras, or Spanish, and they (six hens and a cock) will do well.

GOLD FISH (*W. A. O.*).—The white parasitical fungus and blindness, one of its effects, are the bane of Gold Fish. The best preventive we know is having the bottom of the tank covered with clean drift sand, which is sharper than pit sand. A cure, when the parasite appears, is said to be effected by placing the fish for a few minutes in water having common salt dissolved in it at the rate of 4 ozs. to the gallon. We occasionally allow pieces of meat floated by being attached to small blocks of wood to be placed in the tank. The fish come and nibble the meat, and this is much better than allowing them to gorge finely shredded pieces.

### LONDON MARKETS.—JANUARY 9.

#### POULTRY.

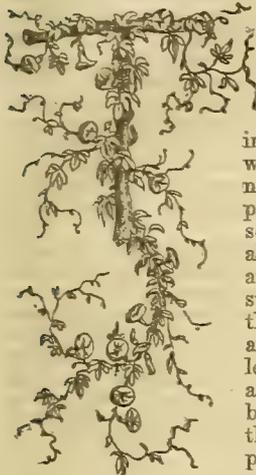

Among the enormous masses of poultry that arrived in London between the 15th and 25th December a proper selection is necessary at market, that the different qualities may be produced when most wanted. It rarely happens that the market is so fully supplied that a demand is found for the lower classes of goods at full price, and that a salesman can accomplish that rare luxury of “a clear shop.” Falling this, a certain quantity must always remain for sale after Christmas-day has passed, and this year has been no exception. This renders it almost impossible to make any quotation for the week following Christmas. A few fresh and good things make large prices, but they are no guide for general sales.

WEEKLY CALENDAR.

Day of M <sup>th</sup>	Day of Week.	JANUARY 17—23, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 43.3°, and its night temperature 31.6°. The greatest heat was 60° on the 19th, 1828; and the lowest cold, 4½° below zero, on the 19th, 1838. The greatest fall of rain was 0.83 inch.

ROYAL HORTICULTURAL SOCIETY.

HERE is still some hope for the Royal Horticultural Society. Notwithstanding the efforts that incompetence, mismanagement, and tinkering have made to render it a by-word in everybody's mouth, and notwithstanding the degraded position to which it has consequently fallen in the opinion of all horticulturists, both at home and abroad, there is hope for it still. There appears, by the steps that are about to be taken, to be an indication of a return to the legitimate objects of the Society, and, therefore, a prospect that, by proper management, and a thorough appreciation of the purpose it was instituted for, we may yet see it taking the position it

ought to occupy in the horticultural world, and which it never ought to have lost. If there ever was a society attempted to be destroyed, that was the Horticultural Society of London; and unless it had possessed an amount of vitality that even the gross mismanagement and incompetence to which it has lately been subjected could not destroy, it must long ago have gone the way of many another good institution, which, unfortunately for itself, could not bear up under such inflictions. By the "Proceedings" that have just been issued, we find that the three gentlemen whom the "horticultural party" voted out, but who tenaciously clung to their seats in defiance of the Charter, at the election of 1864, have seen it their duty to resign, so that there will be, at the next election, an opportunity of having Sir Joseph Paxton, Sir Arthur Buller, and Mr. George F. Wilson, in the place of Sir Wentworth Dilke, Bart., Mr. John Clutton, and Mr. John Lee. Of Sir Joseph Paxton we need say nothing; his horticultural feelings and tastes are well known. Sir Arthur Buller is, we believe, an ardent horticulturist, and well qualified for such a position; and we can speak confidently of Mr. George F. Wilson, F.R.S., whom we know to be not only an enthusiastic and successful horticulturist, but a gentleman of excellent business habits, and great scientific attainments. All of these gentlemen we regard as the type of what ought to constitute the Council of the Society.

But there are two other vacancies, caused by the resignation of Sir Daniel Cooper, Bart., who, on leaving for Australia, read and left behind him a protest against the culpable mismanagement of the Society, and the objectionable system of dictatorship which has crept into the administration of the Society's affairs; and by that of Mr. S. Holmes Godson (not Gordon, as the Assistant Secretary has printed it in the balloting papers), who

resigned, as he stated at the last meeting, because of the offensiveness of the Assistant Secretary, who refused to allow Mr. Godson, though a member of the Council, to inspect the accounts without the sanction of Mr. Cole. In the room of these gentlemen the names of Mr. B. T. Brandreth Gibbs, of Halfmoon Street, Piccadilly, and Mr. Andrew Murray, the late Assistant Secretary, are proposed. In Mr. Gibbs, whose administrative ability has long been apparent in the management of the Smithfield Club Cattle Shows, we should expect to find a valuable addition; and of Mr. Murray we have only to say, if his qualification to sit on the Council rests on the way in which he has filled the office of Assistant Secretary, it is poor indeed.

But who is the Hon. Edwin Portman, who has been appointed Assistant Secretary in the room of Mr. Murray? Where did he earn his horticultural honours? It is usual to throw such an appointment open, so that a choice for the best man may be afforded; but here there has been no such opportunity. There may be men in the horticultural world who are in every way qualified for such an appointment, but we are not aware that they have had a chance of offering their services to the Society. It may be, however, that the Hon. Edwin Portman is a very competent person; that he is an experienced gardener; that he can direct horticultural experiments; prepare show schedules; write botanical names correctly; lecture on vegetable physiology; tell the amount of heat that will be generated from a given quantity of four-inch pipe by a ton of Wallsend coals; and he may be able to recover the Society from its present difficulties; but that is not the point. The office ought to have been thrown open, and the best man chosen from among the candidates, of whom the Hon. Edwin Portman might have been one, and if he were the best, the Fellows of the Society would have known it.

Yet we feel justified in stating that the horticultural horizon begins to brighten. We believe this season will see an indication of a desire to do something for pure horticulture. Already a committee has been appointed for the direction of Chiswick Garden, from which we presume it is to be restored to its former attractiveness, and gardening experiments are to be carried on in such a way as to give evidence that practical horticulture is not any longer to be neglected. With such men as we hope to see elected at the next annual meeting, and with those of the former Council who remain, we feel sanguine for the future; but that feeling will only be indulged in so long as we know that the Society is governed by a horticultural Council, and not by a non-horticultural dictator.

FLOWERS OF THE PAST SEASON.

ROSES.

WERE I to be asked my opinion of those charming young *débutantes*, Lady Cicely Crinoline or Miss Clara Montgolfier, my answer would materially depend upon the time of the year when I saw them. If when their mammas (with as much care as John Scott would

exercise on the training of a young filly), had managed everything so that they should make their appearance under the most favourable circumstances, with all the freshness and hopefulness that a hitherto untried but tempting field encourages, I should probably pass a very different estimate of them to that which I should do when, after the fatigues, excitements, and follies of a London season, they were trotted out for inspection. With the bloom all off, the used-upness most manifest, they would seem very different creatures to those who sparkled and shone with such brilliancy at their coming out. None the less different are those charming *débutantes* with such high-sounding names who cluster round the queen of flowers, and every year, we are told, are more beautiful, finer, and more superb than any of their predecessors. I have seen them in their native freshness, seen them as they grew in the raisers' ground around the fair city of Paris; and I have seen them afterwards when, forced in unnatural atmospheres, cut, hacked and hewn, budded, grafted, and what not, they have thrown out a bloom or two as indications of their beauty; and I have involuntarily exclaimed, "What! That used-up, pale-coloured, flimsy-petalled flower, the same ravishing beauty I saw before it came out! Why! there was that Bourbon Rose named after myself. I saw it at Margottin's—a fine, well-coloured, good-looking flower. I saw it several times this season, and I declare I felt like the little old woman in the nursery song whose petticoats had been cut short by some malicious wag, "It surely can't be I." I unhappily keep no dog, or I might have applied the same comical test she did. And hence one has to speak very doubtfully of the new Roses. Even after one season of trial we see but few of them in their normal condition, and very few of our finest Roses have won a name for themselves the first season. Hence in the remarks I make on those I have seen this past year I may, for all I know, be very far out, but at the same time it is the only chance one has of seeing them. I have already in a general way expressed my opinion upon them, and shall now go a little more into detail. Many I have not seen—indeed, there are many which I very much question whether they ever find their way over here in any shape; while we know of many that do that their owners would heartily wish back again in "their ain land."

*Alpaide de Rotalier*.—I have seen this but once, and then I thought it would be a useful flower. The colour is a clear rose with a satin-like gloss; the shape excellent.

*André Leroy d'Angers*.—A seedling of Trouillard's, Leroy's foreman, and in the possession of Mr. Standish. It is a very rich dark velvety purple. I may be too fastidious, but I should say another row of petals would be a great improvement. It will, I am sure, be a useful Rose.

*Bernard Palissy*.—A very fine Rose, and, I am sure, likely to prove a favourite with exhibitors. It is a seedling from Jules Margottin, but not of the same shape as that flower, being flatter or expanded. The colour is a bright reddish carmine, and the growth all that can be desired.

*Duchesse de Morny*.—Undoubtedly one of the best Roses of the year; the colour a fresh pale rose, reverse of petals silvery. The shape is excellent, well cupped; the flowers large and double, but not too much so for our climate.

*Claude Million*.—I saw some good blooms of this at M. Eugène Verdier's in June last. It was there a well-cupped, imbricated, scarlet-crimson flower, and I have heard a good report of it from one or two growers here.

*Kate Hausburg*.—I saw a very nice bloom of this at Messrs. Paul & Son's at Cheshunt in the autumn. The flower promised to be large, colour clear rose. The plant appeared to be very vigorous.

*Eugène Verdier*.—A deep violet-purple rose, of excellent form, and likely to be an acquisition. This I also saw in bloom in Paris, but it is a Lyons flower.

*Madame Derreulz Douville*.—I see that this has not found its way into some catalogues, and yet I am convinced that it will be one of the best Roses of the year. I saw a bunch of its blooms at Levéque's (who let it out), and it was then very beautiful; the colour a bright pink or tender rose.

*Madame Victor Verdier*.—Undoubtedly one of the best of the year. I have seen some truly grand blooms of it. It is one of the very deepest Roses in build, not colour, that we have; and although the colour is of that bright cherry red

of which we have so many, yet I believe it will be a general favourite.

*Maréchal Forey*.—One of the few indifferent Roses that Margottin has sent out, and so I told him when I saw it in bloom in his garden. He was constrained to acknowledge that it was good for effect. Alas! effect is nothing to us over here unless there be shape, or colour, or both.

*Pierre Notting*.—Another Rose that will stand, I believe, all with exhibitors and growers generally. I saw it at Cheshunt and at Mr. Hedge's; it was a fine, a very fine Rose, blackish red, full, deep in build, with large petals, well imbricated.

These are all that I have seen, and, therefore, all that I can speak about. I have heard others praised much, such as *Amiral La Peyrouse*, *Maréchal Souchet*, *Souvenir de Maréchal Serrurier*, *Paul de la Meilleray*, *La Reine de la Pape*, and *Baron Pelletan de Kinkelin*, but it is all hearsay; and I know how much individual tastes have to do with judgments in flowers, and therefore decline to "follow my leader" in this matter. All the Roses I have described have one quality without which I do not think any Rose ought now to stand a chance of being recognised as a desirable novelty—I mean vigour of growth. I am also inclined to agree with Mr. Perry that they are more deserving the name of Perpetuals than many of their predecessors; and what a pleasure it is to find, as I did to-day (January 11), on looking round my little plot, a really good Rose to be gathered and fit to place in a vase in the drawing-room. The last Rose of summer is a myth now, thanks to the Hybrid Perpetuals.

Before leaving this chat about new Roses, I may mention that I received the other day two plants of a Rose which will be I am sure, if true to its character elsewhere as it is in Devon, a great acquisition—I mean a *climbing Devonensis*. It is a sport which has been fixed by Mr. H. Curtis, of the Devon Rosery, Torquay, a name dear to every lover of the queen of flowers. The shoots on these plants were long and vigorous; and Mr. Curtis says it is equal in vigour to *Gloire de Dijon*. Should it be so generally, it will doubtless prove to be the best white climbing Rose we have.—D., Deal.

#### EFFECTS OF HORTICULTURAL EXHIBITIONS.

Now that horticultural exhibitions are over for the season of 1864, it may be considered neither edifying nor interesting to refer to the matter in a spirit of inquiry or discussion. This may be true as regards the season that is passed, but not so as respects that which is to come. The majority of plants, indeed, are at rest, and the stoves and greenhouses of exhibitors present an appearance that would, to the uninitiated, afford no indication of the splendid productions that grace the summer shows. Many people who admire the products of the greenhouse, the vinery, and the stove, but have no definite idea of the manner in which they are brought to perfection, would, probably, be much surprised could they see many of the places in which they are grown. The first impression would doubtless be that their care had been abandoned, or, at least, that no great efforts were being made for the following season. The majority of plants, I have said, are at rest, but the plantsman must know no rest beyond what is absolutely necessary at this or, indeed, any other period of the year. There must be careful and continued watchfulness. Silently and surely the work is progressing, and by-and-by the result will be seen. It is during the months of the winter and the opening days of spring that the exhibitor is earning the credit and applause which in the summer, if successful, he receives.

Now the reason many gentlemen object to their gardeners exhibiting is that all the energies of the latter are directed to the production of subjects for exhibition, and that at other periods of the year there are no flowers worth looking at, or fruit fit for the table. In a great many cases this I know to be true; but then there are some in which it is otherwise, and the above objection does not hold good. In such cases the energies and perseverance of the gardener are creditable, the more so, as they prove the fact that a man may be allowed to exhibit as an advantage to himself, and still keep in view the wishes and interests of his employer. On the other hand, I have known gardeners who appear to have no

desire to exhibit, simply because there is then nothing to take their attention off the place under their charge, and they are, consequently, able to keep everything in perfect order and neatness. I have lately seen a place where the gardener appears to entertain this view, and nothing could be prettier than the conservatory, nothing in more perfect order than the vinery, and, indeed, the whole garden generally, showing that the gardener possesses those qualities which are calculated to give satisfaction to his employer. There were no grand specimen plants in the conservatory, such as go towards making up an exhibition; the plants were mostly small, but clean and healthy, and tastefully arranged, showing they were in the hands of a clever plantsman, one who evidently could if he wished grow good specimens.

Now the question I would ask is, Were such men as he to exhibit would their employers be subject to any loss in consequence of the gardener's attention being too much directed to that particular object? There can be no doubt where a man shows superior taste and cleverness in growing plants to gratify his employer, that the same man would exercise the same qualities in growing them for public exhibition. In the case of the gardener his merit would become known and appreciated by a much wider circle, while his employer would probably be highly gratified. Nor do I believe that the interests of the latter would suffer in the least; for a gardener who is desirous of doing himself credit in a small way, where only his employer and friends can appreciate his endeavours, is not the one to slacken his exertions when he becomes better known. I have no hesitation in asserting that far from any loss resulting to the employer, the gain would be mutual. For the sake of illustration I will suppose that a gentleman, interested in gardening and plant-growing, engages the services of a man who is represented as being well acquainted with his business. This man shows a peculiar aptness for growing good specimen plants or fruits, and is desirous that the public should see and appreciate them. There may be some demur on the score of injury to the plants or fruit exhibited, but if carefully managed this need not be an obstacle, and the advantages outweigh all that can be said in opposition. The gardener obtains much credit, and derives some pecuniary benefit, while the master gains the reputation of being a patron of horticulture, and of encouraging a useful and scientific pursuit. There are, it is true, some men who are so careless as to bring home their plants in a woeful condition, and some, too, who regard a show-day as one on which they are bound to enjoy themselves to the utmost, and forthwith imbibe stimulants more freely than is necessary or advisable. Their plants, consequently, suffer injury to an extent that would justify gentlemen in refusing to allow their gardeners to exhibit; but such, I trust and believe, are exceptions; for men who can and do persevere in a business requiring such careful watching as plant-growing, are not and cannot be habitually given to stimulants. The mere fact of their success will generally be a sufficient guarantee for their sobriety.

Presuming that the question of allowing gardeners to exhibit is one of interest among employers, and knowing that THE JOURNAL OF HORTICULTURE has been a medium through which the subject has been agitated, I do not consider it out of place to renew the discussion. My own opinion is, that where employers are liberal, gardeners careful, and exhibitions managed on correct principles, they are beneficial to employers, to gardeners, to the public generally, and to the interests of horticulture in particular.

In speaking of the liberality of employers I do not mean to imply that they should be always buying plants and spending large sums of money. It is a mistake to suppose that anything of the kind is necessary to exhibiting; for it often happens that one gardener, though ransacking every nursery in search of good things, as gardeners say, yet produces no good specimens, while another, who is content to do the best with what he has, does himself infinitely more credit by doing what he does well. What I would imply is that liberality of spirit which, allowing a man to understand his business fully, leaves him to manage it in his own way, untrammelled by doubts and fears, or requirements that operate as a clog, and make his situation one of extreme difficulty. That such is often the case I could call numerous witnesses; and although it may arise simply from want

of thought, still where a gardener is left entirely free, an otherwise difficult situation becomes comparatively easy.—F. CHITTY.

#### HARDINESS OF JAPANESE CONIFERS.

WITH reference to Mr. Robson's article respecting *Retinospora obtusa* turning yellow, I have to state that in the spring of 1863 my employer purchased a plant of each of the *Retinosporas*, also a plant of *Sciadopitys verticillata*, not knowing at that time if they were perfectly hardy. The following winter I placed them in a cold frame, where they could be protected from severe frost. Last autumn I planted them out in a bed composed of peat, sand, and loam. The *Sciadopitys* commenced turning yellow after the first frost, and had to be taken up again; but the *Retinosporas* are quite green, especially *obtusa*, although they have been exposed for several nights past to 12° and 14° of frost, which speaks well as to their hardiness.—E. WELCH, *Palace Gardens, Armagh, Ireland.*

#### CULTIVATION OF THE MELON.

(Continued from page 29.)

TEMPERATURE.—The next point of Melon culture relates to temperature, both top and bottom. The former should be equally maintained at one point day and night; the latter should be hotter by day than by night, so as to imitate as much as possible a natural atmosphere, subject to conditions essential to the cultivation of the plant in an artificial climate. The cultivator should bear in mind, that though a certain temperature is required to grow any fruit successfully, forcing should be influenced or governed by the external climate in which the artificial one is maintained. I allude to early forcing, when dull cloudy weather chiefly prevails, and when to maintain a high day temperature equal to that on bright days would be absurd, because it would be wasting the energies of the plant and causing slender imperfect growths. During severe weather it is equally wrong to act independently of external influences; for though Melons are natives of hot countries, yet in such extremely high and extremely low temperatures occur, the hottest days being followed by the coldest nights—that is, the most sunny days are the hottest, and the nights colder in proportion than when the days are cloudy. Small as these matters appear, they exert a great influence on vegetation, and no one can cultivate plants successfully without a knowledge of the laws that regulate the growth of vegetables. These are so clearly explained in the "Science and Practice of Gardening," that there can be no excuse for those who do not know why certain operations in the art of horticulture are needful.

At planting, and for a short time afterwards, it is desirable to maintain a rather high temperature both top and bottom, in order that the plants may be quickly established. To determine the degree of bottom heat a ground thermometer is a more certain and accurate means than feeling a trial stick. Such thermometers can now be had cheaply, and should be thrust in so that the bulb may be fully 6 inches below the surface. The readings should be from 80° to 85° for the first fortnight, afterwards they should be as nearly 80° as possible; and if the temperature be kept steady at that, and not lower nor higher than 85°, it could not be better suited for the Melon in any after-stage. The top heat for the first fortnight should range between 70° and 75° by night, with a rise of 5° on sunless days, 10° on those which are alternately cloudy and clear, and of 15° on clear days. After the plants have become well established the night temperature may sink to 65°, which should be the minimum; for though a night temperature of 60° will not have any evil effect on the well-being of the plant, yet that point should be attained but seldom, and then only when the house is first entered in the morning, which will be at 6 a.m., or soon afterwards. The fire should then be set going gently, so that by eight or half-past eight o'clock the thermometer may indicate 70° in a dull morning, 75° on a bright morning, or even 80° if the morning be mild and sunny. The fire may then be kept gently burning, so as not to allow the temperature, whatever it be, to sink, but, on the contrary,

to keep up that attained, and afford another rise of 5° by 1 P.M. The fire may then be made up, so that it will not increase the temperature, but allow of its sinking, which it will not do for some hours, in consequence of the heat radiated from the medium furnishing it; but towards night the temperature will begin to fall, as it ought, the fire only being used to prevent its sinking too low during the night. A little practice will soon enable any one to understand and manage this. These conditions of temperature are to be maintained at all stages of the growth of the plants, except when the fruit is ripening, when a higher temperature may be given with more air, as heat with light and air hastens ripening and heightens the flavour.

It sometimes becomes necessary to give more heat than above recommended in order to obtain fruit earlier, or by a fixed time. In this case the temperatures named may be increased 5° throughout; but this should not take place until the fruit is set and swelling, for to force earlier will result in weak growths, indifferent setting, and, of course, inferior fruit. If a plant is forced into an early maturity it cannot produce fruit equal to that obtained by a more natural system.

**AIR.**—I need scarcely say that air should be given on all favourable occasions, and a little will always be beneficial, even if a rather stronger fire be kept up to permit of its being given. There is no better rule than to admit air as soon as the thermometer indicates 80°—not too much all at once, for that may cause a reduction in the temperature, which never ought to take place—increasing it proportionately with the increase of temperature, or reducing it as the temperature declines. It should be given so that the temperature may increase, at all events be maintained, and not reduced by it, for that would be stimulating the plants one hour and causing a stagnation the next. Whatever amount of air is given, it should be reduced before the temperature is much decreased, it being advisable to shut up with a temperature at least 5° higher than when the lights were opened, or at 85°. This is trapping the sunbeams, or admitting them by opening early, and closing early in the afternoon in order to shut in as much of the sun heat as practicable. So long as the proper degree of heat is maintained it is impossible to give Melons too much fresh air; but in admitting it care should be taken to avoid cold draughts.

**MOISTURE** is most important in Melon culture. If the plants have too much they become gross, the fruit is watery and insipid, and, if the atmosphere be surcharged with it when the fruit is ripening, the latter is not only poor-flavoured but frequently cracks; if, on the other hand, there is a deficiency of moisture, the foliage is soon rendered a suitable prey for thrips and red spider, the fruit is small, and the duration of the plant short. Either extreme should therefore be guarded against. From the time of planting to that of the flowers opening the soil should be kept moist; it should not be sodden with water nor the plants allowed to flag for want of it. It should therefore be kept moist, or neither wet nor dry, yet it should not be kept so by dribblers, but by copious waterings at intervals of once or twice a-week, as the aspect of the soil itself indicates. The soil should likewise be moist when the fruit is setting, only water must then be given so as not to wet the surface until the fruit is set. After this the soil should be kept moist, quite as much so as for Cucumbers, in order that the fruit may swell freely. This watering will usually be required about twice a-week—from the time when the fruit first fairly commences swelling to that of its netting, though the frequency of watering depends on the growth of the plants and the quantity of soil they grow in. When the borders are but narrow and shallow it may be necessary to water more frequently, and, instead of using clear water, weak liquid manure may be applied; but unless given by a practised hand it is best let alone, otherwise too strong a dose may cause irretrievable loss. Those not experienced in such matters would do well to make their liquid manure by dissolving one ounce of Peruvian guano in a gallon of soft water, and apply it at every alternate watering. A much better plan than employing any liquid manure is to mulch the surface of the borders, after the fruit is fairly set and swelling, with an inch or so of cowdung six months old, with the short manure coming from an old Mushroom-bed,

or in the absence of either of these with stable-manure. With this on the borders, whenever water is given enough of the nutritive constituents are washed down to the roots, and the supply is not excessive because only a small portion of the fertilising agents is washed into the soil at each watering. When the fruit begins to net the watering should be gradually reduced in about ten days to one half, after which it will suffice if the soil be kept only just moist until the fruit is ripe. All waterings, whether with water or liquid manure, should be of the same temperature as that in which the roots are situated.

Atmospheric moisture is another important agent in Melon culture. It is maintained by sprinkling the walls, paths, &c., and by having receptacles for water or gutters on the heating surface. When there is a tank, some part of which is open or communicating with the atmosphere through openings that can be regulated at will, the guttered pipes are not required; but when these conveniences do not exist, a row of guttered pipes along the front of Melon-houses, or, in fact, all houses that are required to be kept at a high temperature is beneficial, by maintaining a uniform degree of moisture. When there are such contrivances the necessity of frequent syringing is to a great extent obviated, and on dull days the moisture evaporated from them is quite sufficient without syringing; also, when the fruit is setting, during the early and late periods of the year, and when the fruit has advanced towards ripening. The evaporating-pans or gutters may be allowed to become empty when the fruit is ripening. In addition to the moisture obtained by evaporation from the troughs, gutters, or tanks, a gentle syringing of the plants, especially on the under side of the leaves at the time of shutting up the house or a short time afterwards, will do much towards checking the attacks of red spider and thrips, and is necessary to keep the plants healthy. On fine mornings every available surface may be sprinkled with water, and thus with the aid of the other evaporating surfaces sufficient moisture will be afforded the Melon in all its stages. No syringing overhead takes place at the time of setting, nor when the fruit is far advanced towards ripening.

When there are no evaporating-gutters or troughs, the syringe plays an important part in Melon culture in houses. During bright weather the plants should be syringed at shutting up, or not later than an hour afterwards, directing the force of water as much against the under side of the leaves as possible, and taking care to wet the stem for about a foot from the soil as little as possible. On bright mornings syringing should be repeated in the same way before 9 A.M.; but on dull days sprinkling the paths, walls, &c., will be sufficient, and in the afternoons of dull days when no air or but little is given, a sprinkling of the paths and walls will raise sufficient moisture without syringing the foliage. This syringing must be kept up at all times, subject to the conditions already mentioned, except when the blossoms are setting, at which period sprinkling twice a-day without syringing the foliage is desirable, and when the fruit begins to ripen, or after it becomes fully netted over, syringing must be discontinued, and sprinkling also when the fruit commences ripening.—G. ABBEY.

(To be continued.)

#### NEW FRUITS OF AMERICAN ORIGIN.

THE following extract from the proceedings of the American Institute Farmers' Club of December 6th last is of interest, as relating to a variety of Pear which has already received the stamp of approval from nurserymen in this country as quite worthy of a place in a select catalogue of English fruits:—

"A New Winter Pear.—Wm. S. Carpenter placed upon the table specimens of a new winter Pear, sufficient to give every one present a practical test of its quality. It is in colour yellow russet, in size and shape not unlike the Seckle. It is in good eating condition from this time until February, according to the method that it is preserved. It is deliciously sweet and melting to the taste, and it was pronounced by a unanimous vote of the Club the best winter Pear known. A bushel of this variety is now on exhibition at the rooms of the Institute for the Greeley Prize of

100 dols., and we shall be surprised if it does not gain the award of the committee. Mr. Carpenter stated that the Pear was known as Dana's Hovey, and called upon Mr. C. M. Hovey, who was present, to state how it originated.

"Mr. Hovey stated that the opinion had prevailed for a very long period that seedlings produced by planting the best known varieties of Pears always tended back towards the wild stock; hence the neglect of nurserymen to plant seeds, and the efforts made by Van Mons and Knight to obtain new varieties by hybridising and impregnation. Of the ten new sorts produced by Knight, which are considered good in England, only one, the Dunmore, is excellent here. Nature and accident have given us better sorts—witness, the Washington, Sheldon, Seckle, &c. These accidental seedlings certainly did not go back. Mr. Dana, of Roxbury, having determined to attempt to produce new seedlings, planted seeds of the Seckle, Beurré Diel, the Bartlett, and others of the best varieties he could obtain, and the result was that he got six excellent new Pears. This on exhibition is one of the number. It was first brought into notice in 1854, and known as No. 16. It was pronounced so remarkably excellent by the Massachusetts Horticultural Society that Mr. Hovey purchased the original tree for the purpose of propagating from it. This is the first year in which he has obtained fruit to any considerable amount. One of the peculiarities of this Pear is that it never rots from the core, but, like the Apple, decays first upon the surface. The bearing quality of the tree is as good as the Buffum. It has somewhat the habit of the Seckle, but this tree is more vigorous. It has thick, heavy foliage, and no disease. The fruit is about the average size of the Winter Nelis. The tree grows well both as a standard and dwarf. Mr. Hovey exhibited another Pear called the Caen de France, which was introduced to this country from Van Mons in 1835, and is still very little known. It is much better than the Winter Nelis, and twice as large. It has one fault—it is slow to come into bearing."

To the reader of gardening periodicals published in the United States, or even of the newspaper press of that country, it must have often occurred how very far in advance of us our transatlantic brethren are in the pursuit of pomology as an art. We may, or may not, excel them in the scientific accuracy of our experiments; but the intense interest manifested in the production of new varieties, and the accurate mapping out of the districts where such and such first-class sorts may be grown in perfection, accomplished through the medium of their numerous pomological societies, betoken a more widespread sympathy with fruit and fruit-growing than we find amongst ourselves. Much of this is attributable, no doubt, to the fact that in even the Northern States the average maximum temperature of the summer is never so low as to endanger the quality, and in particular the flavour, of our commoner fruits. Americans, at least in the cities and their neighbourhood, are large consumers, and, therefore, large producers of fruit. In the hot days of their hot summers the Strawberry, Blackberry, Raspberry, and Peach are welcomed by thousands in a way that we, in a milder climate, can form little conception of; but even in the depth of winter, when the thermometer sinks again and again to zero or under, the Apple is a household fruit long after it has disappeared from most English desserts. Had we the comparatively cloudless sky of the States, and the consequent improvement in the flavour of our fruits, the Apple and Pear would more frequently than at present form a reality on our tables at every meal, to the manifest improvement of our health, instead of being only produced at dessert as a provocative to appetite at a time when all the digestive powers have already exclaimed, "Enough!"

One advantage America possesses is the evident facility with which good new varieties are produced compared with the reported paucity of their production among thousands of seedlings here and on the continent. Somehow, it would seem the sporting of the Apple in the United States, after its introduction from Europe, took entirely new and very favourable directions, resulting in at least one quite novel strain, to which we have nothing approaching among the Apples of Europe. It is worth the attention of pomologists to ascertain whether, by subjecting fruits in their growth to occasional outrageously artificial conditions, some out-of-

the-way sport might be induced in the seedlings produced from them. May not orchard-house fruits work wonders in this way?

From Australia, I have no doubt, we shall ere long have some splendid acquisitions in new seedlings, the result of the climate our English fruits experience there; but there is a melancholy certainty that not a tithe of them will reach perfection in the average of our summers. After all, it is on ourselves we must rely.

A seedling fruit society seems, to me, to have a very clear and important mission marked out for it, and only requires six hearty lovers of good fruit, who are willing to spare a little trouble, to set it a-going. I feel sure the results of a very few years would abundantly reward all who helped the good work forward. A Ribston Pippin in May, a Marie Louise for the warm days, that will at times make us long for early Strawberries a full fortnight before they are comestable at even 2s. a-quart!—these, or something quite as good, are perfectly within the reach of careful seed-sowing, and patient waiting for results. This work must be gone into some day, and why not in this good new year as well as any other?

A very interesting paper might be written on the contents of an American fruit-nurseryman's catalogue. There is some well-defined law regulating the changes which varieties undergo when transplanted to new climates; but there is, at first sight, such an admirable confusion in the tricks they play, that it will be long ere anything to be depended upon in the way of explanatory theory will be evolved. Indeed, I question much if it would not be profitable for each country to exchange with the other all the seedling fruit trees which had, in the respective countries, been proved to be thoroughly useless. I am confident that each would find some first-rate prizes among the other's rejections. Why should Sturmer Pippin and Herefordshire Pearmain be welcomed in the United States as first-class for the dessert, whilst Kerry Pippin and Golden Reinette are rejected as almost worthless? Even the Ribston and Golden Pippins are only very inferior in New York or Ohio, and Marie Louise scarcely worth growing.

To a lover of good fruit it is pleasing to trace the origin of valued varieties to their source, and year by year we are adding a few to those we may thank our American cousins for. Our own Peaches and Cherries bid fair to be half supplanted by the new importations, but to our lists of other fruits the additions from that quarter are only few. In Pears the Seckle is the only one that has as yet received a first-class certificate from the English fruit-grower. In Apples we have Early Harvest, Mother Apple, Franklin's Golden Pippin, Northern Spy, Melon Apple, and perhaps a few others. In Plums we have Jefferson and several other first-rate sorts. In Gooseberries we are unrivalled by the produce of either the continent or the Western hemisphere; and, therefore, by a strange confusion of thought, similarly exercised in relation to other things than fruit, pass scornfully by what we should rear very delicately were they not so thoroughly un-aristocratic as to grow quite delicious without other help than the summer sunshine, strained to dilution through our own dull atmosphere. I have seen and heard a good deal of Black Hamburg Grapes, but have yet to feast my eyes and taste upon any that shall half reach the excellence of the produce of some very plebeian Gooseberry bushes within view from my window.—  
FRUIT-EATER.

### LILIUMS AND GLADIOLUSES.

A COMMON mistake in the culture of Liliams is putting too many in one pot. I was struck with an article by one of your contributors, in which he recommends about half a dozen to be put in one pot. I smiled when reading it, for I gave up this practice some years ago. In a 10-inch pot I rarely put more than one bulb, and in a No. 4 pot two, and these I plant in a compost of one-third good sweet dung (if a few old dry "cow patches" are to be had all the better), and two-thirds new soil, with a sprinkling of sand. I plant at different times, as recommended by another correspondent, to insure continuous bloom, and water with liquid manure weekly after the leaves show above the soil. I think the bulbs should be planted at least 2 inches

below the surface. Any spare bulbs I plant in good ground in the open air, and by putting 5 or 6 inches of soil over them I do not find the frost injure them.

At Ashton-under-Lyne, where we certainly can grow Lilliums and Gladiolus well, I have seen scores of Lilliums with from ten to eighteen flowers on a spike. I had last summer, in the conservatory, spikes thicker than my thumb, with from twelve to sixteen flowers on each; but almost everybody here believes in treating these bulbs the same as if they were growing a large Cabbage—viz., plenty of room and good stuff for them to feed on. My stock of Gladiolus consists of about fifty-eight sorts, but Mr. Tipping, an old amateur florist, has upwards of one hundred, and well indeed he grows them. As to his practice, I cannot speak further than that he feeds them well. My own practice is to give them plenty of good manure. To two beds 7 yards long by 2½ broad, I this year added to each two good barrow-loads of old Mushroom-bed mould and one bag of cocoa-nut fibre, and worked the whole well with a four-tined fork. The dung from the Mushroom-bed I allowed to lie on the bed to sweeten for some weeks before it was worked in. I invariably plant my bulbs in pots about the middle of March, and use 24's or 32's. This year I made a compost of cocoa-nut fibre, new soil, and well-sweetened dung, in equal quantities for planting them in. This way of growing the Gladiolus of course finds me plenty of work, and in the present year I intend to plant as soon as possible in the open ground some of every sort that I have plenty of. I transfer the potted bulbs to the open ground in May. By the above mode of starting them they flower sooner, for many of the sorts would scarcely throw up their bloom-spikes before the season was too far gone. I wish our cross-breeders could obtain a race possessing the hardness of Gladiolus communis. I have probably upwards of a thousand bulbs of that sort.—JOHN HAGUE, *Ashton-under-Lyne*.

#### PRODUCT OF POTATOES.

I THINK Mr. Abbey could hardly have read my former communication with sufficient attention before commenting upon it, or he would not have so much misunderstood its purport. In these days of rapping, table-turning, the Davenport Brothers, Professor Pepper's ghost, and divers spiritual and other manifestations and delusions, I do not know that I am not to assume it as a compliment when he seems to suspect me of being of a somewhat incredulous turn of mind. I beg him, notwithstanding, to believe that I am not incapable of accepting facts on trustworthy evidence. I freely accept the forty-fourfold return of "W. W. H.'s" blue Potato, not exactly by reason of Mr. Abbey's argument, but because "W. W. H." assures us there was no error, and you, Sir, vouch for his responsibility. I accept also as fact Mr. Abbey's correspondent Mr. Lupton's two wonderful roots of 43 lbs. and 41 lbs. respectively, simply because I have had credible information of a still higher result than either.

But all this has not the slightest bearing on the drift of my observations. Certain experiments were published in your Journal by "W. W. H." which gave an enormous superiority of productiveness to a certain seedling Potato. I forwarded to you another set of experiments made with great care and accuracy on a larger and, as I thought, therefore a more reliable scale, wherein the same seedling stood much below some older sorts, and below other seedlings of the same growers, in which respect they coincided with some experiments published by those growers themselves. My sole object was to show that Paterson's Irish Blue was far from always maintaining the superiority attributed to it. I ventured also to express my opinion that some error might have arisen from this circumstance, that on the data before us the produce ascribed to these Irish Blues was at the rate of more than 50 tons per acre.

Now Mr. Abbey seems to impugn, I will not say the fairness, but the propriety of my adopting this assumption on two grounds—because I do not say what precise distance is meant by the words "ordinary distance of sets," and because I do not, any more than "W. W. H." or "UPWARDS AND ONWARDS," give the weight of the sets. If Mr. Abbey had given my observations more than a cursory glance he

would not, I feel sure, have said this. I did give the weight of the sets, and if he had continued his own quotation from my letter, "The quantity of seed for an acre at the ordinary distance with rows 3 feet apart, &c," only three words farther; if the "&c." had been made to follow instead of go before the next three words "is, we see," he would not have failed to observe that I had precisely stated in the table above the weight of the sets used, to which the words "we see" (the quantity being then repeated) were an unmistakeable reference.

I omitted to specify what I considered the "ordinary distance in the rows" to be, because it was not necessary to my argument to specify it. The quantity of the ground and the weight of the sets being given, nothing more was required to show that a forty-fourfold return would give upwards of 50 tons. I am not aware that it ever for a moment entered into the head of any one of us to inquire, as Mr. Abbey imputes to us, "what kind of Potato gives the greatest yield from the least seed," instead of the greatest yield from the same ground. Neither can I see anything in "W. W. H.'s" letter or my own which should lay us open to such imputation.

As to the suggested possibility that one quantity of these sets might all weigh 4 ozs. each, and the other all 2 ozs. each, I am sure Mr. Abbey will excuse my entertaining the question. The sets in both instances were had from Messrs. Paterson themselves, and there is not the slightest ground for believing they differed on the average. If "W. W. H.'s" 14 lbs. of these sets had occupied a much larger space of ground than the rest there cannot be a doubt he would have said so. In the absence of anything exceptional being stated we can reckon only by the conditions before us. We may abandon forming conclusions altogether if we must first admit into our premises every possible variation the imagination can suggest.

When Mr. Abbey says "Experiments of this kind are apt to lead to an incorrect conclusion when the produce per acre is calculated by the produce of a certain weight of sets without stating the extent of ground occupied by them," he states the exact contrary of my statement, but he takes up precisely my position. I hope he will allow me to point out to him that this is but a repetition of my own observation when I said "The only reliable comparative results from experiments of this kind would require not only equal weight but equal size or number of sets," the number of the sets of course determining the quantity of the ground. I would beg leave again to add "The larger the area the nearer the approximation to truth." In fact I think so little can experiments on a small scale and under exceptional circumstances be relied upon, that even the two monster roots grown by Mr. Lupton do not flatter me with hopes of 50 tons per acre. Certainly Mr. Abbey's other averages do not encourage the expectation. Still experiments of this kind are very valuable if they are conducted with accuracy, several times repeated, and conclusions from them not pushed too far. They may then often lead to useful results. They might, for instance, unravel one important point to which Mr. Abbey adverts—the distance at which Potatoes may most productively be set. For myself, I have been for some time of opinion that if we are to make any nearer approach to the 50 tons per acre it must be in the direction of Mr. Lupton's experiments detailed by Mr. Abbey. For several years I have grown my garden Potatoes in something approaching that style of cultivation. I borrowed the idea from a practice I observed in parts of Cheshire and Shropshire, where it is called clumping. Each clump occupies a square yard of ground. The set is placed 2 or 3 inches above the level of the soil, and on whatever manure is used. A mound of earth is raised over it. When the stems are about 8 inches high they are bent down gently, and retained in that position by a covering of soil. As the growth proceeds more earth is added, and the clump enlarged. On this plan I have invariably had larger Potatoes and a better crop from the same seed than from rows at any distance, and I have always found them prove free from disease. The tops of the mounds are never overshadowed by the foliage, but are freely exposed to the action of sun and air, from which I assume the chief benefit arises. As yet I have myself tried the system only in my garden, but they grow Potatoes thus in the field in the counties I have

named, and, I have been assured, with advantage. In the next season I intend to test the plan in field culture against the ordinary rows. The calculation, of course, is whether the diminished number of roots and some increase of labour will not be more than compensated by the more abundant crop. The quantity of seed saved would go far I apprehend to pay the extra labour.

In one respect Mr. Abbey will, I am sure, agree with me—viz., that the free discussion of this and similar topics is not an unimportant step towards further progress.—  
AGRICOLA.

### MORE ABOUT POTATOES.

I HAVE been asked whether I consider Mr. Hogg's Coldstream Potato suitable as an open air variety for garden culture, as well as for an orchard-house? I reply, that if I consider it eminently suitable for orchard-house culture, I consider it pre-eminently so as an early garden variety. In fact, my chief trial with it was in that way, for it would never do to keep it growing in an orchard-house so late as the 19th of July, the period I stated I had taken it up. When I mentioned that date I concluded that it would be understood to refer to the open ground. I intend for the future to confine my first earlies to the orchard-house, as being a more convenient and interesting mode of culture than growing them in a frame; but there is no royal rule for planting Potatoes. I daresay there never will be.

As regards the omissions complained of at page 10, I cannot suppose that Mr. Abbey would care to bear in memory what I write, so I must beg to state, that I have met his views several times over in my papers on the cultivation of the Potato, and to repeat, that for the open ground, I give 36 inches between the rows of early Potatoes, and 42 inches for the late sorts. The sets of the former I prefer to weigh from 2 to 3 ounces each, and those of the latter from 3 to 4 ounces—viz., medium-sized old Potatoes. The distance I allow between each set, judging as I plant them, according to their size, is for the early varieties from 12 to 16 inches, and for the later sorts from 15 to 20 inches. Results by weight, measurements, &c., for the system in which I grow Potatoes, sufficient to suit the customs of most localities, can be found on referring to Nos. 48, 90, 100, 140, 141, 163, and 164. Of late years, in order to arrive at just conclusions, I have not deviated from my method of planting, and also for the very satisfactory reason that the plan suits me well.

The mere coddling of a few sets in very rich soil to produce a large quantity of, possibly, uneatable tubers, merely "to astonish the natives," or for exhibiting purposes—albeit, praiseworthy, is no example to be followed in general cultivation. My advice is given to work for a crop, to grow as many Potatoes as possible upon the ground for years in succession, and for the tubers to be good flavoured and good favoured.

The result of Mr. Francis Lupton's experiment is very interesting, and I am glad Mr. Abbey has put it on record. Amongst some notes I took at the Royal Horticultural Society's Show on the 7th of last month, which I now take the opportunity to send you, is an account of another extraordinarily productive root, of what I will call a Brighton Regent, as it is in form exactly like some Potatoes I brought from thence into this county nine years ago, where it has held its ground amongst the cottagers ever since.

"Report on the growth and produce of a single Potato grown at the establishment of Messrs. Spary & Campbell, Queen's Graperies, Brighton. The tuber from which the plant was produced weighed 2 ounces in December, 1863, was planted to the depth of 10 inches at the time the border was manured in the latter end of April, 1864. It presented two shoots above the surface which grew very strong and vigorous through the spring and summer. By October the haulm extended 12 feet in diameter, being rather more than 36 feet in circumference. On the 3rd of December the crop was dug up and produced 268 Potatoes, weight 39 lbs. 3 ozs., or six gallons.—EDWD. SPARY, F.R.H.S."

I take the number of tubers produced by that single root to be the largest on record. The haulm, however, extending over so large a surface is fatal to the largest acreage pro-

duce. Now, Mr. Lupton does not give us the weight of his sets, nor the extent of surface his Potato-haulm occupied, which would certainly be much more than "4 feet distant each way," as he states the stems were brought down and spread out. My Negro root which produced me 16 lbs. of Potatoes, was situated at the end of a row or ridge (a good representation of which is given by "A CONSTANT READER," at page 6, excepting that I finish-off my ridges at planting-time flatter at the apex), and it occupied a square yard of ground, being at the rate of 34½ tons per acre. For the large-topping sorts I drive down some stakes and strain a line or two of tarcord attached to them on each side of the ridges; this keeps the haulm up in the air instead of sprawling upon the ground. So, unless I can learn how many square feet of soil the haulm of the best root of Mr. Lupton's Potatoes spread over, I do not feel inclined to consider the produce of my root of Negro to be beaten per acre. I sent you some tubers of the root, as also some of the Freebearers, Prolifics, Gryffe Castle Seedling, Walker's Regent, and Scotch Rough White, which grew in the same ridge. Their sets would weigh between 4 and 5 ozs. each. I did not weigh them, and they were planted 20 inches apart. A ridge of Fortyfolds came next to them, the haulm of which is moderate and does not require stakes and cord, and then came a row of Sutton's Finest Regent, which did require cords and stakes. I always take care to plant a second early medium-foliaged kind between gross toppers—viz., in alternate ridges, which allows the sun and air to play between the foliage more freely, and as the former are off the ground some weeks before the latter, light is still more freely admitted to the Cabbage tribe in the trenches. On the other side of the Negro ridge, an Asparagus-bed ran its entire length. We are now, and have been for some time using Brussels Sprouts from the trenches, and Broccoli and Scotch Kale are to follow. Turnips are growing on the tops of the ridges where the Potatoes grew, and I anticipate nice boilings of greens from them before long.

Respecting some other noteworthy varieties which I saw at the Royal Horticultural Society's Show, December 7th, perhaps it may prove useful to some of your readers if I say something as to their appearance and desirability, at the same time I leave a large margin for others to differ from me in opinion.

On Mr. James Veitch's stand there was a good collection. The samples were fine, and had apparently been grown in rich dark soil, which tended to add nothing to their appearance. The Prince of Wales, a rather flat pear-shaped Kidney, was a very promising-looking Potato. (In another part of the Show, Mr. Veitch was awarded a first-class certificate for a fine plate of this.) A Dutch Prolific, in form much like the Red Regent, but blotched slightly with white, I should consider an improvement on the latter much-grown variety. The Lapstone Kidney was here very fine.

In Class 4, a Potato gaining a second-class certificate, which deserved a first-class, was named Huntingdonshire Kidney. I proposed to Mr. Daintree two years ago to call his newest seedling by that name, and at a first glance I thought he had done so and sent a sample to the Show; but no, the exhibitor was J. Taylor, cottager, Hunton Bridge, Watford, Herts, and curiously enough I was afterwards informed by a gentleman's gardener who got them entered, that Mr. J. Taylor has a brother living near St. Ives, in Mr. Daintree's neighbourhood, from whom he received the sort. They were in form like a medium-sized, perfect-shaped Lapstone, and on splitting one with a knife every feature of the new seedling presented itself, though since I have become a grower of Potatoes from seed, I am cautious how I conclude that one variety is the same as another from a similarity of tubers. A year's growth side by side might prove them to be different. I thought them the handsomest sample in the whole exhibition.

Mona's Pride, also a Lapstone-looking Kidney, took my attention. It gained a second-class certificate, and was shown by Mr. E. Budd, gardener to the Earl of Darnley, Cobham Hall.

Burghfield, a pear-shaped Kidney, was very fine. It gained a third-class certificate, and was shown by Mr. Lord, gardener to M. G. Thoys, Esq., Reading.

Lapstone Kidney I mention as being the fairest if not the finest sample I ever saw. For form they ran slightly

out, but they gained deservedly a first-class certificate for Mr. Frisby, gardener to H. Chapman, Esq., Sleaford. If Mr. Frisby should see this, might I request him to let us know the description of soil that he grew them in?

Transell's Seedling, which received a first-class certificate, was a handsome, white, round Potato, which I have down in my note-book as a desirable variety; as well as Early Ten-week, a medium-sized round, with a pretty pink eye—one of those firmly-mealy class of tubers, I suspect, so much approved of now-a-days. Both the above sorts were shown in the collection of Mr. Moffat, gardener to Viscount Maynard, Easton Lodge, Dunmow, Essex.

A good stamp of Potato, I should say either for table or cattle, and gaining a third-class certificate, was shown by Mr. J. Masters, West Hill, Highgate. It was unnamed, and in form like Sutton's Finest Regent. I took it for that desirable variety.

Early Frame, not the small Early Frame I remember from boyhood, but a large, rough-jacketed, Regent-looking Potato, was doubtless good either for table or cattle. Although I have partly vowed not to grow this class of tuber any more in this garden, I feel almost inclined in regard to the above, to break my vow. It was exhibited by Mr. J. Veitch, Royal Exotic Nursery, King's Road, Chelsea, and received a first-class certificate.

Morning Star, worthy its poetical name, and quite deserving a certificate. A handsome, medium-sized, round Potato, shown by Mr. S. Westbrook, Abingdon.

Courtenhall Seedling, a flattish-round, medium-sized Potato, and the finest sample I ever saw of Sutton's Early Racehorse, were to be seen at the foot of Messrs. Sutton and Sons' glass case containing seeds, which was a show of itself.

Of the coloured class of Potatoes I at sight singled out as kinds I should desire:—London Red, a self-colour of that hue, round, and medium-sized, shown by Mr. Frisby, gardener to H. Chapman, Esq.; a Bluish-self, exhibited by Mr. R. Heather, gardener to R. Pulford, Esq.; and a new Potato, running out in form from pear-shaped to oblong, and stated to have been brought from Australia, by Captain Walter, and as being a "very prolific, excellent Potato."

The above are what I considered the pick of a very good show—that is, in the way of what to me were novelties; but I shall always consider a show of Potatoes incomplete till we can arrive at some palatable testing process, and I for one do not care ever to exhibit the tuber again unless a cooking process, for new table sorts at least, can be added, and which I hope will eventually be the case, and why not? Fruit is very properly tested for flavour, and of quite as much consequence is it that the Potato should be so also. I know if this could have been done at the Royal Horticultural Society's Show, I should have been there as an exhibitor, and I would have paid our housekeeper's expenses to London in order that she might have been on the spot to have cooked the Potatoes. A leading Society ought to feel sufficiently interested to provide a room, fires, and saucepans, and then the judges would be able to inform the public which sorts were best cultivated for flavour, and most worthy to be grown. The only thing to fear would be, that the judges of the fruit would want the cooking test to be applied in their department also. But be that as it may, it would create in the women an interest to cook our Potatoes well all the year round, when they knew that their science was likely to result in a trip to London. I am certain that no one would be the loser, only, unfortunately, the Council of the Royal Horticultural Society as at present constituted would not feel sufficiently interested, I fear, to entertain the idea.

There were some very fine examples of cattle Potatoes exhibited at the Smithfield Cattle Show, which was a very good one, and one may say of it, that it has safely established itself at Islington for the future. I noted monster Walker's and Dunlar Regents, on Messrs. Gibbs' magnificent stand of roots, and a seedling from the Fluke, having the shape of its parent with a yellow cast of countenance, purported to be grown by F. Murton, Esq., Ashford. There were also two other Fluke seedlings suitable for the table called, the one "Fluke Seedling, late," and the other "Milky White, earliest." Daw's Matchless, a large Fluke-shaped Potato; and Dundee Kidney, a red, many-eyed, oblong variety, were shown on Messrs. Carter's stand. Sutton's

Finest Regent told well for itself amongst many other well-known varieties, on Messrs. Sutton & Sons' fine stand of roots.—UPWARDS AND ONWARDS.

## THE WEATHER OF 1864 IN LANCASHIRE.

*January.*—This was a cold dry month. The mean temperature was 35°.03, or 2°.098 below the average of the last ten years, and 5°.62 below January 1863. The 7th was a remarkably cold day, the maximum temperature being only 19°, and the minimum 16°; excepting the 24th and 25th December, 1860, it is many years since we had so cold a day. The amount of rain was 1.21 inches, being 0.91 inches less than the average of the last ten years. It fell on seven days, which is 6.8 days less than the average. The barometer on the 4th at 10 a.m. stood at 30.55 inches, which was the highest point it reached on any day during the year. The prevailing winds were from the S.W.

*February* was also very cold. The mean temperature was only 34°.74, being 2°.478 below the average, and 6°.4 below February of last year. It was the coldest February we have had since 1860, on seventeen days it was below freezing-point. The amount of rain was 3.45 inches, or 1.639 inches more than the average of the last ten years; it fell on thirteen days. The prevailing winds were from the east.

*March.*—The temperature was still below the average of the last ten years 1°.449, the mean temperature being 39°.48. Rain fell every day from the 4th to the 14th, when the weather became fair, and we had some beautiful weather, with frost at night, so that by the end of the month gardening and farming operations were in a forward state. The amount of rain was 2.80 inches, being 0.065 inches below the average. The prevailing winds were from the east.

*April* was very dry and warm, the mean temperature being 47°.68, or 1°.536 above the average of the last ten years. The thermometer only once indicated as low a temperature as 32° on the night of the 13th. Rain fell on only eight days, the amount being 1.26 inches, and 0.815 inches less than the average. The prevailing winds were from the west.

*May.*—This was the most remarkable month on record for its extreme heat and cold. On some of the days from the 15th to the 21st the thermometer indicated 84° in the shade, and 127° in the sun, which was the greatest heat ever known here in May. The nearest approach to it was in 1858, when the thermometer indicated 82° in the shade, and 116° in the sun. This heat brought vegetation very rapidly forward, but the frosts at the end of the month disappointed all calculations of an early harvest, and did very serious damage to the Potatoes, Kidney Beans, &c. The mean temperature was 55°.87, being 2°.241 above the average. The amount of rain was 3.66 inches, or 1.456 inches above the average. It fell on twelve days, but only on one day from the 7th to the 27th. The prevailing winds were from the east.

*June* was wet and cold, and the frost on the 1st cut down the Potatoes, and even the young shoots of the Ash. Potatoes advanced in value fifty per cent. The greatest cold registered before in June since 1794 (taken at the Royal Society and Royal Observatory) occurred in 1797, 40°; 1802, 40°; 1841, 40°.3; 1848, 38°.7; and 1849, 38°.6. The mean temperature of the month was 58°.32, being 0°.302 above the average; the day temperature being 10°.37 higher than June 1863. It rained on twenty days, the amount being 3.98 inches, or 0.495 inches more than the average. The prevailing winds were from the west and south-west.

*July.*—This was a dry warm month. The mean temperature was 61°.95, being 1°.555 above the average. Rain fell on six days only, which was the least number of days in any month during the year. The amount was 1.59 inches, or 1.278 inches less than the average. The hay harvest was secured in prime condition, but very light on some grounds. The prevailing winds were from the south-west.

*August.*—This was again a very dry month, but the temperature was 1°.584 below the average of the last ten years, the mean temperature being 58°.47. Rain fell on twelve days, the amount being only 2.20 inches, or 1.98 inches below the average. The drought was very severely felt in some parts of England, many brooks and springs being quite dry, that had never been known to be dry before in

the memory of man. Water was sold for a penny a-gallon, and cattle driven some miles to water; mining and other operations were almost at a stand for the want of water; and in some parts of Lincolnshire the grass was almost burnt up, and they had to feed the cattle with the crops that were growing for their winter supply. The corn harvest was secured in fine condition, but Turnips were quite a failure in some parts. The prevailing winds were from the north-west.

*September.*—We had in Lancashire a copious supply of rain, which fell on twenty-two days, the amount being 3.39 inches, or 0.043 inches less than the average. The mean temperature was 55°.12, or 0°.484 above the average. The prevailing winds were from the south-west.

*October* was very dry. Rain fell on only nine days, the amount being 1.88 inches, or 1.429 inches less than the average of the last ten years. The mean temperature was 50°.32, or 0°.648 above the average. The prevailing winds were from the east.

*November.*—This was a very mild wet month. The Dahlias and other plants had received no check until the night of the 2nd, when they were all cut down by the frost. The temperature on three nights only was down to freezing-point. The mean temperature of the month was 41°.92, or 1°.86 above the average of the last ten years. Rain fell on fifteen days, the amount being 2.97 inches, or 0.639 inches above the average, it being the first month above the average since June. The barometer fell to 28.48 inches at 4 P.M. on the 14th, which was the lowest point it reached on any day in the year. The prevailing winds were from the east.

*December* was very dry. Rain fell on ten days, the amount being only 1.89 inches, or 0.603 inches below the average of the last ten years. The mean temperature was 38°.60, or 0°.275 below the average. The prevailing winds were from the S.E. and S.W.

The mean temperature of the year was 48°.125, or 0°.108 above the average of the last ten years. The total amount of rain was only 30.28 inches, or 2.894 inches below the average. It fell on a hundred and forty-eight days, or 32.3 days less than the average of the last ten years. The prevailing winds were from the east on seventy-seven days, and from the south-west on seventy-three days.—WILLIAM CARR, Clayton Bridge, near Manchester.

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

*LISSOCHILUS HORSFALLII* (Mr. Horsfall's *Lissochilus*).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Old Calabar, Western Africa. Flowers purple and pinkish white.—(*Bot. Mag.*, t. 5486.)

*DOMBEYA BURGESSLE* (Miss Burgess's *Dombeya*).—*Nat. ord.*, Byttneriaceæ. *Linn.*, Monadelphia Polyandria. Native of Natal, &c., in South Africa. A charming conservatory dwarf tree 8, to 10 feet high. Flowers in corymbs, white with crimson rays.—(*Ibid.*, t. 5487.)

*DENDROBIUM PARISHII* (Mr. Parish's *Dendrobium*).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Diandria. Native of Moulmein. Flowers rose colour.—(*Ibid.*, t. 5488.)

*PROUSTIA PYRIFOLIA* (Pear-leaved *Proustia*).—*Nat. ord.*, Compositæ (Mutisiaceæ). *Linn.*, Syngenesia labiatifloræ. Introduced from Chili by Messrs. Veitch & Son. A greenhouse climber rendered beautiful by the rosy-coloured feathered pappus on the fruit. Flowers in July.—(*Ibid.*, t. 5489.)

*SWAINSONIA OCCIDENTALIS* (Western *Swainsonia*).—*Nat. ord.*, Leguminifereæ. *Linn.*, Diadelphia Decandria. Introduced by Mr. W. Thompson, of Ipswich, from Western Australia. Flowers purple; "cannot fail to prove a great ornament to our greenhouses."—(*Ibid.*, t. 5490.)

*VALLOTA EXIMIA*.—Scarlet, with whitish throat. Mr. W. Bull, King's Road, Chelsea, had awarded for it a first-class certificate by the Floral Committee of the Royal Horticultural Society.—(*Floral Mag.* pl. 225.)

*CLEMATIS JACKMANNII*.—We noticed this last month.—(*Ibid.*, pl. 226.)

*CALCEOLARIA*.—*Bird of Paradise*. Flowers crimson edged with orange. Will be sent out next spring by Mr. Williams, Paradise Nursery, Holloway.—(*Ibid.*, pl. 227.)

**TREE CARNATIONS.**—*Delicatissima*, pink, barred with crimson. *Victoria*, light crimson, flaked with dark crimson. *Princess Alice*, bright yellow, flaked and barred with crimson. In the possession of Messrs. E. Henderson & Son, Wellington Road Nursery.—(*Ibid.*, pl. 228.)

**PELARGONIUM.**—*Indian Yellow*. "The acquisition of new colours amongst the varieties of so popular and useful a flower, cannot be otherwise than agreeable to those who follow up the parterre system of flower gardening. So much progress, indeed, has been made in this direction, that the term "Scarlet Pelargonium" is now made to stand sponsor for varieties furnishing a long catalogue of colours, running through the various shades of scarlet, crimson, rose, pink, salmon, and white. With this progress the name of Donald Beaton will ever be associated in the annals of flower gardening. For many of the later years of his life he devoted himself with much zeal to the cross-breeding of the Pelargonium, mainly with the view of raising new varieties adapted to supply the wants of the flower gardener; and we need do no more than refer to Stella, Cybister, and Lord Palmerston, to show that his labours were rewarded by a fair share of success. Up to the close of his life Mr. Beaton continued these cross-breeding experiments, and a large number of seedlings, bloomed and unbloomed, were left at the time of his death. From these, starting from the vantage ground already gained, a great further advance was expected, and has since been realised. Some few choice sorts had been selected by him for distribution shortly before he was taken from amongst us, and among them was the variety called Indian Yellow, of which we now give an illustration. The whole of the seedlings just referred to, bloomed and unbloomed, have passed into the hands of Mr. W. Paul, of Waltham Cross, and it is from the plant as bloomed by him during the past summer that our drawing has been made; while among the more juvenile batch of seedlings many choice novelties have appeared, of which the public will hear more in due time. Thus, from the ordinary race of scarlets, the bedder-out will have acquired amongst Pelargoniums, besides the pinks, roses, salmons, and whites he already possessed, a variety of tints which will be invaluable to him—passing off in one direction towards orange and yellow, and in the other towards purple-rose or magenta. These novelties, many of them, combine the prolific bloom of the Nosegay race with the better-shaped blossoms of the more ordinary kinds; and it is to this race of what may be called semi-Nosegays that our present subject belongs.

"Beaton's Indian Yellow Pelargonium is a variety of free growth and of dwarfish habit. It has, as will be seen, zonate leaves, and its flower-trusses are well furnished; the latter were, indeed, rather thin at the time of its first appearance in public, but, as the more natural season of bloom came round, this meagreness was altogether lost, and the plants bore well-furnished trusses as much as 4 inches across, and containing fifty or more of the large well-formed blossoms. The colour has a strongly marked shade of Indian yellow, which is at once apparent when the plant is brought into contiguity with either a pure scarlet or one of the magenta-tinted race. The colour may be described as an orange scarlet, with a suffusion of golden yellow, or a wash of the same colour overlaid. The variety, indeed, is a most unexpected and valuable addition to the materials for the parterre, all the more welcome as being the first of this colour which will be placed within reach of the flower gardener."—(*Floralist and Pomologist*, iv. 1.)

## TASMANIAN GARDENERS' AND AMATEURS' HORTICULTURAL EXHIBITION.

The spring show of flowers, fruits, and vegetables, under the auspices of the Gardeners' and Amateurs' Horticultural Society, took place in the Alliance Rooms, Hobart Town, on the 26th of October, 1864, and was in all respects successful above the average of these periodical displays. The collection of flowers was excellent both as regards the number, quality, and variety of the exhibitions, and the same remark may, with almost equal truthfulness, be applied to the other divisions of the Show. The fact that the season is what is generally described as a late one, rendered the floral collection and, in a minor degree, the vegetables,

less attractive than under more favourable atmospheric conditions precedent they would have been. In the floral department one of the first objects to attract the notice of a visitor, was a very beautiful *Torenia pulcherrima*, a new variety of stove plant, contributed by Messrs. Osborne and Sons. On the same table, and on either side of the handsome plant just named, were two large cases of cut flowers very artistically grouped, and the property of Messrs. Osborne and T. Johnson respectively. Both collections were very pleasing and of such nearly equal merit as to occasion some trouble to the Judges in arriving at a decision upon their merits, but the palm of victory was finally awarded to the Messrs. Osborne. On the first stand facing the doors stood a beautiful and valuable collection of twelve greenhouse plants, for which the Society's silver medal was most worthily bestowed. The next object to catch the eye was a magnificent *Strelitzia reginae* exhibited by the Messrs. Osborne, and which constituted one of the leading features of the Show. In the Amateur class, Mr. Johnson deservedly obtained a first prize for a handsome collection of six greenhouse plants, amongst which an *Azalea* was conspicuously charming. Amongst the cut flowers, all the collections of *Roses*, *Anemones*, and *Tulips* were disqualified from receiving prizes on the ground that they were not in accordance (as regards number of blooms exhibited) with the Society's schedules. Of the first-named class Mr. Johnson's were decidedly the best in the room, whilst another collection (for exhibition only) by Mr. Luckman, of Sandy Bay, possessed considerable merit. A box of *Anemones*, also transmitted for exhibition only, by Mr. Thos. Bentley, deserved commendatory mention. The *Tulips* of Mr. Johnson and of Mr. Smith (nurseryman) also merited favourable notice.

In the class for fruits a couple of very fine *Pine Apples* were shown by the Messrs. Osborne, some excellent *Pears* by Mr. Thomas, and some *Black Achan Pears* by Mrs. W. Lindsay. Amongst the *Apples*, the *Sturmer Pippins* of Mr. Smith, and the *Newtown Pippins* of Mr. J. Dickenson, were the most worthy of praise.

In the vegetable division, the Society's silver medal, for the best collection, was given to Mr. Chandler, gardener to His Excellency, and some remarkably fine *Cauliflowers* were sent in (for exhibition only) by Mr. Waterhouse, of Sandy Bay, and others by Mr. J. Wilson, of nearly equal merit. Some *Cabbages* exhibited by Mr. Culf, the Hon. Secretary, and one of which weighed no less than 14 lbs., were said to be the finest ever shown at an exhibition of the Society. A collection of *Onions*, contributed by Mr. J. Dickenson, and one of *Asparagus* by the Messrs. Osborne, were also of striking excellence.

We had nearly omitted to state that Mr. Abbott, as usual, contributed from the Royal Society's Gardens, an extensive and handsome assortment of growing flowers, which largely contributed to the pictorial effect, if we may so term it, of the entire display.

[The correspondent who sent us the above report, adds that there is no other colony of the Australian group so well adapted to the pursuit of horticulture as Tasmania. In fact it bears the enviable reputation of being "the Garden of Australia;" and no one after reading the report and the list we have of prizes awarded to *Pelargoniums*, *Calceolarias*, *Petunias*, *Cinerarias*, *Azaleas*, and numerous single specimens of other plants, fruits, and vegetables would be inclined to doubt its title to that reputation.]

### BEURRÉ CLAIRGEAU PEAR—MUSCAT DE SARBELLE GRAPE.

In Dr. Hogg's "Fruit Manual," first edition, he speaks thus of the *Beurré Clairgeau Pear*:—"A handsome and showy Pear, ripe in November. Its appearance is its greatest recommendation."

Two years ago I planted a bush of this sort, and I gathered from it in October this year half a dozen *Pears*, which I laid upon a shelf in my sitting-room, where a fire is kept up, and a few days ago I felt the *Pears*, and they showed no sign of ripening; but this day I tried them again, they had turned to an orange red colour, and are melting and musky, not coarse-grained, but very agreeable. I had thought of destroying the bush, or grafting it with some-

thing else, relying upon the rather unfavourable character given by Dr. Hogg; but as a *December Pear* I think it quite worth saving, and equal to most.

I do not think, too, that enough justice is done to the *Muscat de Sarbelle Grape* by Dr. Hogg. It does not certainly hang or set well, but the flavour is rich and sweet, and it is hardy and prolific. I am very sorry to differ from such a judge as Dr. Hogg, but I speak of fruit as of men—as I find them.—JAS. C. BARNHAM, *Norwich*.

[We are glad to find that *Beurré Clairgeau* succeeds so well at *Norwich*, and is not coarse-grained. It is doubtless a very handsome Pear, though, as our correspondent remarks, it is melting and musky, but very agreeable; still it will not compare in flavour with *Glou Morceau*, *Knights Monarch*, *Moccas*, *Winter Nelis*, *Henriette Bouvier*, *Thompson's*, and many others that are in season at the same time].

### ROYAL HORTICULTURAL SOCIETY.

THE second of the Saturday Shows was held at South Kensington on the 14th inst., in the same place as its predecessor—a heated room adjoining the eastern entrance and conservatory. The last Show, though small, was varied, and had a respectable appearance, but on this occasion there was very little to be seen, and hardly any one to see it. Between 3 and 4 o'clock in the afternoon, when we visited it, there were not half a dozen people in the room, and not more than a score or two in the conservatory listening to the band, which was indeed the only attraction. The objects invited were *Cyclamens*, and of these two small lots were shown. That from Messrs. E. G. Henderson, which received a first-class certificate, contained several pretty varieties, and well grown; the other, which was second, came from Mr. Aldred, Kilburn, and consisted of seedlings.

Messrs. E. G. Henderson also received second-class certificates for *Sonchus laciniatus*, with ornamental deeply cut bright green leaves; and *Senecio Ghiesbreghtii*, with large heads of yellow flowers, but rather coarse-looking.

From the Rev. George Cheere, Papworth Hall, Caxton, came a nice plant of *Mignonette*, and Mrs. Pollock Geranium, from a cutting put in in August, and kept in a cool greenhouse, the plant having its beautiful zonate markings very well developed. For both of these objects first-class certificates were awarded to Mr. Cheere.

Lastly, Mr. Meredith, Garston, exhibited splendid bunches of *Black Alicante Grape*, the large oval berries of which were covered with a dense bluish-black bloom. For this a first-class certificate was awarded. *Child of Hale*, a seedling between the *Muscat of Alexandria* and *Syrian*, and which has been already several times noticed in these columns, was also shown by the same exhibitor. The bunch was about 11 inches long, and 8½ across the shoulders.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

MANURING and trenching vacant ground should be proceeded with in favourable weather. The formation of new borders, and all descriptions of work requiring the removal of earth, should also be attended to. Clean plots of ground immediately the crops are off, as, if refuse is left, it only affords shelter to vermin. In mild weather the vegetable quarters would be much benefited by a dressing of salt and hot lime, repeated two or three times. This, by killing the present stock of slugs, will save much after-trouble. In dry weather stir between such crops as *Cabbage*, *Lettuce*, *Peas*, &c. *Artichokes* (*Jerusalem*), trench them out and store the best in sand for use, and replant the remainder. *Onions*, sow in a warm corner for spring use, and plant out small ones of last year's growth for the same purpose, and to bulb for kitchen use; the soil should be light and rich. *Shallots*, a healthy well-prepared situation should be chosen for them, some charred refuse applied, and the roots placed on the surface of the soil. By this treatment this useful bulb will increase most abundantly; no frost will injure it; and if worms are found troublesome at first, in displacing them, nothing more is required but a slight sprinkling of slaked lime; the roots soon push into the soil, and become firmly

fixed. *Horseradish*, this should be trenched out, the best roots stored in sand, the soil well manured, and the small replanted. In this department, as in others, alterations will occasionally be required, such as taking up and relaying Box-edgings that have become imperfect, or grown too strong and bulky, turning or surfacing walks with fresh gravel; and such jobs should be done, if possible, before the busy season.

## FRUIT GARDEN.

If any planting of fruit trees remains to be done, this should be seen to very soon, and every available dispatch used to complete it. If it is worth while to occupy ground with fruit trees, and incur the expense, &c., of planting them, it is certainly worth consideration whether the ground is in the best possible state of preparation for being planted with fruit trees, and to incur any expense and trouble which may be necessary to render the soil as suitable as it can be made for the kind of trees with which it is to be planted. To do this is seldom a work involving much direct outlay; for, if the ground is well drained, little else is required except labour, as a supply of good loamy soil can generally be obtained about most places in the country. It is useless to plant trees except there is a fair prospect of their doing well; and the necessary preparations for securing this can be more conveniently, cheaply, and effectually made before planting than afterwards.

## FLOWER GARDEN.

Let the most be made of favourable weather in the way of pushing forward new work, and all out-door operations. Turf, not level, is an eyesore all the season through, and it makes the mowing more tedious and difficult: hence it is worth an effort to spare time to make it level and smooth. Sweep lawns occasionally, to clear them of fallen bits of sticks, &c.; and use the roller here and on gravel frequently, to secure a firm smooth surface. If bulbs, &c., were planted, as advised, in the beds which are afterwards devoted to the usual bedding-out plants, they will now be pushing above ground, and will require a slight protection. Sawdust, leaf mould, or old tan may be put over such as the best sorts of Anemones, Scillas, Hyacinths, and Tulips, covering the surface afterwards, to resemble that of the other beds. Deciduous trees and shrubs for ornamental purposes, may be moved with safety while the mild weather lasts, and the roots protected by a mulching or covering of rotten dung; any in danger of being blown about by high winds, and their roots injured, to be supported by stout stakes. Where any shrubs, particularly choice sorts, are not growing vigorously, the extremities of the roots should be searched for carefully with a fork, and a trench, 18 inches or 2 feet wide, made around them on the outside, and fresh and enriched soil filled into the trench, in which the roots will extend and luxuriate during the summer. Although evergreens, for the most part, thrive well in loam of a middling texture, some, such as Kalmias, Rhododendrons, and other American shrubs, do best in a mossy humid soil, or peat earth; and, although deciduous shrubs in general thrive well in light loamy or sandy soils, some kinds, such as Roses and Acacias, flower better in a rich mellow loam; but whoever is curious in collections of shrubs is generally acquainted with the soils most suitable for their healthy growth.

## GREENHOUSE AND CONSERVATORY.

Stagnant air will prove unfavourable to the plants blooming in the conservatory, and water settling on the flowers will soon destroy them; moderate fires, with ventilation when the weather will permit, will be necessary. Water sparingly, and damp the house as moderately as possible. Do not allow bulbs to remain in the forcing-pit after they have developed their blossom, they may be preserved much longer in the conservatory. *Luculia gratissima* should have the favoured place. *Cinerarias* will now for some time add to the gaiety. In the greenhouse, *Pelargoniums* will soon require additional pot-room. See that your specimen plants are not too closely placed. It is extremely difficult to keep plants of this sort inactive, repress very active growth by keeping them cool and airy. *Calceolarias* may be slightly encouraged to grow. Where the twiners for covering the roof are grown in boxes, or have but limited root-room, as much of the surface soil should be removed annually as can be done without seriously injuring the roots, replacing it

with some good, rich, fresh soil, and this cannot be done at a better season than the present. Attend to the training of plants on wires and trellises. Fast-growing plants, such as *Tropæolums*, will require looking to frequently. The various composts that will soon be required for potting plants will be benefited by being frequently turned over during dry frosty weather. Such composts should not be allowed to become wet either from exposure to rain or snow.

## PITS AND FRAMES.

The stock of bedding-out plants should now be looked over; where anything is short remove a portion of the stock into a warm house to produce cuttings for propagation. It is often difficult to procure sufficient plants of some kinds in the autumn; and cuttings of all the more softwooded plants struck in this and the next month, and properly hardened off, will bloom equally well, if not better, than those struck in the previous autumn. It is, however, advisable to have bedding-out *Geraniums* and other woody plants struck and well established before winter.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

*Turf-pits, Earth-pits, &c.*—One of the greatest drawbacks attending turf-pits, in winter, is the harbour that the dry turf walls afford to mice and rats, especially the former. The evil is increased if any old stakes or boards have been used to help to keep up the back wall: hence it is often better to dispense with the boards, so as to afford no lodging-place behind them. Even with them all will go on well enough until a sharp frost come; but then, if you are forced to have the whole covered up for a week or so, the mice will be apt to poach on your preserves, nibbling out the centres of Cauliflowers, and even pretty well taking away all but the outside leaves of blanched Endive and Lettuce; the more blanched the more will they like it. During the last frost we thus lost a lot of nice Cauliflower. Cats are a good remedy at times, but they do little good when shut up in total darkness. The old tales of cats seeing best in the dark must be taken with a certain allowance; for, though they do see well in twilight and comparative darkness, when shut up without any light they will have little but their scent and their whiskers to guide them. Traps, and phosphoric paste spread on bread and butter, are best for the common mice; but large grass mice are difficult to catch, and are generally most readily captured by fine wire snares in their runs.

*Peas and Beans.*—Protected those sown under protection. Will make the first sowing out of doors as soon as the ground is suitable. We think that by transplanting the first crop we gain a little in time, and we save hunting after slugs and mice in winter.

*Celery.*—Removed the stubble, so as to expose the heads of the Celery. We have not yet had frost severe enough to necessitate a covering of branches, and then some litter above it. In very severe weather, when much protection is necessary, the branches, roughly hooped, keep the weight of the litter from pressing on the foliage of the Celery, especially when a sudden thaw comes. When the leaves are much injured, and the leaf-stalks broken, the Celery is apt to decay in the bed, and in that case it will keep better if taken up rather dry, and packed closely together in a dark place. The snow falling heavily will be a good protection if frost come. We can prognosticate little at present in these sudden changes.

*Potatoes.*—Looked over those intended for seed, laying them open that they might not sprout too much. A nice lot in small pots, the latter filled with roots, in the Mushroom-house, are waiting for a chance to be transferred to beds, with just a little heat from leaves below them. These generally crop all the sooner from the roots being confined. At first much heat is disliked by the Potato, and early ones rarely crop well when it is given. Slow and sure is a better motto. To have nice young ones now, they should have been started in October. Winter-grown ones, however, are seldom nice and mealy unless they get sun; and young waxy ones, or what seem so, may be had with less trouble by planting about the middle and end of July, and keeping the produce in dryish earth.

**Dwarf Kidney Beans.**—Sowed in boxes in front of Cucumber-bed, to be afterwards transplanted into beds or pots. At this season we prefer pots, as they are easier managed and can be moved, where room is limited, to suit any fresh arrangement. How few can complain of an inability to fill all their glass space, the cry is all in an opposite direction. How shall we give anything like justice to the myriads of things requiring our attention, and all demanding the best positions?

**Cabbages.**—Stirred the surface of the soil and put some charred rubbish round the plants, which will keep some enemies from them and Lettuces; but we have also been obliged to place a net all round the quarter to save the nice young plants from rabbits and hares. This garden is surrounded by an Ivy fence which looks nice in the place, but it is a fine harbour for these marauders, and they lie so close in it that there is great difficulty in dislodging them. These thieves do eat the Cabbages, and, therefore, do a little good for themselves; but when they nip out the points of young trees; and top the shoots and leave them, they do so much mischief that no quarter should be given them. For want of netting-in a young plantation of trees, &c., we used to find a stout softish string well dipped in oil and tar, and stretched all round some 6 inches from the ground, a good preservative, taking care to run a brush with the moist material along the string when it became dry. We shall be obliged to try this and other plans again. Will any correspondent say what is the best and simplest protection from these marauders in the case of young plantations? Our experience leads us to the conclusion, that what will deter at one time ceases eventually to be any bugbear, animals in this respect becoming too much like men, who are apt to form ideas of what is vicious and wrong, in proportion as they refrain or indulge.

Cucumbers and other matters much the same as previous weeks.

#### FRUIT GARDEN.

Pruned, &c., in favourable weather. Watered Strawberries under cover and coming into bloom. Looked over Grapes, and examined the fruit-room. Apples are in general keeping well, as they ought to do after such a dry summer. Continued most of the operations alluded to last week.

#### ORNAMENTAL DEPARTMENT.

The snow will temporarily stop our work of grubbing up old stumps and roots from a part where trees have been felled, and where some more ornamental objects will be substituted. The best way to do such work, when the ground is full of roots, is not only to take up all the stumps, but to trench the ground and clear it of roots. Where the ground had previously been thickly planted, this is a very laborious operation, and takes up much time; but it is by far the best, as the decaying roots of the removed trees are apt to become harbours for various sorts of fungi, &c., that will be apt to hurt the roots of the fresh trees. The next best, perhaps, and which we will adopt to save time, is to take out the stumps that are most in our way, to chip the outside of hardwooded trees of the bark and a portion of the alburnum, coat these parts with tar, and then bore two or three holes about the centre of the stump. The tar will prevent the dock stooling at the sides, and the holes, becoming receptacles for moisture, will cause the dock gradually to rot away. Then take out holes from 5 to 10 feet in diameter, and fill up with good fresh soil, and plant on knolls if deemed advisable, which is suitable for most of the Pine tribe. Such fresh soil would be a necessary addition to the exhausted earth at any rate. The old soil, outside of the mounds, will derive fertility from the want of cropping; but when the roots of the young trees penetrate into the old soil, and if it be deemed necessary, more fresh soil may then be added. This hole, mound, and platform planting enables a person to do the work sooner at first, and yet gives the fresh trees a good chance, and then more help can be given at a convenient opportunity, when time can be better spared. In most gardens large jobs can hardly be carried out and thoroughly finished at once, with the usual complement of labour, when it could be comfortably managed when done at different and suitable times. The plants also get the fresh food just as they are prepared to enjoy it. Nevertheless, we would prefer thorough trenching

at first, as then the trees might be helped continuously all the same, whether planted on the level or elevated on mounds. In the latter case, if the turf is removed, the mound can be easily widened. Would Mr. Barnes kindly tell our readers if he has yet added to the mounds of the *Wellingtonia* group at Bicton, the size of these mounds, and the size of the plants now? It would be interesting to many to know.

**Turning-up Flower-beds and Borders.**—Where these are not planted this work has been proceeded with in suitable weather. One of our points is deep stirring, and generally mixing just a little of the subsoil, stirring that, however, and leaving it mostly where it is. Last season, though so dry, Scarlet *Gernaniums* did splendidly, never better; but in taking some up we traced the roots fully 4 feet down. All their roots were much deeper than usual. Surface-rooting plants, as *Calceolarias*, suffered most. Never did there seem such rooting work before. The ground turned up now seems in many cases as full of roots, as an old wig is full of hair. The turning-up of these, and the frost and the atmosphere together, will reduce these decomposing roots into manure for the future crop. We prefer ridging-up all such soil, and mixing considerably as we go along, and keeping a good portion of the surface soil at the surface, instead of turning it down to the bottom of the trench. The surface soil is the richest, and we wish the richest to be at the surface to encourage quick growth when the plants are turned out. The comparatively poorer soil at a greater depth gives just enough of a check to promote free blooming. Were the richest soil turned to the bottom, we would have more foliage than we wanted, and would be obliged to plant thinner and to disleaf considerably besides. To insure richness at the surface, what little we can give in the shape of leaf mould or well-rotted hotbed manure (mostly leaves with a little dung), we place on the surface. This, though no doubt the practice would be condemned by good agriculturists, we generally throw over the ridges and leave it there for a considerable time exposed. We no doubt lose manurial properties by the exposure, but we gain in sweetness and the killing of worms, &c., by the frost. We generally turn it in a few inches without levelling the ridges before it would be too much dried by spring winds. In such mellow surfaces most things succeed well when they are turned out, and one secret of a rich flower garden in summer, we believe to be free growth at first and more stunted growth afterwards. The deep stirring prevents much of a check, secures so far against dryness, whilst the comparative poverty of the deeper soil prevents over-luxuriance. Of course when great luxuriance, as in the case of fine-foliaged plants, is the object, the opposite course should be followed, as with *Ricinus*, *Canna*, &c.

Went on as occasion permitted in looking after young plants, damping, giving air, putting a little fire on, especially during the day, and potting greenhouse and stove plants as detailed in previous weeks.

**Ice and Snow.**—Had we not some ice we would have been snow-rolling. It is just rather thin for that purpose, but still a good deal could have been obtained; and if a little more fall we will most likely take advantage of it. We presumed almost everybody knew how to do the work, but everybody does not; as not so long ago we saw some big men lifting the snow gingerly on shovels, after scraping it and throwing it into a cart—a very roundabout mode of proceeding. The snow will roll only when it is soft or fresh-fallen. Just stoop down, and make a good-sized ball as if you were to go snowballing on a large scale. Turn the ball over and over in the snow, and as it collects and gets large you may want a man or two to help you with the huge mound that adds to itself in bulk and solidity as it is rolled along. The size of the huge ball may be in proportion as to how you are to get it into the ice-house or ice-stack. In the former case it may be as large as may be turned on to a barrow, the barrow being laid down on one side. If to be taken by a cart, the larger the mound is the better, as then it can be cut into great lumps with a shovel. A heap is easiest made for a stack when you can roll the snow from all the surrounding ground. If to be carted it is of less moment where you bring it from. If the snow is fresh and soft a little water will help to solidify it when knocked firmly together. In the case of a stack out of doors, watering the

outside before a frosty night will be a good preservative before covering.

It is now very many years since we listened, delighted and instructed, to some of Mr. Keane's literary and scientific essays at the West London Gardeners' Association for Mutual Improvement. We wish he would write just such an essay on the principles of ice-preserving as he would have done then, with just the view before him of such a number of upturned faces, with ears taking in every word, and reasoning and criticising going on quietly until he had uttered the last word. The temperature of the ice is to us far from a settled question. The boiling water used for each foot of ice, see page 29, must raise its temperature. Suppose that ice must absorb some 140° to become fluid, is it not feasible to suppose that the boiling water would help to promote that fluidity? There is a little doubt about the whole question, so much so that we have for years done little or nothing in an artificial way to the ice. There might be a difficulty, too, in getting the boiling water, and it would be easy to err as to the proper quantity. Would our friend give us more insight into this matter?—R. F.

**COTTON.**—In these days of cotton famine, as there are many persons who have hothouses who would like to rear plants for the sake of curiosity, I may state that I have some samples of Sea Island and New Orleans Cotton seed by me, and sometimes I have quite a number of sorts, which I test for the Cotton Supply Association of Manchester. I shall be happy to send a few to any one on receipt of a stamped and directed envelope.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

**TRADE CATALOGUE RECEIVED.**

- W. Cutbush and Son, Highgate, London.—*Catalogue of Select Vegetable, Flower, and Farm Seeds.*
- C. E. Brydges, St. James's Square, Cheltenham.—*Spring Catalogue of Kitchen Garden, Farm, and Flower Seeds.*
- R. H. Poynter, County Seed Establishment, Taunton.—*Retail List of English and Foreign Seeds.*

**COVENT GARDEN MARKET.—JANUARY 14.**

The supply, both of out and in-door produce, is, for the season, well kept up. Grapes are unusually plentiful; Pines just sufficient to meet the demand; good dessert Pears very scarce; Oranges and Lemons good and abundant. Forced vegetables consist of the same articles as last week, and the Lettuce from the continent is tender and good. Unless very severe weather occur, there seems little likelihood of there being much change in quotations for some weeks.

**TO CORRESPONDENTS.**

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

**CUCUMBERS FOR EXHIBITION (W. Brown)**—There are no varieties superior to those you mention.

**GARDEN POTS (A Constant Subscriber)**—For the smaller sizes the price is about 2s. a-cast; very large pots are dearer.

**FLOWERS REQUIRED.**—Can any of your readers tell me where to procure some healthy plants of the double blush, double flesh, and double copper-coloured varieties of *Primula acutis*, or the double white *Hepatica*?—REV. H. H. C., *Rectory, Drayton Banchoy, Tring.* [Any one able to supply our correspondent should direct to him. We cannot insert answers.]

**WULFENIA (J. G.)**—"What is the plant mentioned in the following extract from Gilbert and Churchill's 'The Dolomite Mountains'?"—"Churchill gave an account of his hunting among the mountains for *Wulfenia*, a rare and graceful plant, something like a Foxglove, about 18 inches high, provided with a rosette of large scalloped leaves, of a Lettuce-like form, and a stem all but bare of leaves, crowned with a spike of deep purple-blue flowers. It grows here in vast masses, on the mountain side, 6000 feet above the level of the sea, and when sunlight falls upon it its glowing tint is visible at a great distance." It is *Wulfenia carinthiaca*. There is a drawing of it in Jacquin's "Icones Plantarum Rariorum." Willdenow says it is found in rich soil on the highest of the Carinthian Alps. Flowers in July. Root creeping and perennial. Leaves in a tuft, all radical, obovate, 4 inches long, smooth, shining, and crenate. Flowers large, handsome, in a dense cluster, on a slightly scaly stem.

**GLAZING WITHOUT PUTTY—REMOVING OLD PUTTY—VENTILATING AN ORCHARD-HOUSE (Live and Learn)**—We have no experience in glazing without putty. Perhaps some of our correspondents will favour us with the most approved method of doing this, and also whether it will stand wind and wet. Old putty may be softened by applying to it rags dipped in a saturated solution of caustic potash, leaving them on for twelve hours, or by rubbing a hot iron along the putty. In ventilating a wall covered with glass we prefer having the ventilators horizontally along the back throughout the entire length, and this especially when there are Vines or Peaches on the back wall. In addition to this it is as well to have ventilating openings in front, immediately below the roof. We like these better than vertical openings the full length of the rafter at 6 feet or any other distance apart, they being very well for moveable houses, but not desirable for fixed structures.

**WEEDS ON GRAVEL WALK (A. B.)**—If you spread salt on the walk in dry weather, so as to cover it about one-eighth of an inch thick, that will destroy most of the grass. This, repeated from time to time, as the weeds present themselves, is, we fear, your only effectual remedy, as you do not like the walk to be frequently broken up. Taking off 3 inches of the gravel, and placing a layer of gas lime an inch thick, relaying the gravel over it, and rolling firm, would most certainly prevent weeds growing for some time, but the smell, we think, would be unendurable.

**CLIMBERS FOR VERANDAH (An Old Subscriber)**—We do not know of a hardy variegated climber except *Lonicera brachypoda aureo-reticulata*, a variety of the Sweet Jasmine (*Jasminum officinale foliis aureis*), not yet sent out; and a variety of Vine (*Vitis vinifera variegata*). Of evergreen climbers there are few suitable for the purpose. The following would answer:—*Ceanothus azureus* and its variety *pallidus*, *C. dentatus*, *rigidus*, and *floribundus*; *Berberis Darwini*, *Cotoneaster Simmonsi* and *buxifolia*, *Arbutus procera* and *Menziesii*, *Escallonia glandulosa* and *macrantha*, *Garrya macrophylla* and *elliptica*, *Eugenia Ugni*, *Photinia serrulata*, *Ligustrum japonicum*, *Magnolia grandiflora*, the Exmouth variety, and *floribunda*; and *Crataegus pyracantha leucocarpus*, and *crenulatus*. Unless yours is a warm locality the following, in addition to the two varieties of *Pyracantha*, though not evergreen climbers, are, nevertheless, fine flowering climbers, and would answer much better:—*Jasminum nudiflorum*, *Solanum jasminoides*, *Passiflora cœrulea*, *Glycine sinensis* and its variety *alba*, *Forsythia suspensa*, *Jasminum chrysanthum officinale grandiflorum*; *Caprifolium Sheperdii*, *odoratissimum*, *sempervirens*, *Brownii*, *Youngii*, and *floribundum*; *Bignonia radicans*, *Clematis lanuginosa*, *florida* var. *Sieboldi*, *azurea* and its variety *odorata*; *Shillingii*, and *venosa*; *Aristolochia siphon*, and *Eccremocarpus scaber*. *Manetti* stocks are the stocks on which Roses are often budded, being rooted suckers or cuttings of the *Manetti* Rose, a strong free-growing and rooting variety.

**CHEILANTHES FRAGRANS OR ODORA (Felix-mas)**—This is very difficult to cultivate. It is from the south of Europe, and requires an airy yet moist greenhouse temperature. *Cheilanthes* generally like a moist but not stagnant atmosphere, and are very impatient of moisture on the fronds; syringing should, therefore, be avoided. We found it did best in a well-drained pot, in a compost of pieces of sandstone, the size of a Walnut, one half and the other half turfy peat and loam in equal quantities, with a free admixture of silver sand. It was kept well watered at the root, and in a light but partially shaded greenhouse fernery, having a moist but airy atmosphere, and it grew fairly. A hot, close, or stagnant atmosphere, and very wet and dark situation, are most injurious to it.

**PEARS FOR PYRAMIDS (Tyro)**—*Doyenné d'Été*, *Baronne de Mello*, and *Urbaniste*, succeed in that form. The other two we never knew to be so trained.

**BOTANICAL CLASSIFICATION** (*G. Brown*).—We do not remember your query.

**LEAF MOULD, &c.** (*A Subscriber*).—You may keep your leaf mould and loam in bags in your cellar without injury to anything but the bags. Tarpaulin is better than mats for covering pits, as it excludes wet, especially if you put a little hay or straw between the glass and tarpaulin.

**DIRECTION** (*M. A.*).—Mr. Thomson, Archerfield, Drem, N.B. We are not aware that the Vine you mention has been supplied to the trade.

**FUCHSIA SEEDLING** (*Sarniana*).—It is impossible to give an opinion of the merits of a seedling from a single flower and leaf. It seems a cross with corymbiflora. The other little scrap seems to be a *Crucianella*, but no judgment can be formed on such fragments.

**SOUTH AUSTRALIAN PLANT** (*Country Curate*).—We do not know it by the colonial name "Shirt's Desert Pea," but as its "flowers are scarlet, with a large black eye," we think it is, probably, *Clinanthus puniceus*. Portraits of this are in the "Botanical Register," "Horticultural Society's Transactions," and Faxton's "Magazine of Botany."

**CRICKETS IN CUCUMBER-HOUSE—POPLAR CUTTINGS** (*A Weekly Reader*).—The most effectual remedy is to poison them by spreading phosphorus paste on thin slices of bread, the same as if buttering these thickly. This preparation placed in their haunts will kill many—certainly all that partake of it. It should be laid at night, as the directions on the cover will inform you. Now is a good time to insert Poplar cuttings, but the sooner it is done after the leaves fall the better. They should be taken from the strong growths of last year and be cut into lengths of from 8 to 12 inches, two-thirds of their length being inserted in the soil. The distance should be about 6 inches apart, and 12 or 15 in the rows. The moderately strong wood is the best.

**INDIARUBBER PLANT SHEDDING ITS LEAVES—PLANTS FOR HANGING BASKETS—THRIPS ON FERNS** (*A Constant Reader*).—The leaves fall, we should think, through want of light, and the extreme dryness of the atmosphere in the drawing-room; for though this plant will endure almost any treatment, it cannot thrive in a dark and extremely dry atmosphere for a lengthened period. The plants for baskets outside a west window are few, and, though we name some, we do not vouch for their doing either well or flowering at the time named—*Vincas*, six sorts; *Lysimachia nummularia*; *Antirrhinum linariifolium*; *Campanula garganica*, *C. Barrelieri*, *Convolvulus mauritanicus*, *Linaria cymbalaria*, and its variety *alba*; *Saxifraga japonica*, and *S. sarmentosa*, *Sedum Sieboldi*; and the variegated-leaved *Strawberry* is very pretty; but nothing is hand-omer than the variegated gold and silver, and the small green-leaved *Ivies*. If the Ferns in the fern-case are not much infested with thrips the latter may be removed with a damp sponge, to which they will adhere on its being drawn over them, care being taken not to injure the fronds. If very much infested the best plan would be to fill the case quite full of tobacco smoke, removing the case to an out-house for the operation. If fumigated the fronds of the Ferns should be dry. By removing the thrips with a damp sponge you may soon clear the case, but to prevent their attacks in future the atmosphere should be kept more moist.

**BOOKS** (*A Goose*).—"The Garden Manual" for twenty postage stamps, and "The Poultry-Book for the Many" for seven postage stamps, can be had free by post from our office, and will suit you.

**NAMES OF FRUIT** (*F. H.*).—1, *Henriette*; 2, *Glou Morceau*; 4 and 6, *Napoléon*; 5, *Easter Beurré*.

**NAMES OF PLANTS** (*E. H. N.*).—1 and 5, *Athyrium Filix-fœmina*; 2, *Asplenium microdon*.—A rare British variety of either *A. lanceolatum* or the *Adiantum nigrum*; yours is not advanced enough to say to which it belongs. 3 and 7, *Lastrea dilatata*; 4 may be *Asplenium lanceolatum* in a wretchedly starved state, but is more like a bad frond of *A. fontanum*; 6, *Polystichum aculeatum lobatum*, young; 8, *Lastrea æmula*; 9, *Asplenium Adiantum nigrum*. (*Allen Mallet*).—*Pteris aquilina*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.

(Continued from page 40.)

#### ARTIFICIAL HATCHING.

THERE is nothing absolutely new under the sun! Even hatching chickens by artificial means has been carried on in Egypt, China, and other eastern countries, from the remotest ages to the present day; and yet in England it has hitherto proved a failure in a commercial point of view. It is true that in Egypt, where they hatch many millions of poultry annually, artificial hatching is a trade of itself, carried on by hundreds of proprietors of ovens, and their success in hatching will be apparent when it is stated that they sell one hundred newly-hatched chickens for about 3s., or that they will return, free of charge, sixty chickens for every hundred eggs entrusted to them for hatching. It is also true, that the climate and soil of Egypt are more favourable than those of England to the rearing of poultry; but then, why should we not appeal to science to assist us in overcoming the drawbacks of our soil and climate? No doubt we shall never be able to produce poultry so cheap as in Egypt, where soil, climate, labour, and cost of land are eminently favourable to a cheap production; but in compensation we can obtain far higher and in proportion more remunerative prices for our poultry, their feathers, and manure.

It is an acknowledged fact, that the artificial hatching of eggs in England although carried out on principles not in strict harmony with the natural incubation of a hen, has yet proved far more successful than the artificial rearing of chickens. This, of course, is solely to be ascribed to the improvident way in which chickens are treated before they have their natural protection, their feathers, in a climate where the sudden changes in the temperature of the atmosphere, and the almost continual humidity of the soil, act prejudicially on young animal life; but surely these are difficulties which can easily be overcome? Do we not obtain in England by artificial means such splendid tropical fruits as no tropical climate can produce? And why not surpass Egypt in rearing poultry, if not in cost at least in quality and scientific feeding and fattening, for which far more remunerative prices are obtained? Well, all this can now be accomplished in England by any person who will follow my plan of hatching, rearing, and fattening poultry by artificial means. This plan must necessarily be modified according to the importance of the breeding establishment and the number of eggs to be hatched daily—from one to a thousand—but the main principles essential to the successful artificial breeding of poultry will, under any circumstances, remain the same.

THE ARTIFICIAL HATCHING ROOM.

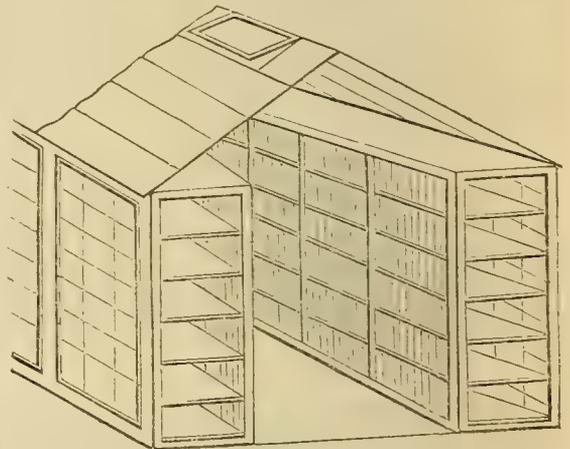

Fig. 17.—Artificial Hatching Room.

The floor of this room should be formed of concrete, the sides of moveable glazed frames, and the roof of boards covered with asphalted felt, slates, or zinc. The interior ought to be fitted along the sides with moveable shelves, which can be drawn out for cleaning. These shelves will be divided into separate compartments, 3 feet long, 2 feet wide, and 1 foot high, the sides and the front, which forms a door, should be made of galvanised iron wire. In each compartment ought to be a frame lined underneath with long fleece the same as in the portable artificial mother's. In these compartments the chickens are placed from their birth up to a week or ten days old, when they are put under the care of an artificial moveable mother (see fig. 15), in small establishments, or in the artificial rearing home in large establishments. These compartments ought to be covered with a felt carpet, which must, however, be kept well cleaned and occasionally dipped in boiling water. The best way to supply food and water to such young chickens is by means of two

Fig. 18.—Feeding and Drinking Saucers for Young Chickens.

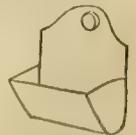

Fig. 19.—Feeding and Drinking Vessel for Young Chickens.

saucers (see fig. 18), one within the other, and between which the food or water is put. This will prevent them wetting themselves or scratching the food about. The hatching room will require no heating apparatus, as the

heat from the hatching apparatus, which is kept in the middle of this room, will keep the temperature sufficiently high during winter. Near the ridge of the roof ventilating-frames should be fixed, and near the floor one or two sliding doors should be provided to allow of the admission of cold air.

Chickens hatched in a dry atmosphere will never be so strong and healthy as those hatched in a moist heat, as is evident from the difference in the appearance of a brood hatched in a loft, and one hatched in the field; and as a moist temperature is highly desirable, it should be provided for in artificial hatching. The apparatus described below, although only calculated to hatch one egg per day, combines the same advantages as one capable of hatching one thousand eggs per day, and will answer for all the requirements of an amateur breeder. Besides it is so portable and convenient in its construction that it can be placed in a bed-room, and while hatching it will keep the room warm day and night, and the light from the gas or lamp will serve as a night light.

PORTABLE ARTIFICIAL HEN FOR HATCHING.

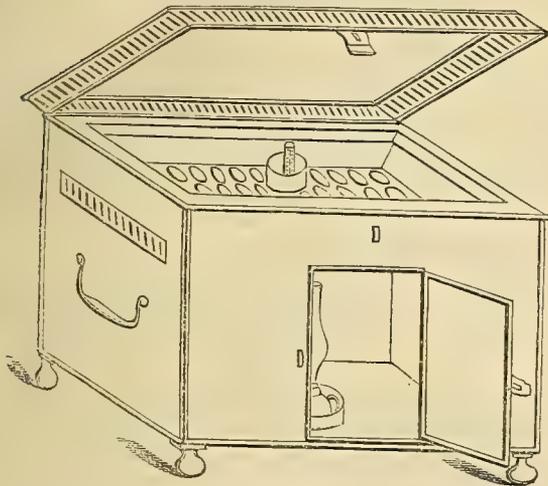

Fig. 20.—Portable Artificial Hen for Hatching. Perspective elevation.

From the above perspective elevation and section it will be seen that the hatching apparatus consists of separate parts. 1. A glass-covered box. 2. A water tank. 3. A floating vessel. 4. A gas or oil lamp.

The glass-covered box is made of japanned tin, it has a glass door through which the light can be seen. The bottom of this box is perforated in the centre for the admission of air to the lamp, and the other part is carpeted to receive the chickens as they leave their shells. About 12 inches from the bottom are four brackets to receive the water tank. The lid has a perforated border for the escape of the vitiated air and the steam from the water. The sides are provided with handles for carrying the box from one place to another, and it stands on four knobs to allow of a free passage of air underneath.

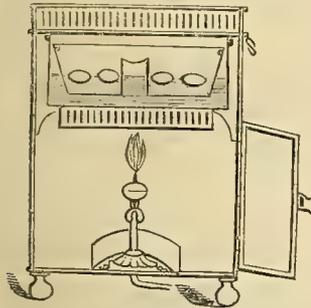

Fig. 21.—Transverse Section.

The water tank is made of tin, and a little smaller than the box so as to allow about half an inch for the free passage of air all round.

The floating vessel is also made of tin, and is a trifle smaller than the water tank, so as to allow of its floating in it. The centre of this vessel has an oval opening in which a registering thermometer is kept to show at all times the temperature of the water. The bottom of this vessel is covered with about an inch deep of silver sand on which the eggs are placed. By means of the central opening and that between the vessel and the tank, the air is kept in a con-

stantly moist condition. The lamp may burn either gas or oil, but gas is certainly preferable.

MANAGEMENT OF THE APPARATUS.

This is so simple that it can be entrusted to a child, and only a very few directions will be necessary.

1st. Fill the tank with hot water till the floating vessel reaches the top level, then see that the water has a temperature of nearly 112°. Then light the lamp. Should the heat increase reduce the flame, but if the temperature rises or decreases but slowly it can be regulated by admitting more or less air through the door of the box.

2nd. The principal point, however, is, that the temperature on the sand should not vary much from 105°, and it will be found that with a water-heat of 112°, the sand will be at 105°, and the eggs at 98°. For beginners it is always best to put the apparatus in action for a day or two before putting eggs in it.

3rd. Turn the eggs once or twice a-day, and keep the water replenished as it evaporates.—G. K. GEYELIN, *Civil Engineer, London.*

(To be continued.)

PROFITS OF POULTRY-KEEPING.

In the article "Poultry-keeping from a Commercial Point of View," your correspondent, Mr. G. K. Geyelin, makes a calculation of the extra revenue to be derived from 3000 hens, and arrives at a result of rather a startling nature. It is true, Mr. Geyelin allows nothing for deaths, &c.; but does he not make a serious mistake in calculating the value of the eggs at 15s. per 100? I am buying good fresh-laid eggs now at 1s. per dozen, or 8s. 4d. per 100, and, of course, the man from whom I buy them gets a good profit, as he has to buy them from the farmers' wives.

I fear that 5s. per 100 would be nearer the mark than 15s. and if so, that would reduce the revenue from £675 to £225. Still, even then there would be a good profit left, and it is astonishing that the cottagers of England do not attend more to egg-producing than they have done.—C. S. J.

[We consider you are quite right, and we have warned our readers against accepting Mr. Geyelin's profit and loss statements. Those published and others which we have from him for publication, are all far too much in favour of the poultry-keeper.—Eds.]

KENDAL AND NORTH-WESTERN COUNTIES POULTRY SHOW.

THE tenth annual Show was held on Thursday, Friday, and Saturday last, in the Commercial Assembly Room, Highgate, Kendal.

On account of the Committee not being able to secure the commodious room that has been at their disposal for the past two years, and there not being another room sufficiently large in the town, they were obliged to strike out a number of classes which otherwise would have appeared on their list.

The chief feature in the Show was the *Game* classes, and the principal attraction amongst the Game was the class for local exhibitors, thirty-three pens competing for the honour of being the best pen in the county. The silver cup and second prize were won by Mr. Thos. Robinson, of Ulverston, and the third and extra first prizes by Mr. Woof, of Old Hutton; an extra prize, in the same class, was taken by Mr. Thompson, of Old Hutton. As a class, this was, perhaps, the best in the Show, not a single bad bird of any sort being seen in any pen. In the Single Game cock and cockerel class the competition was very close. For the cup it was a severe struggle between the best two pens, and it was only after a long comparison that the Judge decided in favour of Mr. Fletcher's splendid bird, though, in our opinion, the cock shown by Mr. M. Graham, of Kendal, was equally deserving.

There was a capital show of *Bantams*, and in the class for Game cock and two hens, no less than thirty-nine pens competed.

In the *Hamburgh* classes the different varieties were well represented; the magnificent birds of Sir St. George Gore being conspicuous in each class, though the head prize, a

silver cup, the gift of the Member for Kendal, was carried off by Miss Emily Beldon with a pen of Silver-spangled, the only pen she had in the Show.

In the *Dorking* class the Hopton Hall birds were more fortunate, the silver cup being awarded to them; though there was very little between them and the second prize birds shown by Mr. Knowles.

The *Cochin-China* classes were well represented, considering there was not much inducement, there being no cup given in this class. In the coloured birds Mr. Zurhorst took first in adults, and Mr. Stretch in chickens. In Whites, the Rev. Frank Taylor took first in adults, and second in chickens; and the Rev. E. Lucas was the winner of the first prize in chickens. The whole of this class were exceedingly good; the White *Cochins* especially, being far above the average. The Black *Spanish* mustered very badly, and those that were shown deserve no special remark.

Amongst the *Ducks* there were some excellent pens, some of the north-country birds treading close upon the prize pens of our most celebrated breeders. In the "Any Variety Class," were some remarkable birds, one pen disqualified for only having one Duck instead of two, contained the largest drake we ever remember seeing. The prizes, however, were given to the small fancy sorts.

On the whole the Show was a very successful one, it was exceedingly well managed, and was most respectably attended, the principal families in the neighbourhood taking great interest and bestowing their patronage in a very liberal way. On the last day the room was thronged the whole time, and in the evening was crowded to excess. All the Committee want to make this Show the first in the north is a suitable room, and we hope that next year they will be successful in securing the room that has in previous years been at their disposal.

The following is the list of awards:—

**GAME (Whites and Piles).**—First, T. West, St. Helens. Second, F. C. Ellison, Kendal. Third, Sir St. G. Gore, Bart., Hopton Hall, Derbyshire. Highly Commended, H. Thompson, Mintonhorpe.

**GAME (Black-breast and other Reds).**—First and Cup, T. Statter, Bury, Lancashire. Second, J. Fletcher, Stoneclough, near Manchester. Third, W. Boyes, Beverley. Highly Commended, T. West, St. Helens; J. Fletcher, Stoneclough. Commended, J. Gelderd, Kendal; M. Billing, jun., Birmingham.

**GAME (Any other variety).**—First, T. West, St. Helens. Second, H. Worrall, West Derby, Liverpool. Third, M. Billing, jun., Birmingham. Highly Commended, L. Casson, Ulverston. Commended, W. J. Cope, Barnley.

**GAME HENS (Any age or variety).**—First, T. Robinson, Kendal. Second, J. S. Butler, Poulton-le-Fylde. Third, W. Boyes, Beverley. Highly Commended, T. West, St. Helens, Lancashire.

**HAMBURGS (Golden-pencilled).**—First, Sir St. G. Gore, Bart., Hopton Hall, Derbyshire. Second, F. Pittis, jun., Newport, Isle of Wight. Third, A. Nuttall, Manchester. Highly Commended, J. Pearson, Wibsey, near Bradford; T. Wrigley, jun., Middleton; W. H. Dyon, Bradford; S. Smith, Halifax; R. Roy, Worcester.

**HAMBURGS (Golden-spangled).**—First, N. Marlor, Denton, near Manchester. Second, Sir St. G. Gore. Third, C. Broadbent, Saddleworth. Highly Commended, D. Tait, Grasmere; Miss Irving, Penrith; J. Robinson, Garstang; W. Cooper, Helmsley, Yorkshire; M. Billing, jun., Erdington, Birmingham. Commended, T. Brooks, Keighley.

**HAMBURGS (Silver-pencilled).**—First, Sir St. G. Gore, Bart. Second, J. Robinson, Vale House, Garstang. Third, D. Elleray, Bowness.

**HAMBURGS (Silver-spangled).**—First and Cup, Miss E. Beldon, Gilstead, Bingley. Second, J. Robinson. Third, Sir St. G. Gore, Bart. Highly Commended, J. Altham, Accrington. Commended, G. E. Hardman, Rawten-stall (chickens); J. Fielding, Newchurch, near Manchester.

**DORKINGS (Any variety).**—First and Cup, Sir St. G. Gore. Second, H. Knowles, Liverpool. Third, D. Parsons, Cuerdon, near Preston. Highly Commended, J. K. Fowler, Prebendal Farm, Aylesbury; J. Robinson, Vale House, Garstang; J. Gunson, Whitehaven. Commended, W. W. Rutledge, Kendal; T. Roger, Lancashire. *Chickens.*—First, J. K. Fowler. Second, A. Woods, Sefton, near Liverpool. Third, J. Robinson. Highly Commended, H. D. Holt, Windermere; W. W. Rutledge, Kendal. Commended, F. R. Pease, Southend, Darlington.

**COCHIN-CHINA (Cinnamon and Buff, or Brown and Partridge-feathered).**—First, F. W. Zurhorst, Donnybrook, Dublin. Second and Third, Miss E. A. Aglionby, Grasmere (Buff). *Chickens.*—First, T. Stretch, Ormskirk. Second, W. Newsome, Bingley. Third, Miss E. A. Aglionby. Commended, J. Withnshaw, jun., Nantwich.

**COCHIN-CHINA (White).**—First, Rev. F. Taylor, Kirkby, Lonsdale. Second, F. W. Zurhorst, Donnybrook, Dublin. Highly Commended, W. Dawson, Hopton, Mirfield, Yorkshire. *Chickens.*—First, Rev. E. H. Lucas, the Rectory, Edith Weston, Stamford. Second, Rev. F. Taylor, Kirkby, Lonsdale. Third, J. Hodgson, Whittington, Burton. Highly Commended, G. Lamb; J. Hodgson; Rev. F. Taylor. Commended, Rev. F. Taylor.

**SPANISH (Black).**—Prize, W. Harvey, Sheffield. *Chickens.*—First, W. Newsome, Bingley. Second, S. Robson. Third, A. Heath, Calne, Wiltshire. Highly Commended, A. Heath.

**ANY NEW OR DISTINCT VARIETY NOT PREVIOUSLY MENTIONED.**—First, C. W. Brierley, Middleton, Manchester (Polande). Second, T. Brooks, Keighley (White-crested Black Polande). Third, R. W. Boyle, Rosemount, Dundrum, Co. Dublin (Brahma). Highly Commended, H. Lacy, Hedden Bridge (Dark-pencilled Brahma Footra); J. Brauwell, Moorhead, Accrington (Brahma Footra); S. Butterfield, Keighley (Black Hamburghs).

#### SINGLE COCKS.

**GAME.**—First and Cup, J. Fletcher, Stoneclough, near Manchester. Second, M. Graham, Kendal. Third, C. W. Brierley, Middleton, Manchester. Fourth, W. J. Cope, Barnsley. Highly Commended, J. Hodgson, Whittington, Burton; T. West, St. Helens; M. Billing, jun., Erdington, near Birmingham. *Cockerels.*—First, M. Billing, jun. Second, T. Statter, Bury, Lancashire. Third, T. West. Fourth, G. Robinson, Kendal. Highly Commended, F. King, Wellington, Salop. Commended, H. Thompson, Milnthorpe.

**DORKING.**—First, W. W. Rutledge, Kendal. Second, R. D. Holt, Windermere. Highly Commended, F. R. Pease, Southend, Darlington; J. Robinson, Vale House, Garstang.

**SPANISH.**—First, F. Crook, Forest Hill (Chicken). Second, J. Cragg, Kendal.

**BANTAM (Game).**—First, J. Munn, Newchurch, Manchester. Second, R. Dodge, Sheffield. Third, G. Smith, Staveley. Highly Commended, J. Munn; R. Dodge; J. Crossland, jun., Wakefield.

**BANTAMS (Gauc).**—Cup, First, and Fourth, J. Munn, Newchurch, Manchester. Second, G. Smith, Staveley. Third, G. Maples, jun., Wavertree, near Liverpool. Highly Commended, Miss E. A. Aglionby, the Hollins, Grasmere (Piles); W. B. Mapplebeck, jun., Woodfield, Mosely, Birmingham; J. W. Morris, Rochdale; Sir St. G. Gore, Bart.; Hon. T. Fitzwilliam, Rotherham. Commended, M. Leno, jun., Birmingham; E. G. Hornby, Westmorland; D. Parsons, Preston.

**BANTAMS (Any other variety).**—First, W. B. Mapplebeck, jun., Birmingham. Second, M. Leno, jun., Bedfordshire. Third, W. Harvey, Sheffield (Booted White Bantams). Highly Commended, M. Leno, jun.; F. R. Pease, Southend, Darlington; W. J. Cope, Barnsley.

**Ducks (White Aylesbury).**—First and Third, J. K. Fowler, Aylesbury. Second, Mrs. M. Atkinson, Kendal. Highly Commended, F. M. Hindle, Haslingden; J. Robinson, Garstang.

**Ducks (Rouen).**—First and Cup, A. Woods, Sefton, Liverpool. Second, T. Nelson, Milnthorpe. Third, R. W. Boyle, Rosemount, Dundrum. Highly Commended, T. Hall, Haslingden; T. Robinson, Ulverston; Sir St. G. Gore, Bart., Hopton Hall, Derbyshire. Commended, T. Statter, Bury, Lancashire; J. Redhead, Kendal.

**Ducks (Any other variety).**—First, C. W. Brierley, Middleton, Manchester. Second, D. Parsons, Cuerdon, Preston. Third, J. F. Fowler, Aylesbury (East India). Highly Commended, T. Hall, Haslingden (Wild); R. Dickenson, Bowness; F. W. Earle (Black East Indian); C. W. Wilson, Kendal (Muscovy); I. Atkinson, Burton.

**SPECIAL CLASS.**—Extra First and Third, R. Woof, Old Hutton, Milnthorpe. Cup and Second, T. Robinson, Ulverston. Extra Second, H. Thompson, Milnthorpe. Highly Commended, M. Graham, Kendal; J. Gelderd, Colin Croft, Kendal; J. Hodgson, Whittington, Burton. Commended, J. Hodgson; E. G. Hornby, Westmorland; H. Thompson.

#### PIGEONS.

**CARRIERS.**—First and Second, H. Yardley, Birmingham. Commended, J. R. Robinson, Sunderland; J. W. Wooler, Darlington.

**TUMBLERS (Almond).**—First, F. Key, Beverley. Second, T. Kew, Burton. **TUMBLERS.**—First, W. Towerson, Egremont, Cumberland. Second, T. Kew, Burton, Westmorland. Highly Commended, H. Yardley, Market Hall, Birmingham.

**OWLS.**—First and Commended, W. Towerson, Egremont. Second, H. Yardley.

**POWTERS AND CROPPERS.**—Prize, T. Kew, Westmorland.

**BARBS.**—First, W. B. Van Haansbergen, Newcastle-on-Tyne. Second, R. Thompson, Kendal. Commended, H. Yardley, Birmingham.

**FANTAILS.**—First, W. B. Van Haansbergen, Newcastle-on-Tyne. Second, H. Yardley, Birmingham.

**TURBITS.**—First, R. Thompson. Second, H. Yardley. Commended, J. R. Robinson, Sunderland.

**TRUMPETERS.**—First, J. R. Robinson, Sunderland. Second, W. B. Van Haansbergen, Newcastle-on-Tyne. Commended, F. Key, Beverley, Yorkshire.

**JACOBS.**—First, E. E. M. Royas, Greenhill, Rochdale. Second, J. Thompson, Bingley.

**ANY OTHER VARIETY.**—First, W. B. Van Haansbergen, Newcastle-on-Tyne. Second, H. Yardley, Birmingham. Commended, E. E. Royas; F. Key (Nuns).

**JUDGES.**—*Poultry:* Mr. R. Teebay, Fulwood, Preston. *Pigeons:* Mr. Sergencson, Liverpool.

#### PERTH POULTRY SHOW.

THIS was held in the City Hall, Perth, on the 12th and 13th inst.

**SPANISH.**—First, Viscountess Holmesdale, Linton Park. Second, P. Bruce, Perth. Third, Brown & Cochrane, Perth. Highly Commended, Cochrane & Ross, Perth; Mrs. M. U. B. Cross, Monifieth; D. Stewart, Perth; J. Morrison, jun., Perth.

**DORKING (Any colour).**—First, Viscountess Holmesdale. Second, W. Cooper, Inchture. Third, J. Elsworth, Campsie Junction. Highly Commended, W. Cooper; J. Elsworth; J. Spalding, Leslie; Viscountess Holmesdale; Brown & Cochrane.

**COCHINS (Any colour).**—First, Brown & Cochrane. Second and Third, Viscountess Holmesdale. Highly Commended, Brown & Cochrane. Commended, W. Cooper; T. Y. Craig, Gallatown.

**BRAHMS (Any Colour).**—First, Lord Kinnaird. Second, Mrs. H. Barclay. Third, W. Cooper. Highly Commended, Mrs. Cross. Commended, W. Cooper; Mrs. H. Barclay.

**GAME (Any colour).**—First, Mrs. Cross. Second, J. Anderson, Meigle. Third, J. Morrison, jun. Highly Commended, Mrs. Cross. Commended, W. Bonthron, jun., Kirkcaldy; R. Carmichael.

**HAMBURGH (Pencilled).**—First, Mrs. Cross. Second, Mrs. Brown, Abercainry. Third, Mrs. White, Perth. Highly Commended, C. Lockhart, Kirkcaldy; D. Penman; R. Coupar, Pathhead.

**HAMBURGH (Spangled).**—First, Viscountess Holmesdale. Second, A. Copland, Kintore. Third, Mrs. Cross. Highly Commended, Mrs. Brown. Commended, W. Kiddle, Cowdenbeath; W. France.

**BANTAMS (Any colour).**—First, G. Spalding, Drumsturdie. Second, Mrs. Cross. Third and Highly Commended, J. Anderson. Commended, F. L. Roy, Nenthorn.

**ANY OTHER BREED.**—First, Countess de Flahault (La Flèche). Second and Third, W. Cooper (La Flèche and Crève Cœur). Highly Commended, Countess de Flahault (Buff Poland); T. Ross (Scotch Grey).

**GEESE (Any colour).**—First and Second, W. Cooper. Third, J. Laing.

**DUCKS (Aylesbury).**—First, J. Anderson. Second, Lord Kinnaird.

**DUCKS (Rouen).**—First, Second, and Commended, Mrs. Cochran, Lundie Mills.

**SWEEPSTAKES.**—*Spanish Cocks.*—First, Viscountess Holmesdale. Second, Brown & Cochran. *Dorking Cocks.*—First, Viscountess Holmesdale. Second, J. Elsworth. *Game Cocks.*—First, Mrs. Cross. Second, J. Anderson.

### BRAHMA POOTRAS.

THINKING that Burmah might not be the country intended by Mr. Tanner, as mentioned in our last Journal, we wrote for information, and this is Mr. Leworthy's reply:—

"Last night I went the distance of two miles to have an interview with Mr. Tanner, whose family are residing in India now, with the exception of himself and youngest daughter, who left when she was four years of age.

"Mr. Tanner resides at Pilton, near Barnstaple, and he said—I have been a resident for twenty-one years at Chumar, situated near the River Ganges, about three hundred miles from Calcutta, in India. I left there fifteen years since. Two years before I left I purchased at a bazaar at Chumar, some Brahmin Murge (fowls) at 2s. each, a very high price, but they were large fowls. At the same time common fowls in the market were worth 6d. each." He said, also, that they did not derive their name from the river Brahma Pootra, but 'Brahmin,' means in India the highest caste of the people, and those birds being beyond the common order of fowls, the Indians called them Brahmin Murges. (In English, High Caste fowls.)

"Mr. Tanner was of a decided opinion that the Brahma fowls that I had, and which attracted his attention in my poultry-yard, were a pure breed of Brahmin fowls, and of precisely the same breed as those he kept in India.

"Mr. Falconer, resident at Newport, Barnstaple, told me about one year since, that about thirty miles below Chittagong, by the river Brahma Pootra, there is a very high bank adjoining the river. On this bank are numerous cottages built, the women residing in which employ themselves by taking clothes for washing for the gentry in that neighbourhood, and those cottagers keep only this kind of fowls; and at Chittagong he could not get any refreshment except fowls or eggs. He compared eggs to the stones of a pavement, being so plentiful. He had read a description of the Brahma Pootra fowls, and it agreed with those which he had seen in the Brahma village.—H. LEWORTHY, Newport, Barnstaple."

### POULTRY SHOW IN PARIS.

FIVE of the salons in the Palais de l'Industrie, the sides of which were covered a few months since with the productions of the artists of all nations, presented an extraordinary appearance on the 19th, 20th, and 21st inst. In place of history, battles, landscapes, and portraits were collected the inanimate bodies of fowls, Turkeys, Geese, and Ducks. The Exhibition was a great success: there were more than five hundred contributors, and between two and three hundred specimens of poultry of one kind and another. Nineteen departments were represented.

The arrangements were admirable; sloping tables were placed around, and double stands of the same kind in the centre of each room. These were covered with blue paper, upon which the poultry was laid out with ample space on all sides, the various lots each consisting of four specimens, being separated by fillets of wood painted red, so that every article exhibited could be seen perfectly. On the walls were neatly-painted devices, containing the names of the classes and localities of production, and hung about with laurel intermingled and enlivened by a few coloured ribbons. The first day was devoted to arrangement; the second, till one o'clock, to the decisions of the jury, after which the public was admitted at a charge of half a franc; and the third to exhibition and sale of the articles.

The jury was composed of Count Leopold le Hon, President, representative in the Corps Legislatif of the department of Ain, famous for its poultry; two inspectors-general of agriculture, four farmers, and four dealers in poultry. The sum of four thousand francs was devoted to prizes, besides medals in gold, silver, and bronze. The grand prize consisted of a large gold medal and a thousand francs. The awards were marked by means of oval cast iron tablets, painted blue, with the raised letters picked out in gold colour. The fowls were divided into five categories—birds of the races of La Bresse, of La Flèche, of Houdan, of Normanby, and miscellaneous. The first of these was by far the most numerous, as the poultry is the most esteemed. One gold, one silver, and a number of bronze medals and honourable mentions were awarded in each class, and the grand prix d'honneur was awarded to M. Gorgondet, of Trefort, in the department of the Ais, for four pullets of the race of La Bresse. The other five classes consisted of Turkeys, Ducks, Geese, Pigeons, Guinea fowls, and other poultry. The department of Seine-et-Oise carried off the first and second prizes for Turkeys, that of Orne the gold medal for Geese, and Rouen the same for Ducks. The fowls of La Bresse were not so remarkable for size as for smallness of bone and plumpness; and the manner in which they are prepared for market is quite artistic. Some of the Geese were truly gigantic; but the Turkeys would not have borne comparison, perhaps, with those of Leadenhall Market. The sale was very brisk, and the names of almost every celebrated gastronomic establishment in Paris were to be seen on tickets in all directions. Forty and fifty francs were asked and easily obtained for prize Geese and Turkeys; and fowls that had obtained medals were marked in the morning after the Exhibition as high, if not higher, than thirty-six francs each. Poultry is an article of great importance in France, and the rearing of fowls in La Bresse, Burgundy, is one of the staple occupations of the locality; but it is not carried on in large establishments, experience proving that the collection of large numbers of poultry in one place invariably gives rise to epidemics amongst them. The Bresse race is not, however, so pure as some others, the delicacy of the meat and rapidity of the fattening being supposed to depend principally on soil and the mode of feeding. The Bresse pullets can be fattened at the age of three months, while those of other localities cannot be got ready for market till after the fifth or sixth month. The modes of rearing poultry differ in different localities. At La Bresse a pullet of three months is worth about two francs, and the fattening occupies them from fifteen to thirty days. To produce what is called a fat pullet takes about five gallons of meal, made from maize and black wheat. This is mixed with curdled milk, and given to the poultry in balls; the greater part are, however, only half fattened. A fine fat pullet sells for six to ten francs; an ordinary one for three to five francs, at the local market of Bourg. The poultry of the Flèche race is fed in the department of the Sarthe, on barley and black wheat meal mixed in the same way with milk. Four young cocks, for which a prize was given, averaged 11 lbs., (English) each, and were valued at 20s. to 24s. each.—(*Journal of Society of Arts.*)

### SEX OF EGGS.

As the sitting season has again arrived, one becomes reminded how desirable it would be to be able to have cockerels or pullets from this or that hen, and also of the utter uncertainty which seems to hide the future sex of the egg.

The idea has been mentioned that the position of the air-vessel affords an indication; and also that the shape of the egg, whether round or oblong, is an indication, but these notions have been proved deceptive. I heard that eggs that were wrinkled at the small end would produce cockerels, and eggs that were smooth would produce pullets. Wanting some pullets two years ago, I set the smoothest-ended eggs I could get, reared ten chickens from the brood, and they turned out to be nine cockerels and a pullet, or just the reverse of what I had been led to expect.

Recently, light from another quarter has been thrown on this subject; and it is now stated that, of a batch of eggs of

one laying, those first laid will produce a majority of pullets, and those last laid a majority of cockerels. It would certainly be very desirable to be able to regulate this matter to some extent, and I hope this new idea will be carefully tried by enough of your readers to ascertain if there is any truth in it.—F. H.

### THE COLOUR OF THE BILL OF THE AYLESBURY DUCK.

PERMIT me to ask, Why is it that the cream-coloured bill of the Aylesbury Duck is held to be an indispensable qualification at all our poultry shows? Judging by my own experience, I must confess my entire disbelief in that being the natural colour, because, if natural, the mere change of locality could not affect it. Now, it so happens, I have repeatedly claimed at various shows a prize pen of Mrs. Seamons, containing Ducks with bills of the orthodox colour, of course, and although I have tried all manner of means to preserve their delicate pristine shade, yet with all my care, I have invariably failed. Two or three months sufficed to change the former sickly paleness into the healthy orange bloom to such an extent, as totally to unfit them for competing against Mrs. Seamons or Mr. Fowler. I have not the least doubt if my birds had been returned to Aylesbury, a brief sojourn there would have effectually blanched the bill to its prize-taking shade. This being not only my experience, but that of a great many other lovers of these beautiful birds, is it not natural for us to suppose that there is something in the character of the soil in which Ducks are constantly boring for food, to account for this? The soil of the Aylesbury vale, I understand, is a compound of clay, sand, and chalk—a mixture quite sufficient in my opinion, to produce by constant working in it, as Ducks do, the peculiar colour of the Aylesbury's bill. If in this respect my supposition is correct, it must be pronounced an injustice to exhibitors living in less favoured localities, for poultry committees, more especially the Birmingham Committee, to persist in maintaining the cream-coloured bill as a "*sine qua non*."

There is another consideration in connection with this question to which as food-producers and food-consumers it behoves us all to give our serious attention. I allude to that of weight. While the Rouens, with their unfettered and world-wide competition, are gradually but surely making their way upwards—bidding fair ere long to outstrip the celebrated exploit of Mrs. Seamons' 27 lbs. pair of Aylesburys at Birmingham, the Aylesburys appear to have reached the goal of their ambition, and are resting complacently on the laurels they have won, contented if only one pen should save the honour of the class at Birmingham, while all the rest, from the second-prize downwards, were left in the unenviable position of vanquished rivals. Now, by renouncing the cream-coloured bill as the *only* standard, the consequence would be to bring into action an amount of feeding-experience unknown before, and instead of 27 lbs. being the isolated maximum weight at Birmingham, it would be the minimum. The fine large frame of this species warrants me in making such an assertion, now that we see what has been accomplished in the Rouens. We cannot therefore but deprecate a rule which, instead of stimulating the competition of the community at large, unwittingly serves to confine that competition to a small section of it.

It also will not be out of place here to draw the attention of the Birmingham Committee as well as exhibitors to the following significant facts, which will show to the former that the proposed alteration will tend somewhat to the increase of their funds, and to the latter what they have to expect under a continuance of the present system.

Referring to the catalogues, I find the entries for Aylesburys average about nineteen only per year during the last four years, whereas the Rouens nearly treble them—the last year giving fifty-one entries, making a difference of nearly £12 in entry fees in favour of the latter, and why this surprising difference? Simply because the Rouens have no stringent, unattainable, stipulation attached, while the Aylesburys have, and as a consequence the latter class ceases to attract any entries, but from those interested, and those uninitiated in the mystery. And when exhibitors are informed that, with two exceptions, all the prizes awarded

in this class at Birmingham for the last four years have gone to Aylesbury, and learn also the reason, and that it is utterly useless attempting to compete with Aylesbury under existing conditions, I shall not be surprised to see this class gradually dwindle into insignificance.

Let me, therefore, in conclusion, suggest that as the colour of the Mallard's and Grey Call's bill has been adopted for imitation in the Rouens, the colour of the White Call's bill should not be entirely ignored in the Aylesbury, the orange being indisputably the natural colour. Not that I would wish to make even this an arbitrary standard; but to make it "a fair field and no favour," I would propose that the prizes should be awarded to the heaviest pen of birds, "with bills of any shade" between orange and cream colour, provided the colour of the bills of each bird in the pen uniformly matched, and were besides in every other point the nearest to faultless.

These few observations are dictated by no unkindly feeling, but purely from an honest desire to advance the common weal.—G. B. H.

### RABBITS.

I HAVE tried several kinds—viz., Himalayas, Silver Greys, Lop-ears, and lastly a beautiful pair of Patagonians, which have just arrived from France—and out of the whole of this stock not one has died from the time they have been separated from the doe; but of course I have illness amongst my stock occasionally, but with a change of food they always recover.

Can any of your readers inform me the cause of a Himalayan doe sometimes having amongst the litter one young one which is born perfectly black, but at the age of about two months changes to the colour of a perfect Rabbit of its kind? I have one now which is just changing, and I see that all about the head turns white first. Both the does and young ones are fed on cabbage leaves, carrots, celery, &c., twice a-day, besides as much oats and bran as they wish, and whenever a doe appears thirsty she is allowed as much water as she will drink while it is held to her; and they are kept in very dry and warm hutches.—J. S. W. BLACKETT.

### LIGURIANISING AN APIARY.

WILL Mr. Woodbury have the kindness to give me his opinion of the following project for multiplying my Ligurians in the most rapid manner possible? I want to combine two objects. First, to insure as far as I can the continued purity of the stock which I received last autumn from his apiary; and secondly, to displace as expeditiously as may be my old black bees by the new comers. I propose to obtain, next season, as many new stocks of Ligurians as there are bars furnished with brood-comb in the Italian hive. At the proper period—i.e., as soon as I perceive drones issuing from the hive—I purpose to furnish as many empty hives as I wish to have artificial swarms, each with its bar and appendage. The hives are then to be immediately placed on the site of the hives of black bees, just previously removed, choosing a fine warm day in mid-May for the purpose, and shifting the hives at an hour when the greater number of bees are engaged in foraging—say from eleven to twelve in the forenoon. I assume that drones will make their appearance in the Ligurian stock several days before they are seen in the common ones. By this means all the black bees then out of the hives will return to their former domiciles, but without drones. But I imagine that if I leave matters here, there will scarcely be a sufficient number of black bees in the all-but-empty hive to meet the emergencies of their new and altered condition. I want the hive to be forthwith replenished with comb, &c., that the new Ligurian queen may at once proceed to the business of her vocation. My next step will be to take a few more black bees from the removed hive. This I shall essay to accomplish thus:—I shall take each hive of black bees into a dark room, or rather a room lighted by only a pane of glass; by gently moving the hive, not rapping it as in driving, I shall, no doubt, get a considerable number of the workers, then in the interior, to fly to the light, where I can examine them, and

in case the queen should not have joined them, liberate them, when they will unquestionably wend their way to the hive prepared for their reception. Having done this I shall remove each hive of black bees, subjected to this rough and depopulating process, a mile or a mile and a half from my apiary. This will, I hope, if thoroughly carried out in my apiary, according to my present intentions, remove, or at all events very much diminish, the probability of the young Ligurian queens becoming impregnated with any but Ligurian drones. I am fully aware that in this way I shall increase the chance of having, in some few instances, perhaps, only drone eggs laid in some of the hives; but even taking this into account, are there any other means so simple and at the same time so efficacious for accomplishing my purpose of getting immediately an apiary replenished with the pure Ligurian stock? I once tried an analogous experiment in a partially-lighted room, although not for the purpose of raising artificial swarms, and it answered admirably. It will, of course, be understood that my project embraces the entire removal, to as great a distance as possible of all my stocks of black bees.—W. L.

[It requires, in my opinion, two seasons to ligurianise an apiary. The first should be devoted to furnishing all your stock with Italian queens, paying but little heed to their impregnation, since no matter how that takes place, all will breed pure Ligurian drones next year,\* when all that do not breed true Italian workers should be weeded out and replaced by young queens, which, amid the multitude of Ligurian drones which will then exist, will have every chance of true impregnation. Thus much by way of preface. I will now consider the details of the plan submitted to me.

When you take out a brood-comb to make an artificial swarm in the way you propose, you should select one which contains brood in every stage from the egg to the sealed nymph, and should also take all the bees that are on it at the time, otherwise the attempt may fail from the lack of young bees which constitute the class of nurse-bees described by Huber. If the vacancy in the Italian stock can be at once supplied by a comb of black worker brood, the abstraction of bees will scarcely be missed, and may be repeated almost *ad infinitum* about every other day; but every comb of black brood should be marked with the day of the month on which it is inserted, and not employed for breeding Ligurian queens until say twelve days afterwards. If combs of black worker brood are unattainable, the place of those extracted should be occupied by empty worker-comb, which will be rapidly filled with eggs; but if no worker-comb be attainable, the remaining combs must be brought together, and the vacancy left on one side. In order to avoid the possibility of risk to the Italian queen, do not be content with not being able to find her on the comb about to be removed, but make sure of her not being there by ascertaining her presence on another comb at the time.

Putting the new artificial swarm in the place of a strong stock in the way you describe will, together with the adhering bees, generally insure a sufficient population without the aid of after-manipulation, but it should be furnished with enough combs to obviate the necessity of comb-building for the first fortnight, since all combs built before a queen is hatched are pretty sure to be drone-combs.

Artificial swarms will frequently raise a great many royal cells. On the ninth or tenth day, all but two of these may be extracted and employed in the formation of other swarms, which will thereby gain a considerable advantage in point of time. They should be cut out with a triangular bit of comb attached (apex downwards) and inserted in a similarly-shaped hole cut in a brood-comb taken from either a common or a Ligurian colony; the latter of course being preferable as a *dernier resort* in the event of the failure of the inserted royal cells. In all these operations the greatest care is necessary to avoid bruising or chilling the royal embryos and for this reason they should be conducted as rapidly as possible in the middle of a warm day.

If in the spring you can manage to transfer two or three of your stocks of common bees into frame hives, it will be a great assistance, and will, I think, go far to render the task of ligurianising your apiary as easy as it is interesting.

\* *Vide* my papers on parthenogenesis in Nos. 25 and 30 of THE JOURNAL OF HORTICULTURE, for the explanation of this curious fact.

Instructions for performing this operation were given in No. 75 of "our Journal."

Any further information will be most readily afforded by  
—A DEVONSHIRE BEE-KEEPER.]

## A NEW CHAPTER IN THE NATURAL HISTORY OF THE BEE.

BEE COMMOTIONS AND QUEEN ENCASUREMENTS.

(Continued from page 42.)

LANGSTROTH has admitted that during one season he lost a great many young queens artificially reared; though he attributed the circumstance to his having sited his hives so closely together that the queens, on returning from their aerial excursions, unable to discriminate their own domiciles, went astray and perished. I quite admit that it is a matter of some importance to have hives sited a little apart from each other, and to have those which are uniform in shape somewhat distinguishable in colour or appearance; but the proximity and similarity of hives are not, as Langstroth states, the entire cause of such losses. An experimental apiary must always be conducted upon the principle of a full knowledge of circumstances and probable results. I never think of calculating upon invariable success in all cases of artificially-reared princesses, and certainly never feel much disappointed when some of them fail by reason of any of the contingencies to which I have hinted they are liable. In cases where queens are reared naturally, not from compulsion but from choice, I very seldom indeed find them go wrong.

Now, it may be asked, How is this? The answer is easy. When a queen is reared with the view of swarming, it is a crowning point in a long series of preparatory doings all tending to such a climax. Drones are reared just to suit the necessities of the case, and when the swarm leaves all the elements and conditions of success are left behind which Nature requires. Seldom indeed in such circumstances have I found a failure. Not so, however, in cases of an artificial character. Here the rearing of a queen is a new idea, so to speak, towards which the bees are not, it may be, entirely prepared. Some elements or conditions of success may be wanting. Even though a queen is reared, there may be such a scarcity of drones not only in the apiary, but more especially in the hive, which by necessitating the queen to continued flights for weeks, as I have seen her, may in the end lead to accident and death. Nay, my experience would lead me to go a step further on this subject when I say, and it is not a haphazard statement, that a want of drones in the young queen's own hive, though abundant elsewhere, is a condition too often detrimental in its results. This, in my opinion, renders impregnation sometimes tardy, if not uncertain, and is the cause of her frequently going astray altogether.

Just look through the glass of the unicomb on such occasions, and see the preparations for the youthful queen's departure. See her led, if I may so express myself, by an escort of her subjects to the very entrance of the hive, where she is literally beckoned away by the clearest signs. See, too, the drones, fully alive to the exigencies of the moment, precede and follow her. Ah! it is not in such circumstances as these that I fear a successful result; it is only when these natural elements are absent in the hive that I often dread the consequences. What will be thought of the fact that this very season out of fifteen young princesses I reared from the eggs of one queen, and placed at the head of so many hives, six disappeared in consequence of being exposed, as I believe, to the unfavourable conditions to which I have here referred?

But to return. After such experiences as above detailed, I set myself anew to the task of reconsidering the whole question in all its varied characteristics and aspects. I found that no uniform principle could be applied so as to account for all the commotions and encasements occurring in the apiary, originating as they evidently did from a dissimilarity of causes. The foreign element of stranger bees could not account for all of them, neither could it be said that age and debility as affecting the queen applied to many of them. The question then occurred to me, Is it necessary to

assume *a priori* that these curious phenomena do originate from one and the same cause? I could not from collating the mass of materials regarding these in my possession come to such a conclusion, and therefore I have attempted to evolve such a theory upon the subject that while it in some measure satisfies my own mind, I yet submit with the greatest diffidence in the pages of this Journal, inasmuch as I find from extracts from the writings of Herr Rothe, Herr Wallbrecht, the celebrated Dzierzon, and other German authorities, that the subject is not unknown in that land of philosophical research of myths, mysteries, and metaphysics, but is viewed as one of the greatest enigmas in apianian science. This I must reserve, however, for a subsequent communication.—J. LOWE.

(To be continued.)

### REGICIDE AMONG BEES.

I HAVE just read with pleasure the contributions of our two scientific friends, the Devonshire and the Renfrewshire Bee-keepers. I can indeed indorse the statement of the former in reference to the regicide he refers to. I had one good stock which swarmed on the 7th of May, and on the 24th sent forth a large second swarm, just seventeen days after the first. After this last was hived and settled, I observed the old stock, and on the ground, near it, I found a cluster of bees shamefully treating a beautiful large queen. I was surprised with what tameness she took their insults. I liberated her, and fearing it might be the queen of the stock which had just issued, I put her on the alighting-board, and she walked in. Next morning I found her dead on the ground.

Some time after liberating the queen referred to, I again noticed the old stock, and was exceedingly annoyed at finding another queen barbarously treated by the bees. I had hardly patience with them; but, thinking she was a supernumerary, I released her also, and put her on the alighting-board of another stock which I knew to be queenless. She was so weak and feeble, and lame in the hind legs, from the bad treatment she had met with, that she could hardly walk in, and never did any good. I carefully observed the stock from which these queens had been so shamefully expelled. The bees never seemed contented—never worked—would run up and down the hive in a stream, apparently in agitation, as if searching for something. Some time afterwards I examined this stock, and was annoyed at finding neither eggs, larvæ, nor queen in it. I then cut a nice piece of comb, full of brood in all stages, from another hive, and inserted it in this. In two days I observed a marked difference in the conduct of the bees, and found four or five royal cells in progress, three of which were ultimately sealed and opened in the usual way; but weeks afterwards, on again examining the hive, I found it queenless. I believed these rebels had destroyed these princesses, as they had attempted to do the former ones. I tried them with another bit of comb, but they refused to raise any more queens. In the autumn they fraternised with another stock, and began removing their stores, and continued to do so until the cold weather put an end to their mischief.

Will our kind friend, the "RENFREWSHIRE BEE-KEEPER," tell us the best way of securing the object mentioned in his addendum? It is, in my opinion, the great desideratum of bee-keeping. A full account from his pen would oblige us all.—EDWARD FAIRBROTHER.

### RANCIDITY IN BUTTER.

I SEND a pound of butter, in the hope of receiving some information as to the cause, or a remedy for, the acrid, pungent taste which you will find to exist in it.

The butter is fresh, the dairy and utensils scrupulously clean and well-cared for; the cows are out during the day, and fed at night with bruised oats and hay.

We have observed this peculiar taste at different times during the last five years—generally strongest in autumn; but last spring it was peculiarly strong. After two or three days the butter is unfit for any purpose, and salting only makes it worse.

I have hitherto believed that it was caused by some herb

or grass; but there is so little pasture now, and the cows so nearly dependant on artificial food (hay and bruised oats) that I cannot attribute it to the grass.—COCHIN.

[We never tasted butter more rancid than the specimen sent by our correspondent. We can only suggest that the cream is kept too long before it is churned. We shall be obliged by any information on the subject.]

### OUR LETTER BOX.

COVENTRY SHOW (*J. W. T.*).—As this Show was in no way made public, and is now long past, it is needless to criticise what the committee considered not of sufficient importance to be made known.

BATH AND WEST OF ENGLAND SOCIETY'S POULTRY SHOW.—This will be at Hereford in the June of this year. The prizes are very liberal, and cups are given as additional rewards, as well as sweepstakes. Prize lists, &c., may be had of Mr. Pitman.

HATCHING TEMPERATURE (*A. W. M.*).—105° of Fahrenheit's thermometer is the heat for hatching hens' eggs. How is it possible for us to say whether eggs from a farm-yard will hatch, when we know nothing whatever about the yard or its management?

WHITEHAVEN AND WEST CUMBERLAND SHOW.—"Jas. Wood," not "Jas. Wood," won the first prize for Cochins-Chinas.

SPANISH HEN ROSE-COMBED (*Tyro.*).—There can be no purity in Spanish where a rose-comb appears. If the peccant bird is akin to those that appear pure, we should be nervous about the produce.

PRODUCING BANTAMS (*C. S. J.*).—Having made up your mind what breed you wish to introduce into the Bantam classes, choose the smallest male you can find having the attributes of the breed most strongly developed; put him to a large Bantam hen approaching as nearly as possible to himself in shape and colour, and guiltless of points that would disqualify the progeny in the father's class. If your space permit, and you are willing to take the trouble, reverse the above, take the smallest hen of the breed you wish to make, and the largest Bantam cock of proper colour, &c. The next year you will have to choose your smallest birds, but those most promising in points and character, and you must put them together. You will also put the original father with his daughters, and mother with her sons. This will give you each birds that by judicious selection for breeding you will have a breed. All such require re-pairing and strengthening now and then. There were three pairs of beautiful Cochins Bantams at Birmingham.

COCK'S COMB TURNED BLACK (*E. F. M.*).—Cocks' combs turn black from being chilled, from sickness, and from poison. There has been no weather severe enough to cause the first. The second may arise from over-feeding or improper food. In the first case, the food often remains in the crop. Warm water should be poured down the throat frequently, and no more food given till the crop is empty. This should be followed by a dose of castor oil; then soft food should be frequently given in small quantities till the comb is red and the bird cheerful. In case of sickness, castor oil is still the best remedy, a table-spoonful is a dose. When the comb becomes quite black, it is sometimes necessary to resort to bleeding. A small incision should be made, or the tip of one point cut off, but in either case care must be taken not to disfigure the bird.

DORKING HEN WITH CHEEKS SWOLLEN (*K. R.*).—Foment with warm water. Give a table-spoonful of castor oil, follow by two pills of camphor, and feed on bread and ale. Seven or eight Dorking hens and one or two cocks. As many Cochins and Brahmas as you like.

"F. C."—Next week.

ROUP (*K.*).—Sixty hens are a great number for two acres, more than the land will profitably carry if they are Dorkings, especially if the chickens have to be reared on the same ground. It is quite true that it becomes tainted, but we think not to the extent people fancy. There can be no doubt that fresh ground is very beneficial to chickens as regards growth and constitution. It is often the case that a piece of grass handy in situation can be hired for a small sum after the hay has been carried. This is old in summer, and if earlier the hen may be kept under the rip till she lay again. Scatter the chickens over the ground as much as possible. Kill any very bad cases of roup. Feed well on bread and ale. Put lumps of camphor in all the drinking-vessels that are in use, and see that the houses are clean. Leave doors and windows open all day.

JARS FOR PRESERVING EGGS (*An Amateur, Old Subscriber, and Others.*).—Mr. Geyelin's agent, Mr. J. Melville, 20, Glaskin Road, South Hackney, London, will undertake to supply the patent air-tight jars for preserving eggs, as the manufacturers will only sell to the trade. Prices must depend on the size of the jars. The carriage to Lancashire per rail is about 2s. per cwt. The artificial vermin nursery will be fully described hereafter.

COVERING FOR BEE-HIVES.—A gentleman from Wandsworth writing in these pages a few weeks since gave a description of a covering for bee-hives. My employer would esteem it a favour if I could be permitted to see these coverings, so that I may get some manufactured on the same principle.—THE GARDENER, *Sidney Lodge, Wimbledon.*

### LONDON MARKETS.—JANUARY 16.

#### POULTRY.

Christmas and New Year's days are passed, our country senders have done holiday-keeping, and a moderate but regular supply has again begun in poultry. Pheasants are still far in excess of the demand. We have never in our experience seen so many in one season. The mild winter should make early poultry plentiful, and we hope we may look forward to a prosperous year for buyers and sellers.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 44.8°, and its night temperature 41.9°. The greatest heat was 57° on the 29th, 1863; and the lowest cold, 8°, on the 31st, 1857. The greatest fall of rain was 0.90 inch.

THE MODERN PEACH-PRUNER.

THE LONG AND CLOSE SYSTEMS—PRUNING FOR THE OPEN AIR AND ORCHARD-HOUSE.

INTRODUCTORY REMARKS—No. 1.

It is probable that more books have been written on the subject of the cultivation of the Peach than on that of any other fruit. The Vine alone may claim a rivalry in this respect. In both cases this is not at all surprising. The culture of both is laborious and expensive, and the market value of the produce, when successfully grown, only adds to their popularity. We may, therefore, safely conclude that the subject of Peach culture possesses a general and undiminished interest. The recent introduction of glazed structures, tending considerably to augment the varieties cultivated, and thereby to add proportionately to the general knowledge of the habits and properties of the Peach, has given an immense impetus to its culture. By this means this noble fruit is brought within the reach of a class of growers who otherwise would never have been able to obtain it. In proportion to its dissemination is the demand for increased information as to the best method of growing it well and profitably. It is true that there is no lack of works treating of this subject. The only question is, Do they entirely satisfy the progress of the day?

Since many of them were written the varieties cultivated have multiplied immensely, many of these varieties being semi-tropical in their habits, and unsuited to the older modes of training. Many fine Peaches and a very large proportion of the Nectarines now known, it is impossible to fruit in the open air. No one at present can foretell what combinations may result in the future, nor how much influence glazed structures peculiarly adapted to the habits of the Peach may ultimately have on its general cultivation. One thing, however, is certain, and that is, that the modern method of training must eventually supersede the old system. Nay, more, the object of this treatise is mainly to attempt to show that the peculiar treatment required by trees under glass is well adapted for trees against walls in the open air. Certain very important modifications suggested by the climate of England being observed, the writer is quite confident, fortified by his own long experience and success as a Peach grower, that the new system which he proposes will be found practicable, and suitable to open air as well as to orchard-house training. It is with this idea that, in the present series of papers, it is proposed to give an outline of every system of Peach culture, ancient and

modern, reserving to the newest experience on the subject the more detailed portion.

There is no lack of materials to select from. On the contrary, the abundance of authorities is extremely embarrassing. A selection will, therefore, be placed before the reader, adapted to the wants of the subject.

In reading through the works of the older writers on the Peach it is impossible not to see how, while evidently well knowing their subject, they fail to make it intelligible to the beginner. In this was the cause of their failure. The instructions given presuppose an acquaintance with the subject, which knowledge was not really existing. In consequence, the rules laid down were best adapted for clever gardeners, and those only who were of a certain habit of thought. In those days there was little scope for the amateur. Trees were budded on stocks calculated to last the lifetime of the buyer; glass was expensive; many things now in common use were unknown. One single tree, chosen from half a dozen established sorts, was spread over a vast number of square feet of trellis. How was the amateur to experimentalise on such valuable stock by the light of the vague and general instructions which were then current? We all remember our fathers' gardens—those expensive walls—the grand old trees clothing them, "*tant bien que mal*"—our youthful awe and veneration of the dogmatic and self-asserting artist who presided over them. How could we, fresh from Oxford, dare to suggest any deviation from the old routine? Aristotle knew very little about Peaches, and, probably, if they ever existed in his day, called them "Persian Apples." Pliny, that great observer, was far better acquainted with their taste, but how few was he able to choose from! So that the gardener, practical as he was supposed to be, had it all his own way; and truly, in the then state of Peach culture, it was the safest plan for our parents to adopt.

Remembering these things, let us take up some old writer on the Peach, and it will at once be evident how he writes only for the initiated, and how little these could understand such vague rules. Still, in justice to these writers, let us always bear in mind that they were well acquainted with their subject, and only erred in expressing their thoughts indistinctly. But their great want was woodcuts to illustrate their meaning. In this consisted the great advance made by modern writers. Every cultivator of the Peach now knows that all Peach shoots are not alike, and he knows it by means of these invaluable illustrations. The modern books on this subject, then, are chiefly remarkable for detail and consequent classification. The French excel in this branch; the national taste lies this way. From a subdivision of property, under a magnificent climate, and having a varied soil, each Frenchman aspires to become a possessor of the land, and it follows that he loves it, and makes the most of it. Whatever may be said about agriculture, this subdivision of property favours gardening. The French mind is essentially given to detail, and highly adapted to organise. These are valuable qualities when applied to horticulture. Their books on the subject are,

therefore, admirable and deserving every praise. Nor is this all that is done. Professors, of well-known names, give courses of sound instruction on the theory and practice of pruning. These invaluable schools are attended even by ladies. The writer has derived much benefit from them; when shall we see similar courses open in England? We have learned men, second to none, deserving, too, of more honours than the country has as yet given them. When shall we see diplomas of various degrees given only to such gardeners and amateurs as pass their examinations satisfactorily? We live in an age of progress, and of rapid transition. Time is very precious. Horticulture has made immense advances in every way but recently.

The aim, then, of these papers is to give assistance to the amateur, and present to the mind, at one glance, the various modes of Peach culture.

The latest system differs much from that first used, and the cause of this is, no doubt, owing to the introduction of orchard-houses. In these one system alone obtains—the close pruning of shoots. While, therefore, it is necessary to make great allowance for the exigencies of open-air culture, there is really no necessity for following, in the latter case, any other way. To adapt close summer stopping, joined to close winter pruning, to the open wall, would be to simplify the whole system of Peach culture. Could this be well shown to be practicable, it would save much valuable time; and as the effect of close pruning is to increase the number, both of leading branches and of bearing shoots, it is evident that by that pruning space is saved and produce increased. The ancient plan was essentially based on “long pruning,” and experience shows that this has serious defects. In avoiding this error, others have fallen into the unnecessary and unnatural plan of summer shortening and disbudging.

It is the conviction of the writer, based on long practice, that the system of long pruning is unsuited to the present day. It will be shown, in the proper place, where alone it should be applied. The other methods, which are derived from it, are made, by the additions necessary, tedious and complicated. On the other hand the new method is simple, natural, and highly successful. The reader will, however, at least have this advantage, that he will be able to judge for himself, and select that which he prefers.—T. COLLINGS BRÉHAUT, *Richmond House, Guernsey.*

### DRAYTON MANOR,

THE SEAT OF SIR ROBERT PEEL, BART., M.P.

HAVING arrived by rail at Tamworth, the first object that attracted attention was Tamworth old castle, seated on the declivity of a hill, with the river Tame at the foot winding along through the valley. Drayton Manor is two miles from Tamworth. There are two entrances, the first is the more private, with a lodge on the right, then through a grove and over a bridge, with the water musically chafing its course over boulders and rocky ground. The other entrance, about a quarter of a mile on the Coleshill road, is the principal one, and has a neat stone-built lodge and iron gates.

The drive leads some distance through an avenue of Limes backed by large Holly trees and plantations, and through the open park, with the surrounding scenery well varied by clumps and belts of mixed forest trees, with distant views, three of them over the lakes, and of the mansion conspicuously seated on rising ground. Passing by the pleasure grounds and entering by the kitchen-garden gate, I directed my steps to a neat Gothic cottage, the residence of Mr. Ballingall, the head gardener.

I am happy to observe that where recent improvements have been made at various residences, the first object has been to erect a suitable dwelling for the head gardener. At Lady Holland's and at Oak Lodge, Kensington, at Coombe Abbey near Coventry, at Hanbury Hall near Droitwich, and at Arle Court, Cheltenham, very good garden houses have been erected. They are of the Elizabethan or old English style. The leading feature of this style applied to cottages is the dispensing with broken lines. The house is composed of different parts, projecting at right angles from each other, with also a projecting porch, and the outset octagonal windows command views in three different directions. The gables

are enriched with pendants, and the doorways with ornamental dressings, and there are handsome octagonal chimney-stacks. All the forms which particularly mark the Elizabethan style may be wrought in the cheapest materials with comparatively little labour, a small portion of ornamental work tastefully disposed is capable of producing very considerable effect. The size of the cottages would lead one to suppose that there was no objection to the anti-Malthus principle, and that gardeners (I mean those that deserve the name), will not advertise “no incumbrance.” I recollect dining one day with a gardener and his wife, who were blessed with a fine rosy-faced chubby boy, and the conversation turned on the impropriety of some gardeners' advertisements. I shall never forget the offended dignity of the mother as she said, “Good heavens! to say that that child is ‘an incumbrance’ is an offence against God, and a disgrace to gardeners.” After a little reflection she concluded, “I suppose the men who advertise thus are only hewers of wood and drawers of water?”

The kitchen garden at Drayton Manor is divided into three compartments, in which are a range of vineries 180 feet long, in three divisions, the borders provided with bottom heat, troughs on the pipes, and cast-iron tables in front; a fruiting Pine-stove 60 feet long, the sorts are Queens, Smooth Cayenne, Enville, Prickly Cayenne, and Providence, and the compost sandy loam and charcoal; a Fig-pit 60 feet long, with Fig trees in pots, which had ripened the second crop in the season; a Peach-case 270 feet long, in three divisions, each division can be heated separately, and the trees looked in excellent health, with plenty of fruit-buds; also a Peach-house; a Cucumber-pit 42 feet long, the plants bearing in pots and in the beds—the large leaves denoted health and luxuriance, and the fruit was splendid. The principal sorts were Perfection, Telegraph, and Conqueror of the West. A plant-house was filled with specimens worthy of exhibition at the metropolitan shows. The following are the names of a few:—Chinese Azaleas, *Acacia grandis* and *A. Drummondii*, *Phenocoma prolifera*, *Eutaxia myrtifolia*, *Eriostemon buxifolium*, *Rhyncospermum jasminoides*, *Lapageria rosea*, *Lonicera aureo-reticulata*, *Aphelexis macrantha purpurea* and *A. macrantha rosea*, *Pleroma elegans*, *Euonymus japonicus variegatus*, *E. radicans variegatus*, *Elæagnus japonica variegata*, and *Oxylobium arborescens*. Besides the above there were an Orange-house, and houses for stove plants, Orchids, and Ferns. In these were fine specimens of *Cyanophyllum magnificum*, *Alocasia metallica*, *Maranta vittata* and *regalis*, *Croton picta*, *C. angustifolia*, and *C. discolor*, *Dracæna terminalis picta*, *Allamanda Schottii*, *Stephanotis floribunda*, *Begonias* of fine foliage and flowering varieties. In the frame ground were Pine-pits, fruit-room, Mushroom-house, &c. Upwards of 3000 Strawberry plants in pots were in the best condition for forcing, the sorts were Black Prince, Keens' Seedling, British Queen, Oscar, and Sir Charles Napier. All the houses and pits in this extensive and well-kept establishment are heated by hot water.

Drayton Manor house is built in the Elizabethan style, having the usual appendages of turrets, towers, and terraces. The building is of smooth ashlar freestone, and was built about twenty-six years ago from designs furnished by the late Sir R. Smirke. The east front consists of a central hall; a turretted corridor tastefully covered with Ivy connects the building with the offices on the right; and the left wing consists of the picture gallery and conservatory, the latter a costly and beautiful octagon building, and certainly one of the most complete structures of its kind I have ever seen. It forms a kind of nave and transept, in the centre of which stands a beautiful marble fountain and basin 14 feet wide. Its curvilinear roofs and dome are supported by handsome iron columns, fluted, and painted green and white, and the capitals and bands are gold and green; festoons of the rich green drapery of the foliage, wreathed with flowers, entwined the pillars and hung gracefully from the roof. Among them I observed *Cobæa scandens*, magnificent *Acacias*, and *Passion-Flowers* of various sorts. The ends of the transepts are occupied by groups of plants, and aviaries containing rare and beautiful-plumaged birds. From the centre and other parts of the roof are suspended extremely ornamental and massive hanging baskets well filled with drooping and other flowering plants, and four beautiful coloured chandeliers are hung round the fountain. At each

end of the naves are two richly inlaid stone tables and four large mirrors that give variety and magnitude to these lovely scenes. It is also adorned with rockwork, the crevices of which are planted with Ferns, the water trickling down from the top to the marble aquarium, with silver and gold fish sporting in their element. At each side of the conservatory and near to the picture gallery are grouped some healthy Date and Fan Palms, a beautiful *Aralia Sieboldi*, and some *Caryotas*. On ball nights, when it is open from the picture gallery and illuminated with its seventy-two gas-burners, the effect can be better imagined than described.

The genial warmth, the delicious fragrance, the fine forms and varied colours of the noble plants, the voluptuous stillness that prevails in this enchanted spot, only interrupted by the soothing sound of the gently falling water or an occasional chirp from the feathered inmates, lull the fancy into pleasing day-dreams. We imagine ourselves in the blooming groves of Italy, while Nature, sunk in a death-like torpor, announces the severity of the winter through the windows of this magnificent conservatory.

The next scene is the flower garden. It is formed in a sunken panel, and is surrounded on the east, south, and west by a broad terrace promenade in grass. The north side is bounded by a handsome Gothic terrace wall, furnished with correspondingly massive vases. The terrace promenade just mentioned leads from the conservatory to the end of the western boundary of the flower garden, and has in the centre, along the whole distance, a handsomely-wrought arcade of iron and wire trellis-work. This arcade is 12 feet wide and 14 feet high, having at the east and west corners circular pavilion-like domes, 27 feet in height by 30 in diameter, of the same material as the arcade. The whole is covered with climbing Roses, Honeysuckles, Clematises, Ives, *Aristolochias*, and *Virginian Creepers*. The above terrace promenade is about 30 feet broad, having on the outer boundary a low iron palisading masked by a closely-clipt Yew hedge, with a space of about 5 feet between the hedge and the arcade. From the grass promenade descends a gentle slope about 9 feet wide, a walk 12 feet wide is continued round the flower garden at the foot of this slope, and is bordered by parallel beds of various sizes. Similar beds run parallel with the centre walk which leads from the terrace. The interior part of the garden is divided into eight grass panels by a transverse walk, and again by minor paths, which abut on two circular bays in the transverse path, which are equidistant from the central walk. There are circular beds in the bays, and the eight panels contain geometrical beds. A beautiful spherical sun-dial stands in the centre of the flower garden, a pair of marble figures at the top of the central walk, and vases near the angles of the grass panels. Under the terrace wall, which forms the north boundary of the flower garden, is a noble border 140 yards long by 16 feet wide, which was planted in summer with a ribbon of gay colours, which very effectively relieved the massive masonry of the terrace wall. Looking from the stone terrace steps when the beds and borders are covered with the various sorts of Geraniums, Verbenas, and other choice plants, judiciously arranged as regards colours under the discriminating eye of Mr. Ballingall, I can well imagine the gorgeous effect produced. A broad walk winds from the south-west corner of the flower garden through shrubberies and borders of American plants, standard Roses, &c., to a mound, the slopes of which are covered with hardy Heaths, then to a flight of massive steps leading into the arboretum or pleasure grounds.

On the west front of the mansion is a terrace 100 yards long and 16 yards wide, and on the north side is the Adelaide terrace 120 yards long by 50 wide. Along the inside of this terrace wall are planted Junipers and round-headed Portugal Laurels, and three massive clumps of *Rhododendrons* occupy the centre of the grass lawn on this terrace. A broad terrace walk 164 yards long leads from the door in the picture gallery westward to a kind of terrace court, with a circular stone basin 60 feet wide, having a massive stone edging or cornice; a fountain 20 feet high plays from the centre of the basin, and on a distant mound is placed a finely-sculptured Venus. From the centre of the court descends a noble flight of steps having square stone kerbs, pedestals of the same material, and marble vases; another

flight of steps ascends to the mound. From the west front you see a well-kept lawn, on which stands a beautiful marble basin and fountain, backed by Portugal Laurels, Cedars, &c. All the walks on the terraces are decorated with beautiful white marble vases.

Drayton Manor is profusely enriched with the most charming of all garden ornaments—the terraces with their statues, and vases, and fountains, and balustrades, and steps, all of which rich accompaniments, by carrying the eye from the interior ornaments of the chambers to the garden, so connect the whole as to make them a pleasurable part of it. The want of colour, so necessary to the cheerfulness of some, is, at those seasons when flowers cease to bloom, compensated for by the courting of sunshine and by the lights which are constantly falling and playing about these architectural ornaments.

From the north terrace are extensive views through the park, with dappled deer in the distance, and a fine sheet of water enlivened with swans, foreign geese, and ducks; altogether it reminded me of the following lines in Thomson's "Seasons:"—

"Herds and flocks  
Drop the dry sprig, and, mute imploring, eye  
The falling shower. Hushed in short suspens?  
The plump people streak their wings with oil  
To throw the lucid moisture trickling off,  
And wait the approaching sign, to strike at once  
Into the general choir."

The park, with its lakes and the groups of trees, and the woods, with fine open glades winding out of sight, extends about a mile in that direction to the Great North Road.

The pleasure grounds and garden consist of about 50 acres, and are divided from the park by an iron palisading, inside of which is planted a Yew-hedge, which completely shuts out any view of the palisading from the pleasure ground.

The entrance from the park is ennobled by beautiful iron gates fixed on embossed stone pillars supporting handsome marble vases. The drive now sweeps through the pinetum, and thence into a circular opening near the front-hall entrance, gravelled and bordered by a round-stone kerb, from which rise several stone pedestals, bearing also handsome marble vases. On one side of this entrance on the close-shaven lawn stands a trophy of war—a Russian anchor and cable, brought from Sebastopol in 1855.

In the pinetum are many noble specimens of *Picea nobilis*, *grandis*, *Nordmanniana*, and *pinsapo*, also of *Pinus excelsa*, *cembra*, and several others, some beautiful *Cryptomerias*, and Golden Yews, the foliage of the last beautifully contrasting with the dark green of the Pines. Masses of shrubs, and various other trees, formed an undulating boundary to the north side of this portion of the grounds. What is called the American garden was planted in avenues some years ago by Mr. Barron with *Aracaria imbricata*, and *Pinus nobilis*, *P. excelsa*, Irish Yews, *Wellingtonias*, (one of them was 16 feet high, and well feathered to the ground,) and an undergrowth of *Rhododendrons* and other American trees and shrubs, with grass rides between.

A branch of the river Tame runs through the park and close to the pleasure grounds, and has been expanded into several large lake-like sheets of water, with cascades. The trees are not sparingly or indiscriminately scattered around the margin, but liberally in some places, for the sake of a contrasted mass of colour, or shade to relieve the brilliancy of the water, and with discrimination everywhere to mark the beauties and heighten the variety of the outline without destroying breadth of effect. It gives me much pleasure to bear testimony to the superior management and high keeping displayed by Mr. Ballingall in all, and even the most minute, parts of this first-rate and extensive establishment.

Lord Brougham's schoolmaster is abroad in every city and hamlet patronised by the noble of the land, and led on by the lights of the age. At the village of Fazeley I saw a placard announcing that the first lecture of the season was to be given at the new school-room, Fazeley, by George Skey, Esq., subject—"Things worth Knowing." N.B.—As all the expenses of the library and reading-room, over and above the subscriptions, are kindly defrayed by the Right Hon. Sir Robert Peel, the receipts for admission will be applied to the purchase of books.—W. KEANE.

## HARDY FERNS:

HOW I COLLECTED AND CULTIVATED THEM.—No. 8.

It was in Cornwall that I first became acquainted with the *Asplenium lanceolatum* growing in its wild state. I had had plants sent to me from the Channel Islands, but I had not succeeded in making them grow out of doors; and even in a greenhouse they could not be said to be happy in cultivation. No one who had seen *lanceolatum* only in cultivation would know it for the beautiful Fern, so graceful in proportion and healthy in colouring, when growing in soil and under conditions suitable to it. In its wild state *lanceolatum* is very variable. In the old stone walls round Penzance it may be found in quantities, stunted in size, and with an ill-natured look, as if it had come into existence upon the barren wall contrary to its own inclination, and being compelled to submit, it would at least do it with as bad a grace as possible. Here and there, growing in peaty well-drained soil, I have found it with its fronds measuring more than a foot in length, perfect in form, and in colour a bright dark green. From the vast quantities of plants in the wall, and the less number away from it, it would seem that some quality in the lime of the masonry was necessary to its increase.

Growing side by side with *Asplenium marinum* on the rocks of St. Michael's Mount, I found a very interesting variety of *lanceolatum*. At first sight I took it to be a variety of *Adiantum nigrum*; but its form was lance-like, its stalk much greener, and its habit of growth crisper and stiffer. I have shown the specimen to a good authority on Ferns, and it was declared to be *Asplenium lanceolatum*, partaking largely of the nature of *marinum*. It has retained its peculiar character for three years, and flourishes in cultivation as I cannot make either *lanceolatum* or *marinum* do. It grew on a cliff intufted with *marinum*. I could not reach it myself, but I got one of the sailors who rowed us to the Mount to gather it for me, and he called it *marinum*; but this it could not be. In growth it presents a compact tuft of shining dark green fronds.

The walk from Penzance to St. Michael's Mount is chiefly interesting from the quantity of rare and curious plants that are to be found on the low sandy marsh, along the upper part of which the high road runs. But the way to approach St. Michael's Mount is by water when the tide is full. The old dwelling-place of the St. Aubyns, placed on the pinnacle of a bold rugged rock, stands out from the blue waters beneath, showing itself clear and distinct against the blue of the heavens above, like the fortress of some enchanted princess accessible to fairies alone. As you near the miniature island a few cottages are seen on its tiny shore, and you are landed on a flight of steps that leads to the Mount.

Penzance abounds in beautiful country walks. It has, too, its Hyde Park or Cascine, where the fishermen, miners, and citizens, with their wives and children, assemble every Sunday afternoon in holiday attire, pacing up and down on a raised walk by the seashore, exchanging kindly greetings with each other. I have never seen this custom in any other place in England: it gives to Penzance the appearance of a foreign town on a fête day.

In the country walks you will find every field, and thicket, and hedge abounding in strange and curious varieties of *Scolopendrium*. I found some with the ends tufted and fringed—some with the margins crimped, and the spore-cases diverging from a line running all round the outer edge of the frond. In cultivation this latter Fern has progressed into stiff narrow fronds most curiously crimped, and the upper end divided into several forked tongues. I found several *Scolopendriums* approaching to *undulatum*, but they have not altered as much as the more monstrous forms. I have a little theory about *Scolopendriums*, the truth of which I have tested till it might almost be called a fact. When I have found a Fern slightly fringed at the sides, and have planted it by the side of a true *marginatum*, the inferior Fern shortly acquires the habit of its neighbour, and gradually becomes transformed into the likeness of its peculiar growth.

The transformation of Ferns is exceedingly curious. I have for some time been watching a fine plant of *Asplenium viride*, which is slowly becoming divided into two or three

forks at the end of the frond. The pinne also are acquiring a toothed appearance, in some cases being cut almost up to the rachis, till it approaches very near to *A. fontanum*, although the difference is still too marked for any one to mistake the one for the other. This plant of *viride* is a near neighbour of a fringed and forked *Scolopendrium*, and not far from *A. Filix-mas cristata*. I believe all *Scolopendriums* are improved by cultivation and by good society; but this acquired beauty has never for me the same charm as natural grace. It is like the difference between a learned and a clever man—between water pumped up from a cistern, the length and breadth of which you can measure, and the never-ceasing flow of a rivulet on which the sunbeams sparkle and die. Still we do not grumble at a cistern when we do not possess a spring, and there is much pleasure in watching all the changes of the *Scolopendrium*. They have one other great point of recommendation—you may find something new in them, some strange deformity which no one else has noticed before; so that each hunt after Hart's-tongue has a sort of arctic-exploring character about it.

*Asplenium marinum* grows in large quantities round the shores of the "Lyonesse." At the Logan Rock, which must be "done" with the rest of Cornish sights, *marinum* is to be found in fine large clumps; but the many visitors who make pilgrimages to the huge plaything do not leave much available for ladies' reach. The Logan Rock is said to be between 60 and 70 tons in weight, and so finely poised that even a woman's strength can set it in motion. I saw it rocking to and fro as I was scrambling for Ferns in view of a fine expanse of ocean, breaking into gentle ripples on the white beach of the bay beneath.

A most interesting walk takes you from the Logan Rock to the ancient church of St. Buryan, where the eye can take in at a glance all the peculiar characteristics of Cornish scenery, and many of the antiquities which abound in the neighbourhood. In the churchyard of St. Buryan there are two well-preserved and very ancient crosses, on one of which is a rude representation of Christ on the cross. Within the church is a curious coffin-shaped monument, round the edge of which is an inscription in Norman French to "Clarice the wife of Geoffrey de Bolleit," ending with the promise of ten days' pardon for all who pray for the lady's soul. This monument is the more remarkable, as all vestiges of gentle residences have long since passed away, and only a few poor cottages remain to mark the site of what once was a place of note.

The view from the church is wild in the extreme. Standing on the summit of the old tower, the eye roams over tracts of barren land golden with Furze; huge upright stone pillars lie scattered here and there in the fields around—wondrous monuments of the past, when the dark belief of the Druids held sway in the land. Beneath is the emblem of the crucified Saviour, at whose coming the mists of unbelief faded away; in the distance, shining far round, is the wide expanse of the Atlantic Ocean, with the islands of Scilly made visible by the gleam of a setting sun.

On this one excursion you may find *Osmundas* at Lamorna Cove, *Lastrea recurva* by the hedge side, *Asplenium lanceolatum* in the walls, *marinum* on the rocks, and all the common Ferns everywhere. Besides the Ferns, the district abounds in rare wild flowers, such as are not often found in England.

One of the most pleasant excursions from Penzance is to Cape Cornwall. The carriage must be put up at the small mining town of St. Just, which is situated about a mile and a half from the Cape. The rock juts out from the sea, bold, erect, and defiant, able to cope with, and to hurl back again, the angry waves as they rave at its base.

I have never seen such glorious waves as at the Land's End and Cape Cornwall. They seem imbued with some living power of evil, urging them on in mad fury to destruction. To the west of Cape Cornwall there are two dangerous rocks, called The Brisons, rising abruptly from the sea upwards of 60 feet at high water. I have seen these nearly hidden by the foam and spray of the waves as they break roaring against them.

But Cape Cornwall is the best in a calm. Descending by a steep path cut in the rock you enter upon a bay, into which the waters come lazily with a lapping lulling sound, gurgling round the boulders of rock, and swelling out the

beds of the streams which trickle from the heights. Gulls, with their soft white plumage, wheel in gentle flights above your head. The air is soft and balmy as in Italy; and if you will you may pass hour after hour in the delicious calm of perfect repose—repose unbroken even by a dream. But if you will, as I did, you may leave your companions and stroll on and on, peering into sea caves and old shafts of mines, till you light upon—not a gull or bird of any sort—but a lad, whose bright eyes shine with keen intelligence out of a copper-coloured face, and whose hands, face, and clothes are all of the same copper hue. A quick glance and a nod, and we are sworn friends. By-and-by we find a cave literally covered with *A. marinum*, hanging in rich clusters from the roof and sides, wherever the waves do not reach—not common *marinum*, but the true Cornish variety, with fronds measuring three-quarters of a yard in length, and the pinnae very narrow and very far apart. My young friend and I soon secured a basketful of beautiful specimens, conversing all the while on the people and things in the mining district. Wages were pretty good; but there was the old grievance of “tommy” shops and delayed payment, necessitating the running up of scores at the small shops, and the payment of large prices for inferior goods. In religion the miners were for the greater part Methodists, Bible Christians, &c., with a slight reaction in favour of instantaneous conversion, as produced by Mr. Aitken and his followers. I asked, “Was Mr. Aitken loved?” “Yes, indeed he was. There was no hour by day or night he was not ready to be at the service of the poor. He was good, and the Methodist parsons were good.” And so my friend patronised first one and then the other, and doubtless thought himself very good too. Thus conversing we came back to my companions, whom I left looking too sentimental for aught but lotus-eating, but whom I found devouring cake and sandwiches with the rapidity and destructiveness of locusts. The copper boy sat down on a rock and devoured too, giving to the picture a richer tone of colouring than even blue sky or white gulls could produce.

I never found the true Cornish variety of *marinum* excepting at Cape Cornwall. In cultivation it loses much of its individual character. It diminishes in length and in the narrowness of the pinnae, but it still preserves a certain peculiarity of outline sufficient to separate it from the common *marinum*.—*FILIX-FEMINA*.

## CULTIVATION OF THE MELON.

(Continued from page 46.)

### IN POTS.

This mode of culture is chiefly applicable where there are no frames, pits, or houses, for growing Melons, though these are produced with much greater certainty in such structures than in those which I am about to treat of. A person having a greenhouse may attempt growing a few Melons in addition to flowers. After greenhouses or pits are cleared of their occupants for the summer, there is often room which the owner does not know how to employ usefully; it may be that there is a fancy for fruit; there may be no Vines, or, if any exist, they are perhaps planted far apart, so that anything placed between them would obtain plenty of light. This is the house for Melons. It would not suit Figs; they would require to be in the house much earlier, and Peaches are the same: besides, such fruits take up room in winter, the Melons none, and they can be raised in the same bed as the Cucumbers. Directions for raising plants will be found in previous articles. Select a plant that has been potted singly into a 48-sized pot, stopped at the second rough leaf, and transferred as it grew into a 24-pot. Two shoots appearing from it the strongest is selected, cutting the other out, and training that left to a small stick, rubbing out the side shoots as they show. Having plants of this description by the first week in June, the first step is to prepare the house for their reception by removing such plants as Pelargoniums, Fuchsias, &c., that will shed their leaves if they have not a cool airy situation, only retaining plants that will bear a warm moist heat, as Cockscombs, and not a single climber likely to shade the Melons. This done, shut up the house, sprinkle the floors and walls, and shut the door.

When the plants are ready to be shifted, which is when they have filled the 24-sized pots with roots, drain a 13 or 15-inch pot well, not putting in too many crocks, but a few, and some of the roughest compost over them. Strong loam is best, though light soil, also that so strong as to be clayey, will do, only it must be used differently. If strong and clayey pot the plant lightly, covering the stem no deeper than the seed leaves, and press the soil lightly round the ball; if strong, but not clayey, squeeze the soil firmly round the ball; but if light, in addition to pressing the soil firmly, beat it firm with a pestle round the ball and sides of the pot, using the soil rather wetter than when it is strong. When potted it must be decided whether the shoots are to be trained to a trellis about 9 inches from the glass or upright to a stake. If the plant is to be trained in the former manner it may be placed in the house at once, a stake of sufficient length to reach the trellis being put to it, but if not intended for a trellis, stake at the time of potting, using a stick 4 or 5 feet long, according to the height which the plant is intended to attain. Take the plants into the house as each is potted, and every time the house is entered it should feel warm and close. Give a gentle watering, and do not water too freely at first, reserving copious waterings until the pots are filled with roots; and to guard against the soil cracking or leaving the sides of the pot, a little moss placed on the surface will answer perfectly. Keep the soil just moist by gentle waterings until the roots fill the pots, after which water copiously, yet not oftener than the state of the soil shows moisture to be necessary.

Syringe every available surface morning and evening with water of the temperature of the house, and on hot days sprinkle the plants overhead, and especially on the under sides of the leaves. This syringing should be diminished when the fruit or blossoms are setting, and also when the fruit is ripening. When the fruit is set and swelling every alternate watering may be of liquid manure, consisting of 1 oz. of guano dissolved in a gallon of water, or manure water slightly discoloured, but be careful in using the latter. When the fruit begins to ripen give less moisture, both at the root and in the atmosphere.

Very little air need be given Melons in such houses, for the heat being that of the sun is better for plants than artificial heat, yet a little should be given early in the morning, letting the thermometer determine the time; when it reads at 80° admit a little, and if the mercury rises to 90° all the better, only shut up early in the afternoon, or before the temperature falls below 85°.

Train the shoot up to the trellis, removing all buds until it reach it, and then stop at the eighth joint after it has attained that length, none of the eyes between these two points having been removed. So with the shoots trained upright to stakes, remove all the buds at the axils until the required height is attained, and then stop the shoot, leaving six joints. These throw out fruit at the first or second joint, and the process of stopping described elsewhere being attended to, the blooms will set, and two fruits will be as many as the plant can swell well and bring to maturity.

Owing to the frequent watering the plants are rather liable to go off at the collar. To prevent this the soil should be raised in the centre of the pot in order to throw the water towards the sides; but as in that case only the soil at the outside will be properly moistened, it is advisable to raise the soil at the rim also, and thus form a trench between the sides of the pot and the neck of the plant. It will be advantageous to plunge the pots when the air of the house is kept drier during the ripening process; for dry air deprives the soil too rapidly of moisture, and much watering deteriorates the flavour. It is, therefore, advisable to prevent evaporation by plunging the pot, or covering it with a mat, rather than water freely.

Fruit from plants grown in pots is certainly smaller; but what is lost in size is made up in quality, small or medium-sized Melons being the best flavoured, as the sap is more concentrated on the fruit through the check on luxuriance, which pot culture always exerts on the plants subjected to it.

### PROPAGATION BY CUTTINGS.

Though Melons are usually raised from seed, it is possible to fruit them in about half the time if propagated by cuttings. This mode is the most rapid and certain way of

obtaining Melons. The cuttings to be selected are the moderately strong shoots; those having the joints the closest together are the most desirable, and they should be the growing points. Such taken off with from four to six joints, the lowest two leaves removed, and the base of the shoot cut transversely below the lowest joint, will root in a few days if put in a compost of sandy loam. Insert them down to half way between the second and third joint, plunge the pot in a hotbed of 85°, with a moist, close atmosphere, and shade from strong light and sun.

When rooted they may be gradually inured to light, and the shoot must be stopped when it has made eight joints, the two buds or shoots from the two lowest joints being rubbed off. Prior to stopping the plants should be potted in 12-inch pots in rough, strong loam, as described for pot Melons, and the shoots trained upright to stout stakes, if it is intended to grow the plants in pots; otherwise when well rooted they should be planted out of the pots in which they were raised, or 24's, into beds prepared for them. These are not different from those in which Melons raised from seed are planted, only they are made all at once, and there is no after-earthing. The soil should be raised a little in the centre of the bed, forming a ridge its entire length, so that in watering the water may drain from the necks of the plants, or from the centre to the sides of the bed. The Melons are then planted along the centre of the bed at 1 foot apart, every other plant being taken to the front, whilst the others are trained towards the back. If the bed is not in proper order, it is useless to plant Melons from cuttings in it, for they are not, like those raised from seed, to be burned or roasted the first fortnight with a strong bottom heat, and afterwards starved for weeks into fruiting. Plants from cuttings must be planted in a bed in every way suitable for their growth—that is, affording a steady bottom heat of from 80° to 85°, and a sweet top heat of 65° or 70° by night. Slight shade should be given for a few days after planting.

The shoot from each cutting should be taken to the front or back of the frame without stopping, but if it lose the leading point all the shoots except that coming from the third joint should be removed, the part above cut down to it, and this shoot trained to the back or front. When the shoots have grown to within 6 inches of the sides of the frames, or have made six to eight joints, the point of each should be pinched out. This will encourage side shoots or laterals, which will to a certainty show fruit at the first or second joint, and they being stopped at the joint above the fruit this will set freely, and swell rapidly. The plants if watered occasionally with weak liquid manure, will produce from two to four Melons, each of about a pound weight, and of the most delicious flavour, by the time that those raised from seed will be about setting their fruit, presuming them to have been sown at the time the cuttings were inserted. I have known plants from cuttings transferred with the flowers set from six-inch or eight-inch pots, into beds such as are usually prepared for planting Melons, and in ten days they had fruit on them the size of a goose egg, which fully swelled in thirty days after planting, and in twenty more they have furnished ripe fruit.

An important point in this mode of growing Melons, is to plant out the cuttings immediately they are well rooted, which they will be in about a week, for if they receive a check, or are allowed to remain in the pots until the roots mat round the sides they will do no good. Whether grown in pots or planted out they should not receive any check, but be kept growing, potted immediately when rooted into their blooming-pots, or planted out in the fruiting-bed, and kept in a growing state until the fruit is ripe. The cuttings are best planted or potted when five days or a week old, and if they have female blossoms on the point of expanding, these are the plants to produce ripe fruit in seven or eight weeks.

There is no difficulty in getting the flowers of plants from cuttings to set, for they do so most freely, and though the plants may be but a few weeks old even from the seed, they seem to have arrived at that stage when their whole vital forces are concentrated on the production and perfection of the fruit, or, in other words, the propagation of the kind. Experience has taught us that the fruitful laterals are sent forth after the main shoots have been cut back. In a cutting

the effects are most marked and striking in Melons. The shoots are less gross, the joints closer and more compact, the leaves are smaller, the flowers much more profuse and free-setting, the fruit is earlier and smaller, and the flavour higher though less juicy. The duration of such plants is short, for the principle of growth is paralysed by the severance of the plant from its original root, new parts are called into action, resulting in precocious maturity, closely followed by early debility and death.—G. ABBEY.

(To be continued.)

## THE ASSISTANT SECRETARY OF THE ROYAL HORTICULTURAL SOCIETY.

I THINK there is great cause for complaint against the Assistant Secretary of the Horticultural Society, in not sending out the Numbers of its "Proceedings" earlier. I received mine on Monday last, and in them it was announced that a ballot for Orchids would take place on Friday next, but that it was necessary to apply for a written form on Tuesday the 17th. Now, to any governor living at a distance, this was impossible, as it was in my own case.—R. H., *Poles, Ware.*

[This is only one of many complaints, showing gross neglect on the part of the Assistant Secretary.]

## POTATO CULTURE.

LAST year I had the pleasure of taking several prizes for Potatoes. The way I grew them is simply this:—

My first lot I plant (weather permitting) as early in February as I can make it convenient, doing so on a south border richly manured. I cut all the eyes out of each set, with the exception of one or two, and bury the sets about 3 inches. I plant them 3 feet between each row, and 18 inches between the sets; and to protect them from the frost I shake a little offal hay over them.

That is how I grow my exhibition Potatoes; but in setting an ordinary crop the distance between each row is not more than 2 feet, and 1 foot between the sets. This is for growing what we call the "Farmer's Glory," or any other common variety of Potatoes. I water them now and then with a little salt and manure water. I should be very much obliged to any of your readers if they could give me any information as to the sort called the "Early King." It is a round Potato.—E. W.

## LIFTING THE ROOTS OF VINES.

IN THE JOURNAL OF HORTICULTURE of November 29th, page 430, I read an account of very successful Vine-improving. I mean that of the friend of "W. C.," who lifted the roots in September, and only lost one Vine, a Muscat. He has had better success than myself; but before I proceed further let me begin at the beginning of my story. I came here rather more than two years ago. There is a good extent of glass under my charge—viz., two vineries, a greenhouse, a plant stove, and a range of Melon and Cucumber-pits. When I first came, I was told that in one of the houses there was no fruit that year, in the other there was a sprinkling, but the bunches were very much shanked. I meant to lift the roots at once, but having some improvements on hand, and my time being fully occupied, I saw plainly I could not do them justice. My employer was very anxious to have them improved; but seeing I could not manage everything, we agreed to let them remain for another year, and I would see what they did; the result was the same as in the former year, only still less fruit, and every bunch shanking. I knew well enough that the roots were at fault.

In September, 1863, I lifted the roots, and renewed the border, proceeding as follows:—I had two assistants, apprentices; we took off nearly two spits of soil before we came to a root. I had previously examined the border, and found no roots within 2 feet of the surface; we then took out a trench in front, and began in the usual way to work back with a steel fork, and as each Vine was taken up, the roots were wrapped up in mats wet enough, as it rained more or less

nearly all the time they were up. I never saw such miserable roots; not a fibre was to be seen, and they were in a rotten state, and down amongst the gravel, I do not know how far. The border was taken out to the depth of 2 feet 10 inches, and the bottom being gravel, there was little necessity for draining, but I did so in order to make assurance doubly sure; for the garden slopes towards the front of the border, a walk going along the front, in which I noticed water standing after heavy rains. The roots of the Vines, I ought to state, are all outside; the border is 12 feet wide, and as long as the two houses, which are each 30 feet in length.

After the bottom of the border was regularly drained, six drains across, and one along the front as a main drain, it was sloped to the front, and then we put in a foot or nearly so of rubble stones, and above that a layer of turves, grass side downwards. Now for the mixture of which the new border was composed. I was not allowed any more turves than would cover the stones, but there were a few over. I procured ten or twelve cartloads of half-decayed couch grass, fine open stuff, and a similar quantity of turfy road-scrappings, and a load or two of lime rubbish. The old soil was very good stuff, it had been all put in when the houses were built, about forty years ago. I had to use a good deal of it, as I could not obtain enough of fresh soil. I put it in in layers—first a layer of the old soil, then one of the other stuffs, time about, till I came to lay the roots out. They were all carefully pruned, and nicely laid out, putting some fine rich soil over them. After we had put on another layer we gave a nice shower of water to settle the earth about the roots, and then finished off. The houses were shaded and syringed for some time. The foliage flagged and faded notwithstanding, and the wood was very imperfectly ripened. I pruned the Vines about the end of December, and cut out more than half the rods, leaving only two to each sash, and all the young ones coming from the bottom. I cannot tell what system was aimed at by my predecessors, it was neither the spur, the long, nor the short-rod system.

Now for the result. All the Vines broke but three, which are quite dead. Some of them made pretty good shoots, others indifferent, and others only burst their buds, and made a leaf or two. I gave no fire except in the months of October and November, 1864, to help to ripen the wood. I watered the border frequently during the dry summer we had, with pure water only. The wood is not very well ripened, and I have pruned them nearly close in again. I examined the roots when I was taking out the dead ones, and find some have made nice healthy fibres. I have given them no protection as yet, as I thought I would have to take them all out. May I look for any fruit this year? and will you advise me to assist them with a little fire, beginning about the end of next month?

I have a fine lot of young Vines of last year from eyes; they are in 10-inch pots, and most of them grew to the

length of 15 feet, but were long in ripening, as it was well on in February before I had the eyes. I intend to plant them among the old Vines, and have pruned them to the length of 4 feet, as they will require to be that to reach the first wire. I have a few for fruiting in pots, but will not start them for a month yet, as they were so long in ripening; they are in 12-inch pots.—J. H., *Nairnshire, N.B.*

[So far as we can see you have done the general work well. When the roots of Vines are so rotten and decayed as you describe yours to have been, it would have been better to have made a suitable border and planted young Vines at once. The fact that the Vines that did pretty well made nice fresh fibres, showed that the moving and lifting in favourable circumstances is a very good plan for renewing the health and fertility of Vines. You would no doubt have succeeded better if you had forwarded the ripening of the old Vines before taking up the roots. There would then have been less chance of flagging. That flagging should be prevented by shading, a moist atmosphere, and syringing. By such means some of our great gardeners have raised and replanted Vines in May and onwards. It is just possible that you would have succeeded as well by "W. C.'s" plan, and after removing the two spits of soil without roots have placed a little fine turfy soil and lime rubbish on the top to encourage the roots upwards. You say nothing of protecting your border in the winter of 1863 and 1864, though that would have formed an item of success if the soil had been warm enough to encourage a slow rooting all the winter. Unless the old soil was very good indeed it would have been better to have used only a little of it, even if you had only made a third or a half of your border at once. The old soil placed loosely in a heap would have been all the better of the exposure, and might when well aired have been afterwards used as part of the compost. You did right in allowing the Vines to break naturally without any fire heat; but we should have advised giving a little fire heat in May and June, with a corresponding moist atmosphere to encourage growth, and then again in dull days in August and September to hasten maturity, as for that purpose one fire then would be worth half a dozen in October and November. The fire heat in spring with a moist atmosphere and a little heat in the border might have made vigorous out of indifferent growth. The summer with us has been sunny and hot, and your crop next season will depend on the ripening of the wood where it is pretty good. We cannot say more of success in that direction. We would, however, advise planting fresh Vines where the old ones have done badly. You cannot err in making sure by planting plenty, as you can easily cut out when too thick. The system of pruning is of little consequence. Let the Vines be healthy and the wood well matured, and cut how you may you will be sure to get fruit if you leave buds. We would advise covering the border to keep out wet and cold at least, and let the Vines break naturally again.]

EXPLANATION.

Cloud.—This column gives the mean of three or more observations per day, from sunrise to sunset. Scale 0 to 10 (estimated). Force of Wind.—The average of extreme force during the day (twenty-four hours). Scale 0 to 12 (estimated). Direction of the Wind.—This gives surface currents

obtained by vane or smoke, from three observations per day, from sunrise to sunset. Thermometer in north aspect, 4 feet above the ground. Barometer near sea-level. Rain-gauge 3 inches above the ground, and near sea-level.—THE DOCTOR'S BOX.

## ROYAL HORTICULTURAL SOCIETY.

THE prominent feature on this occasion was the magnificent bunches of Grapes from Mr. Miller, gardener to the Earl of Craven, Coombe Abbey. The six bunches of Barbarossa which he sent weighed collectively 36 lbs; the largest was 7 lbs. weight, and about 16 inches long from the shoulders to the tip, and all the bunches were handsome, compact, and even in the size of the berries. The six bunches of Lady Downes' from the same exhibitor were also very fine, with large regular berries. Mr. Miller also exhibited a skilfully drawn plan of a portion of the gardens at Coombe Abbey which he has laid out, representing the fruit and kitchen garden, a long parallelogram with the forcing-houses on the north and east sides, the whole surrounded by pleasure-grounds. The extent is from 16 to 20 acres, but when finished these grounds will occupy about 40 acres. As a specimen of garden design this plan was highly creditable to Mr. Miller.

Mr. Bull of Chelsea exhibited a collection of Aucubas comprising a variety with leaves longer and more lanceolate than the common kind, a variety called elegantissima, with large leaves, of which the central portion was yellow, broadly margined with green, and the male and female plants of the species, the latter in berry. For the last-named, also for the collection, first-class certificates were awarded. From Mr. Bull came also an Elæagnus, brought by Mr. Fortune from Japan, and having handsome white-variegated foliage, and another called aureo-marginata, in which the leaves were dark green with a yellow margin. For the former a first-class certificate was awarded.

F. J. Graham, Esq., of Cranford, sent a seedling Russian Violet called the Czar, with dark blue flowers double the ordinary size. This variety, it is stated, has been in bloom for two months out of doors, and flowers most abundantly in spring. It promises to be an acquisition.

Of other objects, Mr. Aldred, Kilburn, sent *Lilium auratum*, seedling Cinerarias, one with variegated leaves, and Double White Primulas, for which he had a second-class certificate. A similar award was made to Mr. Ingram, gardener to Her Majesty, for six Chinese Primulas. Mr. Stedman, Thornton Heath, contributed Violets; Miss N. Ffarington, Wooden Hall, Lancashire, a dish of home-grown Almonds; and Mr. Bullen, gardener to E. Budd, Esq., Leatherhead, three good Queen Pines, for which he had a first-class certificate.

## RETINOSPORA OBTUSA AND OTHER CONIFERS.

I AM much obliged to Mr. Welsh for his statement confirmatory of the hardness of Japanese Conifers in the north of Ireland, but I am still at a loss to understand the cause of *Retinospora obtusa* being here yellow at the tips—in fact, in the case of small plants, the greater portion of them are of a bright golden colour, not the sickly hue arising from the shoots being unripened, as we see in so many things, but they appear as if it were the character of the plant to be yellow, instead of green, like the Golden Holly and some other trees. I have no doubt that this *Retinospora*, as well as its fellow, *R. pisifera*, will be found quite hardy; but so far as I can judge from what I have seen and what is known of *Sciadopitys verticillata*, it will never become a useful tree in this country. One that I have had for three years makes no progress whatever, or next to none, and some other growers report on it in a similar way. I am afraid that *Torreya grandis* will not prove hardy, which is much to be regretted, as it promises to be of better habit and quicker grower than most new things in its way.

I have not yet seen a good specimen of *Thujopsis dolabrata*, and would like to know if it is likely to assume the character of a tree. Most of the plants that have come under my notice, including one or two we have here, seem to require a stick and close-tying to make them anything like upright, while the stem does not seem to increase in thickness like *Cupressus Lawsoniana* and others, which, when in a young state, have a semi-pendulous character. I expect it will have to be coaxed into shape if it ever assumes tree-like proportions. When speaking of these matters might I ask if any one has grown *Araucaria Rulei*, and can report

favourably of it? Some time ago I heard of it exceeding *A. excelsa* in beauty and symmetry. Is this really so? and, as new Pinuses are so eagerly sought after, it would be well to let the merits or failings of each be made known by those who have had experience with them.

I am sorry I can neither confirm nor differ from Mr. Fish in his report of rabbits eating off the young shoots of Mahonias, but I will take more notice of them when the growing season comes round again.—J. ROBSON.

## PLANT JUDGES.

THE remarks made by your correspondent respecting the management of flower shows, appears to me to deserve the attention of all interested in floral exhibitions, and lest it should be thought an officious obtrusion in me saying anything upon the subject, I will state my reasons for so doing.

Last summer I was appointed one of the plant judges at a large exhibition in the north. I soon found that my colleague was intimate with some of the exhibitors and knew their plants, and the same remark applies to myself. On two or three occasions we differed as to which collection should have the first award; on each occasion an umpire was called into the tent, whose decision, of course, was final, and in each case he decided against me, the umpire, of course, having the same leanings as my fellow judge.

Now, I do not mean to impute unworthy motives, because that would cut both ways, although I may state that in one glaring instance the collection that was put second was about 50 per cent. superior to the first. What I denounce is the principle of having judges acquainted with the collections they are judging. They ought to be, as far as possible, strangers to the exhibitors and their products. I know in some cases this is almost impossible, more particularly at small shows; but in the case of large exhibitions, such as the one to which I have alluded, it would be much more satisfactory to secure men from a distance and unacquainted with the collections they adjudicate upon, and I have an impression that this course would give satisfaction to exhibitors.—BRUCE FINDLAY, *Botanic Gardens, Manchester.*

## OBITUARY.

THE LATE MR. WILLIAM COLE.—We much regret to announce the death of Mr. William Cole, of Fog Lane Nursery, Manchester, who has occupied a high position as a plant grower during a period of twenty-three years. Those who had watched him for the last three or four years, saw that hard work and mental anxieties were telling upon him. The up-hill work of establishing a large nursery business, and maintaining a world-wide reputation as a most successful plant grower and exhibitor, was no ordinary task, and, as with thousands of others, Nature gave way, but the name will long remain in the memory of plant growers. Erysipelas and fever laid hold of him, and after a brief illness a peaceful death awaited him. He died December 28, aged fifty-two. Originally following another pursuit, circumstances led him to adopt that of gardening, and he at once placed himself under Mr. Robinson, gardener to — Delafield, Esq., Tunbridge Wells, with whom he remained three years. He then went into Messrs. Cormack's Nursery at New Cross, and we believe Mr. Charles Turner, of Slough, was in the establishment at the same time. Both have become eminent, each taking a lead in the two sections of plant-growing, and continuing fast friends. In 1841 he went as gardener to — Lewis, Esq., of Blackheath, and here began his career as an exhibitor. Commencing with Fuchsias, and being encouraged by Mr. Lewis, he followed with Heaths, &c. In 1845 he became gardener to H. Collyer, Esq., of Dartford, and remained with him until Christmas, 1853. During that period he fought many a hard battle at Chiswick and the Regent's Park with the late Mrs. Lawrence, and being well matched, Mrs. Lawrence, who at that time stood high for plant culture, found in Mr. Cole sometimes a defeating opponent. As a sound, practical plant grower,

kinds may now be done. Should, however, some Provençe, Moss, and other summer-flowering sorts be required to bloom late, reserve a portion till April for that purpose. Should heavy snow or severe weather set in, Pinks and Carnations planted in the open borders will run some danger of destruction in those localities where hares and rabbits abound. Protection can be given by laying small pieces of Larch spray or branches between the rows of plants, and then placing other branches on the top of these. Air and light have free access to the plants, and as spring advances the coverings are removed; for, as vegetation commences, more palatable food in the shape of young clover, &c., will entice the rabbits and hares to feed at a distance.

#### GREENHOUSE AND CONSERVATORY.

The unsettled state of the weather lately, has called, and will probably continue to do so, for much judicious management in regulating the temperature. While cold, biting winds prevail much caution must be used in admitting air. It will be necessary to support a temperature varying from 45° to 50° by moderate fires. Naturally plants make little progress at this season, but they may be stimulated to unhealthy activity if attention be not directed to the regulation of the temperature; a forced and premature growth will for ever injure plants both in health and appearance. Repressing undue activity at this time will in no wise enfeeble plants, or prevent their perfect development at a later and more favourable season. Care must be taken that Camellias receive no check, or their buds will be endangered. *Brugmansia sanguinea*, a noble conservatory plant, demands similar attention.

#### STOVE.

Still be cautious in the application of more heat. For the Orchids it is far better, the year having only begun, that they start somewhat later, with a free growth than to make a premature and stunted one. Take every care that a due proportion of moisture is maintained in the atmosphere. Although the majority of this tribe require to be very dry at the root during the rest season, yet they enjoy and require a somewhat moist atmosphere, more especially if in a state of constant and lively motion.

#### FORCING-PIT.

Bring in a successional lot of bulbs, &c., and if not already done take all the hardy forcing plants under the protection of a greenhouse stage, or even a warm shed, or the frost may have them in its cold embrace at a time when you would wish to introduce them to warmer quarters. Apart from this, it is advisable to excite them gradually before they are introduced to the forcing-pit. Let the temperature be from 60° to 75°, with sunshine. Shut up early with a moist atmosphere, but give a little air, if possible, before leaving the fire for the night.

#### PITS AND FRAMES.

Sow on a gentle hotbed for pricking-out Cauliflowers, hardy Lettuces, Red Cabbage, and a few Horn Carrots. See that Cauliflowers in frames and hand-glasses have proper attention in giving air, removing decayed leaves, stirring the surface and placing dry earth or dry charred refuse among the plants.—W. KEANE.

### DOINGS OF THE LAST WEEK.

#### LABOUR POWER.

GENERAL work very much the same as last week, with the addition to attending to many little matters too numerous to mention. Sometimes people write to us inquiring what labour power they ought to have for such a sized garden, telling us the old story about the man to the acre. We are always forced to give a very qualified reply to all such questions. We have seen an acre of garden-ground so managed, that a single man all the year through must have had a comfortable time of it, so comfortable that like many of our forefathers when John Frost asserted his supremacy, he might go and enjoy himself with any sport that was then in progress. We have seen other gardens of less than an acre, so laid out, supplied with glass, &c., and so much wanted from the small space, that three or four times the labour power would leave enough for every one to be kept actively at work. A garden, too, not only cropped, but

kept so as to be passable, is a very different affair from keeping everything in first-rate order. We recollect very well of two gardens very much alike, except in the matter of keeping. In the one two men were kept, in the other four. In the first the walks were rolled once or twice a-year, and a little roughness was no objection, nor yet a few weeds, if they did not assume giantlike proportions. In the second case the lawn was rolled every morning in summer with a light roller to scatter the dew, when there was any, that the ladies might walk earlier upon it without wetting their thin-soled slippers; and the walks were generally rolled at least three times a-week, and so free of a leaf or a weed were they kept, that the proprietor if he noticed a weed anywhere above 1 inch in height, was almost sure to give himself the trouble of going after it, pulling it up, and laying it down very carefully in the centre of the principal walk, just to act as a quiet hint to the gardener. That employer was a noble-hearted man, and though as great an enemy to idleness as ever lived, would at the same time have been horrified at any in his employment being overworked, or even working as hard as he did himself in his commercial undertakings; and yet though the men were chaffed by their neighbours for having so little to do, it was well understood on the whole that the four men worked sharper than the two in the neighbouring garden.

A number of little matters also, especially if attended with various things foreign to the garden, make all the difference in the labour power required. A gentleman not so long ago, after telling us all about his garden, though perfectly satisfied, thought he might manage with much less labour power; but whatever we thought then, we formed a very different opinion when we learned that men and boys were taken from the garden to beat for the young gentlemen whenever they went shooting—that they had to prepare wood, carry coals to the different places in the mansion, pump water, attend laundry, run all sorts of messages, &c., attend and do all sorts of little jobs at all times and all seasons. No plan can be more wasteful of labour power. It is not only the time thus lost to the garden, but the men get unsettled and unfitted for garden work just in proportion as they are so employed, and to the number called upon to engage in such employment. If there is not enough work for an odd man to attend to all such matters, it would still be advisable to have one man in general for such work, and place him at the garden or farm to fill up the time he was not wanted at the house, &c. It will only be safe, however, to count very little on such extra services out of doors. Many gardens that would be in first-rate order, and a source of happiness and comfort to all concerned, are turned into scenes of endless worry and annoyance merely because the gardener can never depend on his labour. Whatever the amount of that labour, it ought to be kept to the garden as a general rule. Of course there are exceptions and emergencies when everybody would only be too glad to give a helping hand; but we know full well that no garden can be conducted satisfactorily and economically when everybody about an establishment can take and get what help they may think they need from the garden-men.

#### GARDENERS' DWELLINGS AND HEALTH.

We class these together, because the dwelling more than the nature of the employment, exerts a great influence on sanitary matters. Sudden changes from a hothouse to a frosty temperature may be guarded against by clothing and muffling up. Damp at the feet in dull, muggy weather, may be neutralised by wooden sabots, or india-rubber goshes, not worn longer than necessary, otherwise they will heat and draw the feet, and by the confined perspiration do more harm than good. But no care can ward off the effects of low, damp, shaded, small, unventilated houses. Few can give ventilation in winter, and at the same time avoid cold, cutting draughts. Small rooms are, therefore, apt to be very unhealthy in winter, as the more the heat, the more will the atmosphere be rendered impure by the processes of combustion and breathing, more especially if the walls or floor be damp. In a large room, the fire will form a good ventilator, with the help occasionally of opening the door for a few minutes. And the same with bedrooms. Instead of having in winter to open door or window at night in a small bedroom, it is every way much preferable to have

a good-sized room, not crammed with furniture, and a good-sized open fireplace to the chimney. It is hardly possible to breathe an impure atmosphere in the latter circumstances, it is scarcely possible to breathe a healthy one under the first conditions. The non-ventilation and the free ventilation of such small places, we believe from experience to be alike dangerous, and if any openings besides the chimney are made or given for air, these openings, in winter at least, should be covered with thickish gauze, that the fresh air may be warmed before it reach the respiratory organs. We should here take a lesson from the old gardeners with their early Cucumber-beds in winter. They would never have slid down their sashes, and let the air enter all at once. They tilted up the sash very carefully, and hung a piece of matting or gauze over the opening. No keen north-easter was allowed to touch the leaves of their plants until mollified by passing through the hot, moist air seeking an outlet.

There is hardly a possibility of convincing young people of the importance of such little matters. Young men with perspiration freely flowing from every pore, stripped of their upper clothing, will come out of a hothouse without waist-coat and coat, and stop out for half an hour, and will tell you when remonstrated with, that it never hurts them a bit. That may be quite true. Neither did we feel it at the time, but many an aching rheumatism we have had since, as the direct consequence and punishment for such imprudence, and we would like to warn our young friends that law-breaking and law-vindicating generally follow each other. Just let them try and find out how many thus reckless of heats and colds, have lived over forty and fifty years, and of these again how few are there who from rheumatism and other ills have not had reason to regret their youthful carelessness. The punishment for such carelessness may not come for years, but it will be none the less certain and severe at the last.

We have also met with brethren, ripe in years and wisdom, who lived in small lean-to rooms behind the range of hothouses, and though not liking the place made the most of it, and were thankful that they themselves escaped with so few illnesses, and that though obliged to crowd, they were doubly grateful that their children as a whole were so healthy. The heads of the house from their hardy bringing-up had been constitutionally seasoned, and the young members of the family had all the strength and buoyancy of youthful vitality, and we might be thought to lift a warning voice in vain, but for the striking fact, that of the seemingly healthy children thus reared, that we can bring back to our recollection few, few indeed of them, saw their twenty-fifth birthday. The seeds of consumption and other diseases were too surely sown in their young frames in these dark, damp, shaded rooms.

Though little from home for two years at least, it is gratifying to find great changes for the better in this respect. Of course few gardeners could expect such an elegant house as that inhabited by our friend Mr. Robson, built for his comfort by his kind employers, or such a house as at Trentham, and numbers of other places; but there is a vast descent from such little palaces to such wretched lean-to's as are sometimes yet to be met with, though often existing without the knowledge of the proprietor that things are at all so bad. Between these two extremes there are many mediums of comfort, and to the credit of the gentry and aristocracy of England the time will soon come when the last of these unhealthy places shall be used for something else than human habitations. Let it be laid down as a rule that every living-room to be healthy should have the chance of the sun sending its rays through the windows at some time of the day.

#### PREPARING FOR POTTING.

In dull wet days had all the garden pots thoroughly scrubbed with warm water. In general we like pure water best. In the spring when filling the same pot over and over again, we are not particular with the outside; but we never like to see a pot used twice without washing the inside. Of course, when the plant is likely to remain some time in the pot, the outside should also be thoroughly cleaned, as nothing looks more woe-begone than a pot covered with greasy slime outside, even if the plant in it should be pretty fair as to its appearance. All pots, too, at

this time are best under cover, as the alternations of frost and thaw, and rain and snow, are apt to crack them when exposed. When properly washed we never make any difference between old and new pots, only when new ones are used for the first time for a particular purpose, it is a good plan to soak them for ten minutes and then dry them again before using. If this is not done, the pot for some time is apt to rob the ball inside of its moisture. This moisture-stealing is moderated by first soaking the pots. No pots should be used until they are dry, as if filled when wet, the ball will not come out so clean afterwards. Using wet pots is as bad a practice as digging stiff soil in a wet day.

#### GETTING SOILS UNDER COVER.

This should be neglected by none of our young gardening friends who aim at success. The soil should be well aired and dried, for the potting-time fast coming on us. The fine, crisp, aired soil often makes all the difference between success and failure. It will be a great advantage, too, if soil is so far warmed as to be rather warmer than the soil in the pot, the plant in which is to have more room. We have known window gardeners whose great success was partly owing to shifting their plants in February and March in soil that had previously been nicely warmed and aired in a box placed on the hearthstone of the kitchen. We have seen their neighbours fail of success because they used cold claggy soil in March, even though they watered immediately afterwards with water at 80°. This was freezing and next to parboiling by turns, and then giving a plant that required a nice open soil the surroundings of a marsh plant. Hardly any treatment afterwards will make that soil kind and comfortable to young plants.

Having skipped particulars this week, we will conclude with two words of advice to our good friends the window gardeners. *Avoid all checks and sudden extremes.* The above cold, claggy soil would be a sudden check to the young rootlets of the plant you shifted. If the plant was taken from the window of a sitting-room, and thus shifted, and then left with others to stand in some cold shed or outhouse until you have a few more done that you might take them all in at once, ten to one the whole of the points of the roots are killed, and the plant must begin and make a fresh effort, and most likely the first teaching in the way of experience will be shoals of insects attacking the crippled plant. If you must take a plant or two from the room to give them more pot room, keep them out as short a time as possible. They want a greater stimulus to growth immediately after potting than before; therefore, every minute they remain in a colder place is just so far injurious to them. Hence the importance of the kindly aired, warmed soil. Hence, too, the importance of watering the plant with water about 70° some time—say an hour or two at least before shifting it into a larger pot. If the fresh soil is neither wet nor dry, and placed pretty firmly round the ball, it will want little water except just at the side of the ball, before the fresh roots are running freely into it. Flooding with water at this season is attended with two disadvantages. First, It saturates and makes a marsh of the fresh soil unoccupied by roots, and then the rapid evaporation in a warm living-room cools the soil round the roots. For one plant that is lost from dryness in winter, dozens are ruined from over-watering. Secondly, Keep leaves, stems, as well as pots and saucers clean. A dry, soft brush to remove dust, and then a soft sponge to use with soft water about 65° or 70°, are the simplest and best modes for cleaning both upper and under sides of the leaves, and the stems. If plants are not inconveniently large, place a cloth over the top of the pot, place your hand firmly on it, and then turn the top of the plant, and swing it well in a tub of clean water. Where the plants are large and the leaves small, it is often better to syringe the plant well, run the fingers through the upper and lower sides of the leaves, and then syringe well again with clean water. Such extra care on your part will be rewarded by healthy foliage, and freedom from insects.—R. F.

#### TRADE CATALOGUES RECEIVED.

R. Parker, Exotic Nursery, Tooting, Surrey.—*Catalogue of Agricultural, Flower, and Vegetable Seeds, Fruit Trees, New Plants, &c.*

B. S. Williams, Paradise and Victoria Nurseries, Holloway, London.—*Descriptive Catalogue of Flower and Vegetable Seeds.*  
 Charles Turner, Royal Nurseries, Slough.—*Catalogue of Seeds for the Kitchen Garden, the Flower Garden, and the Farm.*  
 Smith & Simons, Argyle Arcade, Glasgow.—*Cultural Guide and Descriptive Seed Catalogue.*

COVENT GARDEN MARKET.—JANUARY 21.

Supplies good, and quotations nearly the same as last week. Apples are still very abundant; good dessert Pears scarce. These consist almost exclusively of Glou Morceau, Beurré de Rance, and Ne Plus Meuris. Forced Asparagus can hardly be had; but of Sea-kale and Salads there is a good supply.

TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

SALE OF APPLES (*Cottager in the West*).—Only choice named varieties realise a high price among London fruiterers. You had better sell yours to the fruiterers in the towns nearest to you.

CORDON-TRAINING (*A Constant Subscriber*).—We could not explain sufficiently without illustrations. Buy a little volume entitled "Cordon-training of Fruit Trees," by the Rev. T. Collings Brébaut. It is published by Messrs. Longman & Co.

GRAPE VINES (*A Grape fancier*).—You had better pot your two-year-old Vine immediately, injuring the roots as little as you can. Whether a White Grape Vine be in-ched on a Vine bearing Black Grapes, or Grapes of its own colour, is of no consequence. The Trebbiano is totally different from the Portugal or White Hamburg Grapes sold by grocers.

AURICULAS IN A ROOM (*Neophyte*).—The Auriculas will do very well in a cool room where they can have light. Grayson's Asparagus is considered the best, but we think the treatment makes all the difference.

TWELVE HYBRID PERPETUAL ROSES FOR POTS (*Idem*).—Caroline de Sansal, Comte de Nanteuil, Géant des Batailles, Général Jacqueminot, Louise Peyronney, Louise Odier, Jules Margottin, Mrs. Charles Wood, Olivier Delhomme, Triomphe d'Alençon, Victor Verdier, William Griffiths.

CLIMBERS FOR WALL (*Idem*).—Jasminum nudiflorum; the common white Jasmine; Escallonia macrantha, E. rubra; Chimonanthus fragrans; Ceanothus azureus; Aristolochia Siphon; Lonicera grata, L. japonica, L. reticulata, &c.; Clematis Hendersoni, Sweet-scented Clematis, &c.; Periploca græca; Virginian Creepers; and Tea Roses.

FRUITS FOR QUEENSLAND (*J. G. Cribb*).—Your letter of the 18th October has been received, and also the transfer of it. Not more than two or three of the Apples can be had in this country. We have all the Pears except Oct, about three of the Grapes, and all the Peaches but one. Thank you for your interesting letter.

COMMENCING VINE-FORCING AT INVERNESS (*J. M.*).—To start in January or February so far north you should at least, in such a house, have six pipes, instead of four. The two extra pipes will soon save their expense in fuel. It is a great waste of fuel to be forced to make the water boil in the pipes at such a distance as 90 feet from the boiler. It will be better every way if the water is rarely hotter than from 170° to 180°. With your present four pipes in such a span-house, we think from the 18th of February to the 1st of March would be quite time enough to begin to force. Then you may have Grapes in the middle of July, or thereabouts, if you have a few early kinds, as Sweetwater, Muscadine, and Frontignan.

GARDEN WALLS (*An Old Subscriber*).—The height of the wall would depend on the laying out of the acres. If a square, or a parallelogram, with the shortest sides to the east and west, then the north wall might be 12 or more feet high; but it would be as well if the south wall were not more than 9 feet. In a narrow garden a high south wall keeps the half of the garden shaded. A nine-inch solid wall would do up to 9 feet in height. If higher 14 inches would be better. A hollow wall would be the most equable in temperature and in dryness, but it must be well tied by an experienced bricklayer, or it may not be stable enough for railing, ladders, &c. In previous volumes we have explained how the tying is systematically done, and a good bricklayer knows all about it. Built well in this way, a 14-inch wall will cost few more bricks than a solid nine-inch wall. Such new walls should be studded or wired.

GRUBS DESTROYING STRAWBERRY PLANTS (*M. E. G.*).—The white grubs with red heads are the caterpillars of one of the Ghost moths (Hepialus sp.), and the darker grubs are those of the common Dart moth (Agrotis segetum), which was so extremely abundant last autumn. We would recommend the whole of the Strawberry plants to be carefully taken up and the roots examined, the bed itself thoroughly dug, and the grubs picked out by hand, which would be easy enough from the grub being so large and conspicuous. The ground should then be well dressed with lime water and soot.—W.

GEOMETRIC BEDS (*O. Barton*).—We have no doubt that your geometric composite bed will look very nice. We agree with you that you have not a bit too much scarlet. The scarlet, yellow, white, and purple, will make an excellent blending, and your bed is just large enough to give them effect. Such a large bed so divided will look best when looked down upon and seen all at once. If so viewed we do not see much advantage in raising the bed from the outside to the centre; nor do we see much advantage in the raised basket in the centre, unless that is high enough, and an open space below to see right through it over the rest of the bed. These are minor matters, however, of which those on the spot can judge best. Our friend Mr. Robson was, we believe, the first to attempt this plan of planting on a large scale. His lines and subdivisions are generally more artistic than geometric. The only objection to the general use of such beds is the difficulty of getting to the plants nearest the centre when the bed becomes one mass. Their great interest consists in the presenting such a mass of contrasted colour, like a carpet, to the eye.

TREATMENT OF VINE CUTTINGS (*J. A. J.*).—From the time that young Vines begin to root and grow they will enjoy a bottom heat of from 75° to 80°, until the roots fill the last pot you give them, and the wood begins to ripen. To thoroughly ripen that wood when it is desired to fruit the young plants next season, the bottom heat should be continued until the leaves begin to turn yellow, when the Vines may be lifted out of the bed for a week, then moved to an open vinery, or a wall facing the south, so as to get well hardened by the sun and air, whilst only as much water is given as will prevent what is green of the leaves flagging. When the leaves turn yellow the pots may be packed on the north side of a fence, and kept cool and dryish there before you wish to start them again, which is best done by giving them a temperature of from 45° to 50° for a fortnight, and then, if convenient, giving them a bottom heat of 60°, increasing it gradually to 75°, and a few degrees more after the buds are breaking. To obtain nice plants for planting merely bottom heat is not absolutely necessary, but you will get much better plants if you can give them a little bottom heat until they are established in eight-inch pots. To insert buds, say on the first day of the year, and gather Grapes from the plants thus formed, say in sixteen or seventeen months from the inserting of the bud, then the bud should at once receive a bottom heat of 60°, and have it increased gradually in a month to 75° and 80°, the top temperature ranging from 65° at night to 85° during the day from sun heat; and if such plants can have bottom heat until they are well established in 12 or 13-inch pots, the sooner will the wood be ripened, and the sooner will the plants be fit for being rested, before again exciting them into growth.

STRAWBERRY FORCING—EPIPHYLLUMS.—The queries of "A READER" on Strawberry forcing; and those of "EPI" who wishes to have a detailed account of the culture of Epiphyllums, will shortly be answered.

DRACENA NOBILIS (*A Young Gardener*).—It is evident the plant is in very bad health, and you only accelerated the evil by potting it and cutting it down. Your only plan now is, to plunge the pot in a mild hotbed, so as to promote root-action, and keep it there until fresh growths are made. The moist close air of a fernery is not suitable for it, though it would do fairly there in winter; but a vinery would be a better place for it in summer. It is rather a free grower, and requires a stove temperature to grow it well; but you grow it fairly by keeping it in the fernery in winter, and vinery in summer, only do not keep too wet. A cool vinery is too cold, and a shaded fernery unsuitable for it. Your soil is suitable.

PLANTING VINES (*Delta*).—Decidedly let well alone. There could be no harm in having a few Vines against the back wall, however, but these will not bear against the back wall after the Vines, 3½ feet apart, cover the length of the rafter. They will bear at the top where they have light. The thick planting is chiefly useful for getting a house soon filled and soon in fruit. The early fruiting may then be cut away to make way for the permanent ones.

SQUARE FLOWER-POTS.—"Y. Z." wishes to know where these can be purchased.

MELON FRAME (*W. B. M.*).—A frame 11 feet long by 6 wide, is quite large enough to grow Melons. They can give no opinion as to price, it so varies with quality of materials and other circumstances.

**WORMS IN HYACINTH POTS (*Hyacinthus*).**—Lime water will expel them and will not injure the Hyacinths.

**VINES FOR COLD VINERY (*T. W. U. R.*).**—Six Vines for a vinery where little artificial heat is given may be two Black Hamburgs, two Black Prince, and two Lady Downes'. *Tacsonia mollissima* will do as a climber for your greenhouse.

**PEAS—BEANS (*Young Amateur*).**—Tall Mammoth is the largest Pea. Dwarf Mammoth (Hair's), is also large. The two best early dwarfs are Tom Thumb and Bishop's Dwarf. The best early Peas to succeed each other, are Sangster's No. 1 and Dickson's Favourite. For second crop, Harrison's Perfection and Ringwood Marrow are very good. After these follow with Veitch's Perfection, Ne Plus Ultra, Knight's Marrows, Woodford's Green Marrow, Champion of England; and for late sowing in July and August, use the early kinds. Of Beans, Mazagan and Johnson's Wonderful. For the best Cinerarias you had better be guided by some of the celebrated growers. Berkeley's "Handbook of British Mosses" will suit you.

**SUCCESSION OF FRUITS (*A Constant Reader*).**—*Apples*.—Dessert: Devonshire Quarrenden, Joanneting, Kerry Pippin, Blenheim Pippin, Cox's Orange Pippin, Margil, Ribston Pippin, Ashmead's Kernel, Braddick's Nonpareil, Cockle Pippin, Cornish Gillyflower, Nonpareil, Sturmer Pippin, Wyken Pippin. Kitchen: Keswick Codlin, Cellini, Golden Noble, Hawthornden, Alfriston, Dumelow's Seedling, Northern Greening, Royal Russet, Winter Pearmain. *Pears*.—Autumn Bergamot, Bishop's Tomb, Hesse, Jargonelle, Louise Bonne of Jersey, Swan's Egg, Williams's Bon Chretien. Winter Nells. *Stewings*: Catillac. *Plums*.—July Green Gage, Perdrigon Violet Hatif, Green Gage, Purple Gage, Jefferson, Coe's Golden Drop. Preserving: White Magnum Bonum, Washington, Damson.

**CURRENTS (*G. D., of H.*).**—Any respectable nurseryman can supply the Red Cherry and Red Grape varieties.

**MELONS FAILING (*A Cottager in the Country*).**—The probable cause of failure was not watering the plants sufficiently, they only being watered four times, which would have been only a proper allowance for a fortnight of fine weather. The soil should have been kept moist, and, unless destroyed by disease, they would have survived the ripening of the fruit. The indifferent setting was probably due to an insufficiency of heat and air, and the not properly thinning the shoots, so as to admit light and air, and thus secure the maturation of the parts destined for bearing.

**HEATHS NOT FLOWERING (*J. M., an Amateur*).**—We do not know any difference in the mode of culture that can possibly affect the flowering, if proper treatment is pursued. We have seen as fine Heaths grown at Edinburgh, and as well bloomed, as in England. To grow Heaths well they require a house to themselves, and then, under ordinary treatment, they are the freest-blooming of plants. They require abundance of light, and air blowing on them almost constantly, and we think the indifferent blooming of your plants is caused by the want of these. Keep them cool, well aired, and in a light structure near the glass, and your plants cannot fail to bloom well. If you put them out at all in summer they should have the protection of a cold frame, so that the roots may not be dried up in consequence of the sun heating the pots, and also to protect them from heavy rains, admitting air all the same constantly. Charcoal, in small pieces about the size of a hazel nut, may be mixed with the soil, and it is desirable in soils that are at all close; turfy peat, well sprinkled or intermixed naturally with fine siliceous sand, is the most suitable compost.

**CALCULIARIES UNDER A NORTH WALL (*Juvenis*).**—Allow the cuttings to remain where they are until the last week in March, or beginning of April, by which time they will be well rooted, and may more safely be transplanted to a sunnier situation. We have about two thousand in two small frames, only occupying an area of 25 square feet each, and they are in a situation where they do not receive any sun whatever. We shall take out the points of the shoots early in March, and put them out in Celery trenches or turf-pits in a sunny situation in April, and then lift them with balls to their blooming quarters in May. Whilst in the trenches or pits we merely cover with any spare old lights, with further protection in case of frost; and by this simple process we turn out thousands of fine bushy plants instead of dozens of those pampered in pots. We do not care how small we can keep them over the winter. You may, however, remove them now, but it is only giving yourself needless trouble.

**NAMES OF FERNS (*A Young Gardener*).**—1, *Pteris aquilina*; 2, *Asplenium Fabianum*; 3, *Cheilanthes hirta*; 4, *Lustrea Sieboldii*; 5, *Pilea serpyllifolia*; 6, *Pteris hastata*; 7, *Litobrochia palmaria*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### PRICE OF NEW-LAID EGGS—PROFITS OF POULTRY-KEEPING.

I KNOW not whether your correspondent "C. S. J." resides in London or the country; but judging from the price he quotes for new-laid eggs at this time of the year—viz., 1s. 4d. per dozen, I presume the latter. The price of new-laid eggs, like everything else, is necessarily regulated by the demand, and I doubt not that what he states is quite correct as to some localities. In London, and particularly at the West End, genuine new-laid eggs are sold retail at 4s. and even 6s. per dozen from November to February. It is true that most dairymen and cheesemongers profess to sell new-laid eggs at as low a price as 1s. 6d. per dozen; but put it to their conscience about being really new-laid, and they will tell you that they are country eggs, and that they purchase them from the dealer as new-laid. Now, I have bought many such new-laid eggs, and found them without exception many weeks old, unfit for hatching and the breakfast-table—in fact, they are eggs picked for their size and appearance,

and probably imported from the continent. Were the public able to depend on getting really new-laid eggs during the winter months in London, 2s. 6d. per dozen would never be grudged, particularly for invalids and ship-passengers.

The preservation of eggs according to my system, published in your valuable Journal, is about to be carried out by an eminent firm; and I doubt not that in a few years we shall be able to purchase by those means well-authenticated fresh eggs at comparatively low prices at all times of the year.

In conclusion, I agree with you that your readers should form their own opinion on my balance-sheet of profit and loss in poultry-keeping, and not accept the figures as implicit facts under all circumstances.—GEO. K. GEYELIN, C.E.

### BRAHMA POOTRAS.

WE—that is, the Brahma lovers, are gradually building our pedestal; and when we have done, we will put our best specimen on the top, and he shall crow, "Victory."

I can corroborate Mr. Leworthy's statement of an old Indian recognising the Brahma as an Indian bird. I was recently showing my fowls to a gentleman of the civil service, home on sick leave. He is an ardent lover of natural history in all its branches, and was making inquiries as to the habits and merits of the different breeds, when he came to the Brahma. "I need ask nothing about them," he said, "I kept them in India for years."—F. F.

[Very likely, but that does not prove that they are not a variety of the Cochin-China. Let the pedestal be large enough for a specimen of each.]

HAVING said my say, I had intended to be silent, and certainly on reading Mr. Leworthy's few lines, I thought I, in common with other Brahma upholders, had got all that we could desire—viz., that at Burmah there was a breed of fowl that tallied with our Brahma. I crowed with delight; for I know Mr. Leworthy to be no mean judge of Brahmas, and he has very good ones; and I thought his few lines conclusive. I saw "Our Editors" note at the end, and in anticipation read their delight that the question was so satisfactorily settled, and that henceforth they intended to consider Brahmas as pure a breed as any other sort of fowl. What was my surprise to find they considered Mr. L.'s note conclusive that they were only a "variety of Cochin!" This, I am quite certain, was not the intention that prompted Mr. L. to write, and with the most humble deference to "Our Editors," I submit the reasoning is most false. Shanghai and Ava are upwards of 1000 miles apart, and if this reasoning is correct, any person writing in Shanghai of our island breeds—Game and Dorking, might with far more justice consider them only varieties of the same breed; for the distance between the extreme limits bears but a small proportion to the distance between Ava and Shanghai.

If there can be two distinct breeds of English origin, surely there may be two distinct breeds between Ava and Shanghai.—Y. B. A. Z.

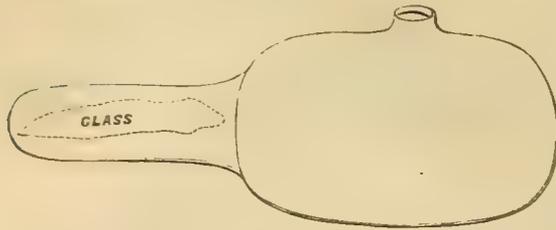

[With due submission, the above is all special pleading. Burmah and China join; but it now appears that Mr. Tanner saw the birds about 300 miles from Calcutta—but all this is of little import. Buff and White "Brahmin Fowls" were there; and no one could detect a specific difference between a Buff Brahma Pootra and a Buff Cochin China. We now must take our leave of the subject, rejoicing that it matters little that Brahmas are a variety of Cochin Chinas, since they are found to be worthy of patronage.]

### SEX OF EGGS.

ANY light that can be thrown on this subject is very desirable. "F. H." is told that eggs first laid will produce a majority of pullets, and those last laid a majority of cockerels. My experience teaches me exactly the contrary. Last spring I paid much attention to this point. I found that eggs laid in January and February produced three cockerels to one pullet; March and April three to two; May about equal numbers; June and July the eggs produced a large

majority of pullets. I think that the above figures will not differ materially from those of others who have kept a careful account of the sex of their chickens.—C. S. J.

#### GLASS IN A FOWL'S GIZZARD.

I ENCLOSE a piece of glass nearly 2 inches long and a quarter of an inch square, which I extracted from the gizzard of a Spanish hen sixteen months old, killed this week for the table. The glass must have been swallowed many months ago, as it is regularly ground, and it formed in the gizzard an excrescence in the shape of the annexed sketch. The hen appeared in good health, was in good condition, and a good layer. In my experience I never saw such a malformation of the gizzard, as the whole length of the glass which was projecting beyond the gizzard was covered with flesh  $2\frac{1}{2}$  inches in length and one-eighth of an inch in thickness. Perhaps some of your readers may have observed similar cases without prejudicial effects on the health or functions of the hen.—G. K. GEYELIN.

#### PARIS POULTRY SHOW.

EVERY one will thank you for your notice of the Paris Show. It is calculated to do much good, and to stir up our supine English public as to the merits of the poultry question. We hope there will be an alteration in the competition next year, and that it will be thrown entirely open. Application was made by one of our principal poulterers to the Minister of Agriculture, but he was told the entries were confined to France. We believe the good respectable old Dorkings would have held their own. They will again next year offer to tilt with blunted weapons against all comers.—B.

#### SEX OF EGGS—COLOUR OF AYLESBURY DUCKS' BILLS.

I BELIEVE it is well known to ornithologists, that of the Finches, which have two nests in one season, the first contains all cocks, and the second all hens. This would lead us to expect a contrary result to that which your correspondent "F. H." speaks of. However, I for one will take notice of the sex of chickens from eggs laid at various times by the same hen, and let him know the result at the end of the season.

For the comfort of your correspondent, "G. B. H." allow me to say that the light-coloured bill of the Aylesbury Duck is not confined to the neighbourhood of Aylesbury. I, too, have bought Ducks of Mrs. Seamons, and also of a well-known breeder near Grantham, which have not changed the colour of their bills, although I have taken no pains to keep them out of the sun, or to let them out only on frosty mornings, a common recipe for preserving the delicate colour. I have also bred birds from this stock, with light bills. Now on the land where my Ducks are bred, I can answer for neither chalk nor sand being found, nor indeed clay, except at a depth ten times the length of a Duck's bill. I also know of a farmyard in Norfolk, where for several years past some Ducks have been bred with bills the colour of an orange, and others nearly, if not quite, as pale as those of the prize Ducks at Birmingham. Chalk and sand are very abundant there, but that only serves to increase the difficulty. However, I quite agree with "G. B. H." in wishing for the orange bill to be admitted into our prize pens, partly

for the reasons he gives, and partly on account of the beautiful contrast it makes with the white plumage of the Aylesbury Duck.—C. H. L., *Rectory, Edith Weston.*

#### POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.

(Continued from page 57.)

##### FOOD FOR POULTRY.

WHEN poultry is kept confined its food must be appropriate. A fowl kept in a free state on a farm, can with advantage be fed all the year round with barley or oats only, as she will supplement her meals with animal and vegetable matters of her own finding; therefore, an equivalent should be given to penned-up poultry; but, again, as they have not so much bodily exercise as when in a free state, their digestive powers are weakened, consequently they are subject to inflammation of the bowels when fed on whole grain only. After this explanation my readers will understand the reason why I advocate all grain to be ground, and the meat and green vegetables to be minced; but, apart from the sanitary consideration, it becomes an important economical fact in a large breeding establishment, as it is well known that food made of grain and which requires little exertion of the digestive organs, has far greater feeding and fattening qualities than whole grain.

There is another point connected with feeding to which I wish to allude. The diet should be varied almost daily; but green vegetables finely minced ought to form part of every meal, and occasionally some oxide of iron, and at other times flowers of sulphur, mixed with the food will greatly tend to keep poultry in good health.

##### FOOD FOR YOUNG CHICKENS.

Indian corn and barleymeal, boiled rice, mashed potatoes, bread crumbs, &c., steeped in milk and water—any of the above separately or mixed together will do well. Finely-chopped green vegetables should be given daily, and occasionally hard-boiled eggs chopped fine, and a supply from the vermin nursery. Fine gravel should be put in the inner saucer shown in fig. 18.

Water should be supplied between the two saucers to prevent the chickens wetting themselves, and it should be renewed daily. Clean water and a plentiful supply of food given about four times a-day, combined with the comfort of the artificial mother, will keep the chickens in better condition than when left to roam in search of food.

##### FOOD FOR THE BREEDING AND LAYING STOCK

May consist of a mixture of the various cereals coarsely ground and made into a stiff paste. This food should be put in the feeding-fountains, figs. 3 and 4, where it cannot be wasted or dirtied. Occasionally in fine weather whole grain can be thrown broadcast in the open run. The other food should be finely-chopped vegetables, such as the waste of the kitchen garden, mangold wurtzel, swedes, &c., in a green state, mashed boiled potatoes and rice, minced boiled meat mixed into a paste with the liquor from the meat, and seasoned with salt and pepper. Finely-powdered oyster shells or a little chalk forms a genial condiment. Powdered charcoal, oxide of iron, and flowers of sulphur alternately, and at given intervals mixed with their food will keep them in perfect health. The best feeding-time is at sunrise, and about two hours before roosting-time.

##### FOOD FOR THE FATTENING STOCK.

As they are still more closely confined they require a diet of a highly fattening nature and of easy digestion. When once poultry is penned up for fattening, the diet ought not to be varied. There are three different ways adopted in fattening poultry.

1st. Free feeding, consisting in supplying a fowl with food and water *ad libitum*. This takes a much longer time, is more expensive, and less satisfactory as regards the flesh. In this mode four or six fowls are best penned up together, as they will feed more freely than in solitary confinement.

2nd. Forced dry feeding, consisting in cramming the fowl with pills made of suitable food twice or thrice a-day, and giving water *ad libitum*.

3rd. Forced liquid feeding consists in reducing the food

to a liquid state with milk and water, and then pouring it down the gullet by means of a funnel three times a-day, and not supplying the fowl with any water.

PREPARATION OF THE FATTENING FOOD.

Barleymeal, or mixed in equal quantity with Indian corn-meal, should be made into a thick paste with milk and water and seasoned with bay salt. This paste is then either made liquid for liquid feeding, or into pills, which should be dipped in milk and water before they are given to facilitate their being swallowed.

Experiments have proved that seasoning poultry food with bay salt has the following advantages:—

1. To render the fattening of shorter duration.
2. To produce with the same quantity of food more flesh and fat.
3. To give the flesh greater firmness and flavour, and to render the fat more compact and of a finer grain.

Molasses or sugar mixed with the meal has also good fattening properties.

IMPROVED FATTENING PENS.

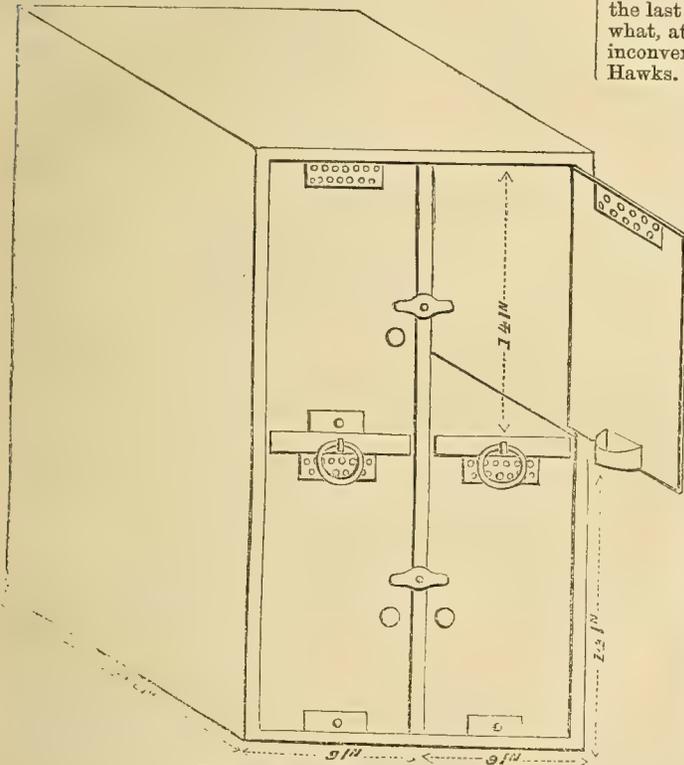

Fig. 22.—Improved Fattening Pens.

These fattening pens are so constructed that they can be placed in the open air, forming a building of themselves. Each fowl has her own compartment, and is thus in solitary confinement, and being unable to see other fowls, fattening is considerably hastened. The floors of the cells should be drawn out daily and cleaned and whitewashed, then returned with the dry underside uppermost and sprinkled with some sand. The cells should also be whitewashed for every fresh occupier. The doors are solid boards with a piece of perforated zinc for ventilation at the top, and a drinking-cup at the bottom. These pens combine all the sanitary advantages for the speedy fattening of fowls.—G. K. GEYELIN, Civil Engineer, London.

(To be continued.)

MEGRIMS IN PIGEONS.

I SHOULD be greatly obliged by being informed of any cure for what is called here the megrims in Pigeons, as mine have been much troubled with it lately, and some very

good birds have died in consequence. The birds at first mope about, eat little, and in a day or two begin shaking their heads and twisting them about, sometimes falling forwards. They continue so for a day or two and then die, neither eating nor drinking all the time.

I keep the birds in a good warm cote facing the south. Some have their liberty and others have a covered pen 7 yards by 3, shielded by a house on the north, and latticed in front. I feed them on grey peas, Indian corn, lentels, or wheat, or sometimes old beans, generally three kinds at once. The birds flying as well as those kept in, both young and old, have had it.—AIREDALE.

[I am unable to inform "AIREDALE" of a cure for his Pigeons, but it seems to be apoplexy. If any of mine were so affected, I should try pills containing one grain of calomel and pull out their tails.—B. P. B.]

HAWKS AND PIGEONS.

I HAVE studied your poultry department very closely for the last year to see if there was anything mentioned about what, at least in this country, is considered the worst of the inconveniences to which Pigeon fanciers are subjected—i. e., Hawks. I am led to believe, therefore, either that those birds are not very numerous in England, or that English Pigeon fanciers know some effectual remedy against the scourge, allowing them at the same time to give the Pigeons their liberty all the year round. I am compelled to have my Pigeons locked up from September to May, and during this long arrest they afford me very little amusement indeed, although my loft is roomy enough; and generally some good birds die-off during the captivity, and others are lost during the first days of liberty in spring.—B., Gothenburg, Sweden.

[I am sorry to say we know of no means of preventing the Falcons from taking our Pigeons; but fortunately for English Pigeon fanciers these rapacious birds are not very numerous in England, as gamekeepers have almost exterminated the race, and the smaller Hawks rarely attempt to catch Pigeons. Many years back when residing at Dover, the Peregrines that lived about the chalk cliffs used to make sad havoc among my high-flying Tumblers, but they did not descend into the town to take those that did not fly high. Some quick-flying Pigeons are not easily caught by these birds, and if they have the shelter of a town to drop into generally escape, as the Falcon is shy of following among the houses. Mr. Ackermann, the Pigeon dealer in Coblenz, on the Rhine, who kept a large flight of the Feather-footed Tumblers, told me he used to keep a few pairs of active little Hollanders, which he turned out when he saw the bird of prey approach, and as these would soar up and attract the Hawk, he

could get his heavier birds down and out of harm's way. The little Dutch Tumblers generally saved themselves by their activity, and if hard pressed would drop among the houses where the enemy did not like to follow, unless very hard pressed by hunger.—B. P. BRENT.]

JEDBURGH POULTRY SHOW.

It gives us great pleasure to announce that the entries for the above Exhibition (held on the 18th and 19th inst.), have this year increased in number, and that the quality of the poultry shown has evinced a remarkable improvement also. A reference to the appended prize list will at once convince our readers that the Jedburgh Show this year was well supported by most of the principal breeders in the kingdom. It is certain that no committee of a poultry show can strive more heartily than do the governing body of the Jedburgh meeting to secure public interest and support, each member being as indefatigable as though the whole chance of success depended exclusively on his own individual exertions. Every member of the Committee is constantly

at his post, and all things are carried out with perfect fairness, courtesy, and liberality. As in most public matters, however, there is a weak point where improved arrangements would greatly tend to enhance success, and give increased satisfaction in the sequel to all parties concerned. It is simply this. Independent altogether of the vastly improved quality of the poultry, as compared with former years, now consigned for exhibition to the Jedburgh Committee, the number of pens (491), is considerably too large for the time under the present rule allotted to the purposes of arbitration. It was not until after two o'clock in the afternoon that the birds were all penned and ready for the arbitrations, and at this season of the year night-fall closes within but very little more than a couple of hours of that time; after which dim twilight or lighted candles form but an uncertain substitute at best for the purpose of judging correctly, particularly as all birds themselves are timid and distrustful on the application of artificial light. However practically experienced the parties officiating as arbitrators may be, we are fully assured that their onerous duties would be far more speedily completed by daylight, and with less difficulty to all concerned. It is, we are told, to wait the arrival of the midday train this delay arises, and fears are expressed that the number of entries would be materially lessened were a different plan adopted. Our own experience, however, proves that, however great the latitude allowed for the arrival of the birds, there will always be some laggard dilatory individuals trespassing beyond the regulations. In proof, even in the present case, we find in the Jedburgh printed catalogue, at page 16, the following verbatim announcement:—"Pens 55, 231, 243, 296, and 303 arrived too late for competition, at 6.30, P.M." We can quite understand the really earnest desire of the Committee, as displayed, to give the greatest possible amount of accommodation to all parties concerned, even at the expense of personal trouble to themselves; but we are, nevertheless, assured that the great majority of exhibitors would hail with unfeigned delight a re-arrangement of rules by which all awards should be completed by daylight; and the imposition of a rule, strictly adhered to, enforcing the arrival of the specimens the previous evening would obviate all objections, without materially lessening the competition.

We now proceed to a few brief remarks on the Show itself. It is but rarely we meet with so good a display of *Spanish* fowls as were exhibited at Jedburgh, the veteran exhibitor Mr. Teebay, of Preston, taking the silver cup in a competition that would have enhanced the credit of our largest public meetings. In *Grey Dorkings* the classes were very good; but we were sorry to see so many excellent birds of otherwise remarkably fine development suffering from that bane of Dorking fowls, deformed feet. It is well to remind our readers, this disease is almost universally first produced from placing the perches too high from the ground, and it should be always remembered that toes so injured are afterwards rarely curable. There was a grand display of both Buff and Partridge-coloured *Cochins*, and some unusually good White ones. The *Game* fowls were really good, but the classes were less numerous filed than we anticipated, so much so that in one class, the Extra variety of *Game*, there were but two competitors, and no prizes were awarded, as, by rule of the prize schedule, a competition of three pens was necessary. A pen of *Black Game* exhibited in this class were most praiseworthy. The *Hamburgs* were, as expected, first-rate, and the *Polands* were equally good. A sweepstakes for *Bantams* brought a capital competition of forty-two pens, with scarcely a second-rate lot among them; and the *Selling Class* for both poultry and Pigeons was a thoroughly successful one, and produced many claimants.

As regards the *Pigeons*, Jedburgh has reason to boast of as good a collection as we could ever wish to meet with at any show, each class being numerously and well filled with specimens which the closest scrutiny only tended to improve. The pens for these public favourites were, however, placed too high from the ground for ladies and "little folks" to reap much pleasure from inspection, which we regard as rather a drawback to this most interesting portion of the meeting, though the elevation at which they were placed we believe to be quite unavoidable.

A show of *Canaries* and other *Song Birds* concluded the

routine of this excellent meeting, and proved a very enjoyable portion of the Exhibition.

The most anxious care was given by the Committee to every specimen entrusted to them, and, consequently, every bird seemed unusually quiet and comfortable. It is this line of management that invariably insures success. The Jedburgh Show increases annually, and will rank among the principal poultry exhibitions of North Britain.

**SPANISH.**—Cup, R. Teebay, Fulwood, near Preston. Second, F. R. Pease, Darlington. Third, J. Shorthose, Newcastle. Commended, J. Biggar, Ecclefechan. *Chickens.*—First, W. Meff, Aberdeen. Second, R. Teebay. Third, J. Shorthose. Commended, J. Biggar; G. Taylor, Inverury; H. Crawford, Beith.

**DORKING (Coloured).**—Cup, F. R. Pease, Darlington. Second, W. Bonthron, jun., Kirkealdy. Third, W. Amos, Ilfe. Highly Commended, Lord Binning, Kelse. Commended, Countess de Flahault, Kincardine-on-Forth; Mrs. Dickens, Coldstream; John Curror, Edinburgh. *Chickens.*—First, J. Anderson, Meigle. Second, J. Jardine, Ewes. Third, Miss Milne, Kelse. Highly Commended, J. Carror. Commended, Mrs. Dickens; Lord Binning; J. Stocks, Kirkealdy; Rev. M. H. Graham, Kelse. *Pullets.*—First, W. Cheyne, Selkirk. Second, J. Anderson. Third, F. R. Pease, Darlington. Highly Commended, Mrs. Elliot, Jedburgh; Miss Milne; E. Kerse, Jedburgh. Commended, T. L. Jackson, Dumfries; Lord Binning.

**COCHIN-CHINA (Any variety).**—First, J. Shorthose, Newcastle. Second, J. Poole, Ulverstone (Buff). Third, J. Biggar, Ecclefechan (White). Commended, W. Arras, Ormiston Mains, Roxburghshire. *Chickens.*—First and Third, J. Poole (Buff and Dark). Second, Miss Milne, Kelse.

**BRAHMA POOTRA.**—First, Miss H. Scott, Jedburgh. Second, E. Kerse, Mounteviot. Third, Miss Roy, Kelse. Highly Commended, Mrs. H. Barclay, Perth. Commended, F. R. Pease, Darlington; J. Shorthose, Newcastle.

**GAME (Black or Brown Reds).**—Cup, H. M. Julian, Hull. Second, Lord Binning. Third, H. Beldon, Gilstead. Highly Commended, J. Smith, Grantham; W. Boyes, Beverley. Disqualified (hen short), J. Fletcher, Stancleugh, Manchester.

**GAME (Duckwing).**—First, J. Patterson, Kelse. Second, H. Beldon, Gilstead. Third, J. Gibson, Dalkeith. Highly Commended, J. Anderson, Meigle. Commended, A. M. Macculloch, Barhead.

**GAME (Any variety).**—*Chickens.*—First, J. Smith, Grantham (Duckwing). Second, J. M. Grainger, Whitwell, Yorkshire (Brown Red). Third, R. Pickering, Carlisle (Black Red). Commended, H. M. Julian, Hull; J. Anderson, Meigle; H. Beldon, Gilstead.

**HAMBURGH (Silver-spangled).**—First and Second, H. Beldon, Gilstead. Third, Mrs. Craw, Jedburgh. Commended, J. U. Somner, Jedburgh.

**HAMBURGH (Silver-pencilled).**—First and Second, H. Beldon. Third, J. Platt, Dean, near Bolton.

**HAMBURGH (Golden-spangled).**—First, H. Beldon, Gilstead. Second, W. K. Duxbury, Leeds. Third, A. Hatley, Selkirk. Highly Commended, J. Muirhead, Haddington; A. Copland, Aberdeen. Commended, C. Anderson, Nenthorn; R. Dickson, Selkirk.

**HAMBURGH (Golden-pencilled).**—First, W. Cheyne, Selkirk. Second, H. Beldon. Third, J. M. Innes, Paisley. Commended, H. Beldon.

**BANTAMS (Game).**—First, D. Broomfield, Kelse. Second and Third, Miss E. A. Aillonby, Grasmere. Highly Commended, W. Mabon, jun., Jedburgh. Commended, Mrs. Craw, Jedburgh; F. R. Pease, Darlington; W. J. Routledge, Aberdeen.

**BANTAMS (Any other variety).**—First, F. R. Pease, Darlington. Second, Countess de Flahault (Japanese). Third, H. Beldon (Black). Highly Commended, J. Anderson, Meigle; F. R. Pease, Darlington; F. L. Roy, Nenthorn (Silver-laced Sebright).

**GRESE (Grey and Mottled or White).**—First, S. Swan, Bush. Second, F. R. Pease, Darlington. Third, Mrs. Elliot, Hyndhope. Highly Commended, T. E. Boog, Tynhouse. Commended, Mrs. Craw, Jedburgh.

**DUCKS (White Aylesbury).**—First and Second, J. Smith, Grantham. Third, J. A. S. E. Fair, Gillistongues. Highly Commended, S. Swan; H. Beldon. Commended, Lord Binning; W. Hood, Jedburgh; J. A. S. E. Fair.

**DUCKS (Rouen).**—First, W. Hood. Second, Mrs. Elliot, Hyndhope. Third, J. Menzies, Kincardine-on-Forth. Commended, J. Paterson, Kelse.

**DUCKS (Any other Distinct Breed).**—First, J. Jennison, Manchester (Carolina). Second, T. Elliot, Hyndhope (Wild). Third, J. R. Jessop, Hull (East Indian). Highly Commended, H. Beldon, Gilstead; J. Jennison (Wilgeons). Commended, Countess de Flahault (Black East Indian).

**TURKEYS (Any variety).**—First, J. Smith, Grantham (Cambridge). Second and Third, F. R. Pease, Darlington. *Pouls.*—First and Third, J. Smith (Cambridge). Second, F. R. Pease. Highly Commended, T. C. Harrison, Hull (Cambridge); F. R. Pease.

**ANY OTHER VARIETY.**—First and Second, H. Beldon (Polands). Third, J. A. S. E. Fair, Gillistongues (White Dorkings). Highly Commended, J. R. Jessop, Hull (Black Polish); F. R. Pease (Polish); J. A. S. E. Fair (White Dorkings); Countess de Flahault (Black Polands); W. K. Duxbury, Leeds (Black Hamburgs).

**SINGLE COCK—Spanish.**—First, J. Shorthose, Newcastle-on-Tyne. Second, E. Brown, Sheffield. Third, H. Beldon. Highly Commended, J. Biggar, Ecclefechan. Commended, J. Lunn, Jedburgh. *Dorking.*—First, Countess de Flahault. Second, Mrs. Elliot, Hyndhope. Third, J. Menzies, Kincardine-on-Forth. Highly Commended, G. Louglae, Hyndhope. Commended, J. A. S. E. Fair; T. Y. Craig, Galloway. *Cochin-China.*—First, B. J. Charters, Kelse. Second, T. Y. Craig. Third, J. Shorthose. Highly Commended, Mrs. Dickens, Coldstream. *Game (Any variety).*—First, J. Smith, Grantham. Second, W. Easton, Jedburgh. Third, J. M. Grainger, Whitwell, Yorkshire. Commended, Miss Milne, Kelse; J. Anderson, Meigle.

*Hamburg (Any variety).*—First, H. Beldon. Second, C. A. Lockhart, Kirkealdy (Golden-pencilled). Third, H. Beldon. Highly Commended, Mrs. Craw, Jedburgh; F. L. Roy, Nenthorn (Silver-spangled); C. M. Royd, Greenhill. Commended, Mrs. Craw; Miss H. Scott (Golden-spangled); F. L. Roy (Silver-spangled); Mrs. Blackie, Jedburgh (Silver-spangled).

The **SILVER CUP**, given to the most successful Exhibitor in the preceding Class, was gained by H. Beldon, Gilstead.

**SWEEPSTAKES FOR BANTAMS.**—First, G. J. Harvey, Jedburgh (Duckwing). Second, F. R. Pease, Darlington (Cochin Bantams). Third, Miss Huggan, Jedburgh (Black Red Game). Highly Commended, W. Mabon, jun., Jed-

burgh; W. Dixon, Sunderland; D. Robertson, Beverley (Game); F. L. Roy, Nenthorp (Black Game); E. Brown, Sheffield; A. Hunter, Jedburgh; T. Short, Glasgow. Commended, W. J. Routledge, Aberdeen (Game); F. L. Roy (Silver-laced); J. Turnbull, Jedburgh; R. Tate, Leeds.

**SELLING CLASS.**—First, G. Macmillan, Jedburgh (Manorkies). Second, T. L. Jackson, Dumfries (Silver-grey Dorkings). Third, W. K. Duxbury, Leeds (Hamburgs). Highly Commended, J. Poole, Ulverston (Cochin-China); G. Arbuthnot, jun., Mavisbank (Brahma Pootra); J. Barton, jun., Jedburgh (Black Red Game); J. Craw, Jedburgh (Hamburgs); J. R. Jessop, Hull (East Indian Ducks). Commended, C. A. Lockhart, Kirkcaldy (Cochin-China); Miss Roy, Nenthorp (Brahma Pootra); L. Malone, Northumberland (Game); W. Cheyne, Selkirk (Hamburgs); J. Craw (Hamburgs and Rouen Ducks); S. Swan, Bush (Aylesbury Ducks); J. A. S. E. Fair (Aylesbury Ducks); J. Anderson, Meigle.

**COTTAGERS' PRIZES.**—First, A. Henderson, Jedburgh (Dorkings). Second, W. Cooper, Helmsley, Yorkshire (Golden-spangled Hamburgs). Third, Miss M. Turnbull, Northumberland (Game). Commended, W. E. Millar, Selkirk (Turn Dorkings).

**PIGEONS.**

**TUMBLERS (Almond).**—First, J. R. Robinson, Sunderland. Second, M. Sanderson, Edinburgh. Third, J. Bell, Newcastle-on-Tyne. Highly Commended J. R. Robinson; E. Brown, Sheffield.

**TUMBLERS (Any other variety).**—First, R. Pickering, Carlisle. Second, J. Bell, Newcastle-on-Tyne (Kites). Third, J. R. Jessop, Hull. Highly Commended, H. Yardley, Birmingham. Commended, R. Thomson, Kendal.

**FANTAILS.**—First, J. R. Jessop, Hull. Second, H. Yardley, Birmingham. Third, W. Veitch, jun., Jedburgh.

**POWTERS.**—First and Second, M. Sanderson, Edinburgh. Third, E. Brown, Sheffield. Highly Commended, H. Yardley, Birmingham. Commended, R. Cleaver, Melrose; T. Little, Selkirk; J. R. Robinson, Sunderland.

**NUNS.**—First, R. Cleaver, Melrose. Second, H. Yardley. Third, A. Good-fellow, jun., Jedburgh. Highly Commended, W. Veitch, jun., Jedburgh.

**OWLS.**—First and Second, H. Yardley. Third, W. Johnston, Carlisle. Highly Commended, J. Bell, Newcastle-on-Tyne. Commended, G. Byres, Northumberland; W. Veitch, jun., Jedburgh; T. Short, Glasgow. Disqualified, J. R. Robinson, Sunderland.

**TURBITS.**—First, Mrs. Craw, Jedburgh. Second, J. W. A. Collier, Jedburgh. Third, H. Yardley. Highly Commended, G. Byres, Northumberland; T. Short, Glasgow.

**JACOBS.**—First and Second, W. Veitch, jun., Jedburgh. Third, Mrs. Craw, Jedburgh. Highly Commended, R. Pickering, Carlisle.

The **SILVER CUP**, given to the most successful Exhibitor in the preceding Pigeon Classes, was gained by H. Yardley, Birmingham.

**ANY OTHER VARIETY.**—First and Third, H. Yardley (Satinettes and Carriers). Second, M. Sanderson, Edinburgh (Barbs). Highly Commended, R. Cleaver, Melrose (Blue Dragons); J. Muirhead, Haddington (Priests); J. R. Jessop, Hull (Barbs); Mrs. Craw, Jedburgh (White Barbs); Countess de Finsault (Roman); H. Yardley (Runts); T. Short, Short, Glasgow (Magpies). Commended, J. R. Robinson, Sunderland (Trumpeters); J. Sharp, Johnstone, Renfrewshire (Blue Brunswicks); Mrs. Craw (Yellow Barbs).

**SELLING CLASS (Any Variety).**—First and Third, J. E. Jessop, Hull (Owls and Fantails); Second, R. Thomson, Kendal (Nuns). Highly Commended, T. Short, Glasgow (Fantails); R. Thomson (Spangled Swabians).

**CANARIES.**

**SCOTCH FANCY (Yellow).**—Cock.—First, R. Ballantyne, Hawick. Second, R. Swanston, Jedburgh. Very Highly Commended, T. Stoddart, Selkirk. Highly Commended, G. J. Harvey, Jedburgh. Commended, J. Hall, Jedburgh. Hen.—First, J. Kemp, Galashiels. Second, J. Grierson, Jedburgh.

**SCOTCH FANCY (Buff).**—Cock.—First, R. Swanston, Jedburgh. Second, J. Bannister, Galashiels. Highly Commended, J. R. Thomson, Hawick. Commended, A. Ferguson, Kelso; J. Hall, Jedburgh; J. Hardie, Galashiels. Hen.—First, J. R. Thomson. Second, W. Finlay, Jedburgh. Very Highly Commended and Highly Commended, R. Ballantyne, Hawick. Commended, G. J. Harvey, Jedburgh.

**BELGIAN FANCY (Yellow).**—Cock.—First, J. Barton, jun., Jedburgh. Second, W. Tinline, Galashiels. Very Highly Commended, W. Cheyne, Selkirk; J. Barton, jun. Hen.—First, W. Tinline. Second, J. Cleghorn. Very Highly Commended, J. Kemp, Galashiels.

**BELGIAN FANCY (Buff).**—Cock.—First, G. Laidlaw, Galashiels. Second, J. Barton, jun., Jedburgh. Very Highly Commended, T. Hope, Jedburgh. Commended, W. Cheyne, Selkirk; J. Barton, jun. Hen.—First, J. Kemp, Galashiels. Second, J. Marshall, Galashiels. Very Highly Commended, W. Tinline, Galashiels. Highly Commended, J. Barton, jun. Commended, J. Harvie, Galashiels.

**FLECKED (Yellow).**—Cock.—First, A. Ferguson, Kelso. Second, G. Laidlaw, Galashiels. Very Highly Commended, W. Finlay, Jedburgh; J. Barton, jun., Jedburgh. Highly Commended, W. Finlay; Mrs. Craw, Jedburgh; J. Swart, Galashiels. Hen.—First, W. Finlay. Second, G. Laidlaw. Highly Commended, T. Stoddart, Selkirk; Miss Ollier, Jedburgh. Commended, G. Laidlaw.

**FLECKED (Buff).**—Cock.—First, W. Swanston, Kelso. Second, Miss Collier, Jedburgh. Very Highly Commended, T. Stoddart, Selkirk. Highly Commended, W. Trotter, Hawick. Commended, J. Marshall, Galashiels; T. Hope, Jedburgh. Hen.—First, J. Kemp. Second, W. Swanston. Very Highly Commended, G. J. Harvey, Jedburgh. Highly Commended, T. Stoddart.

**MULE COCK.**—Second Prize, W. Johnstone, Carlisle.

The officiating Judges were—for Poultry and Pigeons, Edward Hewitt, Esq., Sparkbrook, Birmingham; and for Canaries and Song Birds, J. Broomfield, Esq., Edinburgh.

**BUENOS AYRES DUCKS AND VITALITY OF EGGS.**

HAVING observed last year in your Journal an inquiry respecting the vitality of eggs when sat upon, I noted with greater interest the points stated beneath, the truth of

which I can vouch for, though the statements may appear almost fabulous.

I had three Buenos Ayres Ducks and a drake. They began laying about the second week in January, and though they made nests in the hedge, I kept them in a large pen at night with a nest in it. The first three or four eggs these birds lay are quite black, they then become slate coloured, and afterwards a sort of grey. Two of the Ducks began sitting in the first week in April: the first Duck sat closely and well; the second sat well till about four o'clock each day, when she came off and seldom returned for hours. About the fifth day she left her eggs entirely and they were several times quite cold, but as I had three or four hens sitting at the time, I gave them to a Dorking pullet, not in the least expecting any good results, but chiefly as an experiment.

The Duck No. 2, then made a nest under a rick where she and No. 3 laid every day, till No. 2 again took to sitting, and the other Duck was removed that she might not lay in the nest. It is of this Duck I have the most extraordinary things to relate. She always came off her nest about five o'clock, would fly over the hedge or any distance to join the other, and remain off two or three hours at a time, once for four hours. I thought her sitting so useless, that at the end of three weeks I determined to destroy her nest and break all the eggs, which I commenced doing, when in the first I broke appeared a very fine healthy Duck; therefore, I desisted, thinking, perhaps, she might have one or two. Two days before the time of hatching I was passing by the rick, and to my surprise saw several little heads from under her, and on removing her to a safer spot we found, strange as it may appear, that she had hatched every egg and had a brood of twelve ducklings. The egg I had broken would have made thirteen. They were all strong healthy Ducks, and she reared them all and another brood during the year.

But to return to the first Duck, which sat splendidly. She hatched only seven, and the Dorking pullet ten. The third Duck sat in the hedge, coming off every evening about five o'clock, and remaining off one or two hours each time. She sat three times in the course of the summer, and had broods of ten and eleven each time. From all this it would appear, that the Duck being accustomed to seek its own food and to remain off for hours, the eggs are not injured like those of other fowls. I must say that my Rouen Ducks which sit well and seldom remain long off their nests, never had such large broods or did so well. It is still quite an enigma to me, as the Buenos Ayres is not nearly so careful in making or covering her nest with feathers when she leaves it as the Rouen Duck.—SHARPSBUR.

**MR. LANGSTROTH, THE AMERICAN APIARIAN.**

RESIDING some six hundred miles inland, I saw for the first time, during a recent visit to Philadelphia, a set of your Journal. In its apiarian department, to me, of course its first attraction, I was gratified to find that my labours in this field were known and appreciated, and for this my acknowledgments are especially due to Mr. Bevan Fox.

One of your ablest contributors, "THE DEVONSHIRE BEE-KEEPER," has, however, done me injustice, inadvertently, doubtless, in representing me as introducing the German frame-hive, with their mode of managing bees, into America.

Had I stood in the relation of a mere borrower from the German apiarians, I should have unhesitatingly said so, for nothing is more foreign to my nature than a wish to appropriate the labours of others, or to ignore their merits. From Aristotle and Columella, to Bevan and Dzierzon, I have taken nothing, knowingly, without proper acknowledgment.

Unacquainted with the German language, and having access to no foreign works on bee culture, Huber and Bevan excepted, I knew nothing even of the existence of Dzierzon and Berlepsch until after my hive was invented, and my apiarian practice adopted. As to the hive invented by the Baron Von Berlepsch, from which Mr. Woodbury supposes me to have copied mine, I would simply state that it was not given to the public until after mine had been largely and publicly used.

While claiming to have devised a system of bee culture substantially the same with that of Dzierzon, before I had any knowledge of his valuable labours, I have in all the editions of my work on "The Hive and Honey Bee," cheerfully acknowledged my obligations to him for much valuable information, more especially for the flood of light which by his discovery of parthenogenesis, he has thrown upon the whole physiology and management of the honey bee.

My appreciation of the merits of your Journal, and its extensive circulation among bee-keepers, must be my apology for requesting you to occupy so much of your space with matters personal to myself. It would afford me great pleasure to be numbered hereafter among the contributors to your apiarian department.—L. L. LANGSTROTH, *Oxford, Ohio.*

[We can at once answer for "A DEVONSHIRE BEE-KEEPER," that he will most readily correct any error he may have fallen into, and still more readily in the case of a brother apiarian so favourably known. We are more than pleased to include Mr. Langstroth among our list of contributors.—Eds.]

## A NEW CHAPTER IN THE NATURAL HISTORY OF THE BEE.

BEE COMMOTIONS AND QUEEN ENCASEMENTS.

(Continued from page 62.)

In accordance with the concluding paragraph in my last article, I shall now proceed to lay before the apiarian readers of this Journal my present views, as evolved from much experience of the curious phenomena, which I have designated Bee Commotions and Queen Encasements. It will be seen that during my investigations, my views varied with the varying character of the cases coming under my notice, and that I was compelled to abandon the adoption of any uniform rule or principle as applicable to a solution of all of them. I shall, perhaps, partly be anticipated, therefore, when I now state what these views are, and the conclusions at which I have ultimately arrived. I am of opinion—

1st. That queens may be encased or imprisoned by reason of the entrance of stranger bees into a hive.

2nd. That queens may be encased or imprisoned when superannuated and infirm through age, or from any natural defect in their procreative powers—such as exhausted fertility; and

3rd. That young queens may be encased or imprisoned when unfecundated beyond a certain age, and when in an abnormal condition.

I shall illustrate the proofs of each of these headings by one or two experiments selected out of many.

First, then, queens may be encased or imprisoned by reason of the entrance of stranger bees into a hive.

In my article entitled "Experimental Apiary" (peace to its memory!), it was not without reason, that among other things therein referred to, I emphatically condemned the shifting or transposition of hives. Many years ago, as an experiment, I transposed several hives all at one time in the spring, in order that weaker ones might be strengthened at the expense of the stronger. The result was queen encasements and massacres. If any one has never seen a queen encasement, he has nothing to do but to transpose a couple of hives, and in all likelihood he will witness this curious phenomenon in one of its simpler phases at least, and, perhaps, the death of a queen to boot.

But I had frequently suspected, as before hinted, that the entrance of stranger bees into a hive through whatever cause, often led to the encasement of the queen, and consequent commotion. Indeed, I could not account on any other principle for the phenomena exhibited in some of my hives. I shall narrate a case or two in point, which took place in my apiary no farther back than the month of August last.

It will be remembered that in the middle of that month the weather became intensely hot and oppressive. The thermometer marked more than an ordinary temperature and the consequence was, that the bees of most hives lay out in masses. On returning after a short absence from home, I regretted to find that the massive combs of a unicombe-hive sited in my bee-house, had collapsed and fallen down from

the heat, killing and crushing one-half of the entire population. I removed the unicombe, shut up the entrance, and allowed the surviving bees to find access into whichever hive they choose. They entered an adjacent young Ligurian. In half an hour afterwards commotion commenced in this hive, and on listening at the entrance I heard the invariable fluttering sounds so long familiar to me, as the sure indication of the queen being encased. The queen of this hive I greatly valued in consequence of the brilliance of her colour, and I immediately took steps to rescue her from her very equivocal position. Unfortunately the hive was a straw one, but in ten minutes or so I had all the bees driven out into an empty skep and removed a dozen yards off. I released the queen, but so terribly affrighted was she of her adversaries, that heavily fertile though she was, she took flight and returned to the old stance in the bee-house where I secured her. I returned her to the driven bees, but she was again seized by some of them, and in my endeavouring to rescue her from her persecutors, she for the second time took flight and returned to her old locality. I then seized and kept her in custody for a little time until I considered what best to do in the circumstances. I now thought of separating the unicombe's bees from the Ligurian hive's bees before proceeding further. For this purpose I replaced the Ligurian hive in its old site, and also opened-up the entry to the unicombe-stance, putting an empty hive there. I then allowed the conjoined driven bees to quit the skep into which they had been put at a little distance, and thus each hive's bees gradually betook themselves to their own stances, and I got quit of the unicombe's bees. The captive queen I now introduced to her disconsolate subjects, by which she was received with a perfect hurricane of rejoicing. She was none the worse of all this rough usage. Here, then, there could be no mistake in this case as to the true cause and origin of the encasement of the queen and consequent commotion—namely, the entry of stranger bees, which though admitted themselves without demur, had, nevertheless, surrounded and imprisoned the queen. One other instance on this head will suffice.

On the 30th of October, 1863, I dislodged a young Ligurian queen, artificially reared from a thinly populated hive, with the view of putting her at the head of a hive of black bees. This I successfully accomplished, having first taken away the black queen and about two thousand of her bees. The Ligurian queen was, as usual in such cases, surrounded and imprisoned by the black bees, and she did not regain her liberty till the evening of the 31st, or thirty-six hours after the experiment. With the two thousand black bees and queen I joined a number of the Ligurian bees, and here again the black queen was surrounded and imprisoned for a period of nearly equal duration, though in neither case any fatality occurred.

Second. Queens may be encased or imprisoned when superannuated and infirm from age, or from a natural defect in their procreating powers—such as exhausted fertility.

In 1861, I happened to have in my apiary four hives, Nos. 1, 5, 9, and 13, having very aged queens. No. 1 queen was reared in 1857, No. 5 in 1858, No. 9 in 1857, and No. 13 in 1856. This latter queen was the oldest I ever had in my possession. A few words regarding each.

On the 21st of May, 1861, I removed the queen of No. 1 hive, a Huber, as she was becoming very unprolific and languid in her movements. The brood was scanty and no drone eggs had yet been laid. The withdrawal of the queen produced almost no perceptible change in the hive. There was no commotion of any kind. This induced me to examine the hive minutely, which I did next day, and I found that the decaying energy of the queen had not been unobserved by the bees, but was anticipated as well by them as myself, as two royal cells containing larvæ were well advanced. These were sealed on the morning of the 25th, and a young princess emerged during the night of the 31st. This is another beautiful instance of the wonderful instinct and foresight in the bee in providing against an impending calamity, the probable speedy decease of their decaying queen. So much for No. 1. Now for No. 9, straw hive.

On the 11th of March, 1861, I noticed symptoms of No. 9 hive having its queen encased. On turning it up I found between two of the centre combs near the bottom, a cluster of bees which were densely wedged together. Conjecturing

that the queen was in the midst, I took a small twig and disentangled the bees and found the queen—a very large and swollen one. On liberating her she ascended the combs surrounded by bees, and commotion continued all the afternoon. This queen was nearly four years old. On March 23rd, I again found the hive in great commotion. On turning it up the bees were all scattered throughout the hive searching in all directions, but no clustering was observed. I drove the hive to ascertain its true condition, but found, as appearances indicated, that there was now no queen. She had disappeared since the first commotion on the 11th. I then joined the bees to another hive.

I would now particularly draw the attention of the scientific apiarian to the cases of Nos. 5 and 13, inasmuch as in addition to the phenomena now under consideration being manifested, other and not less mysterious and wonderful phenomena presented themselves—viz., those of aged but hitherto fertile queens becoming drone-breeding queens only. The very interesting nature of these revelations will, I hope, excuse my giving some additional details, not otherwise necessary, under my present subject; but the two phenomena in question are so intimately allied, nevertheless, that I can scarcely avoid alluding to them. I shall endeavour to condense details as much as possible.

On the 2nd of November, 1860, I noticed the first commotion in box-hive, No. 13. On March 23rd, 1861, I again noticed similar symptoms occurring in this hive, which, moreover, showed great dullness and inactivity. Appearances were suspicious. On listening I heard the usual fluttering noise indicative of the queen being surrounded. I immediately examined the hive (it was a bar-hive with glass sides), and found a cluster of bees the size of an apple, near the foot of the combs. I endeavoured by a twig to disentangle the bees which were tenaciously clinging together. I might have rolled the cluster along the board like a ball, as I once did, without separating the bees. Great numbers collected around during my manipulations, and the queen escaped me. The cluster dispersed and all moved upwards among the combs, and quiet was restored. I examined this hive again on the 26th, and found the bees still very numerous and all quiet, but no appearance of young bees. There was little farina carried, and the bees were indisposed to work. Its queen (1856), was now nearly five years old.

Wishing to see how such a hive would receive another queen, I accordingly presented a fertile one to it; but though the bees caressed and fed her at first, she was afterwards cast out during the evening dead. On the 24th of April I observed two or three small drones showing themselves, which I may here say I always look upon with no favourable eye. On the 9th of May, seeing that no young bees were produced, and that the whole appearance of the hive indicated that the queen must be in an abnormal condition, I drove the bees to ascertain the cause of its inactivity and declension. I failed, however, to secure the queen. Severing the side connections, I drew up every comb, but could not find her. I then removed all the combs into a frame hive. On examining these, not a single worker egg or young bee could be seen; all was drone brood. I counted seven hundred in all stages, all in common worker cells, and in several of the cells two or three eggs were found deposited. The operation having been performed in the evening, I left the hive in a very unsettled state. Next morning they still remained so. I now examined the spot where I had extracted the combs, and found the queen apparently quite dead; she had fallen accidentally and unobserved, and had lain exposed on the cold ground during a somewhat frosty night. I succeeded in partially restoring her to animation, but this was all. I then gave her to the bees, the best resuscitators. They gathered around her and flapped their wings with joy. They tried to feed her, but she was all but motionless. I left her to their care, and in the afternoon, on examining the interior, I found the queen completely revived and traversing the combs as before. This is a notable example, among others which might be given, of the tenacity of life in the queen bee, and her capability of enduring such a degree of cold so long without destroying the vital energy or impairing, indeed, any of her functions. The day following she began again to lay, and on the 15th of May upwards of three hundred eggs were laid. She was evidently a very aged queen, had tattered

wings, with an abdomen exceedingly thin. I again examined the combs on the 21st, and found the queen still laying apparently drone eggs all in worker cells. As the bees were now reduced to about seven hundred in all, and no new feature manifesting itself, I took the queen away, and having drawn up a frame, I introduced a new fertile queen to a portion of the bees to see if they would accept her. In ordinary circumstances I knew what the consequences were likely to be, but I wished to ascertain if the bees in their peculiar circumstances might not receive her. I was glad to find the bees made no attack upon her, but appeared rather to treat her kindly. Noticing this I lowered the frame for half an hour, and then examined it, and found the queen imprisoned in the midst of a cluster of bees. On extricating her I found she was much injured, and sinking already under the effects of ill-treatment and stings. I distinctly saw a bee sting her underneath the body; she died soon afterwards, and was extruded. I then tried them with a piece of brood-comb containing eggs and young larvæ, but they failed to rear a queen, and I ultimately joined the residuary bees to a neighbouring hive.—J. LOWE.

(To be continued.)

### SWARMING VERSUS STORIFYING.

YOUR Renfrewshire correspondent seems to think that my storified hives must have been improperly treated, or they would not have contrasted so unfavourably with the stocks devoted to swarming. I will briefly state the course pursued, and shall feel obliged for any information which will enable me to obtain a better result for the future.

In 1864, out of six stocks three were storified; call them A, B, C. A Was an artificial swarm of May 19th, 1862, and is located in a 14½-inch Woodbury frame-hive. In 1863 it was storified, and yielded 25 lbs. of very pure honey in a super, and on the 23rd of June, when I was from home, sent out a very large swarm, which would have been returned but for my absence; however it made a very heavy hive before the end of July.

Early in May, 1864, this hive (A) was supered with a box (furnished with bars and guide comb) 13 inches square inside, by 7 inches deep, and the bees at once entered, and commenced operations. When the super was two-thirds filled, a square frame without either top or bottom was slipped in between the stock hive and super, and when the hive became crowded, a second frame exactly like the first—i.e., 3 inches deep by 13 inches square inside, was introduced as before, between the first frame and the stock.

In spite of the ample accommodation thus afforded, assisted by ventilation, the hive threw out a swarm on the 18th of June; but after capturing the queen, I returned the bees to the parent hive, and when piping commenced excised all the royal cells, leaving the senior princess at the head of the colony. The bees ultimately nearly filled the top box with fine honey, and carried their combs down into the inserted frames, but the total yield of honey did not exceed 32 lbs.

B Was a fourth swarm hived May 26th, 1863, in a Bevan bar-hive, 11½ inches square, by 9 inches deep, containing eight bars. This swarm was in the first place hived merely for the sake of testing the quality of the queen, but it did so wonderfully well, though only a very small swarm (not only filling the box with comb, and working in a bell-glass, but also requiring a nadir towards the end of July), that I kept it on as a stock hive.

This was supered with a box of the same size as the stock hive, but the bees were very slow in availing themselves of the room afforded to them, and shortly after taking possession of the super, sent out a swarm. In this case the queen was a valuable one, so having excised the royal cells, I returned the swarm with the old queen; two shallow boxes were successively introduced between the stock and super, and towards the middle of July the hive was also nadired, as the bees were getting short of room, though they had not quite filled the super. This hive yielded about 40 lbs. of pure honey.

C Was a second swarm of 1862, June 4th, and is located in a ten-frame Woodbury hive. In 1863, I obtained four swarms from this hive. The third swarm was sent to "A

DEVONSHIRE BEE-KEEPER," who can attest its strength. It was hived on the 23rd of May, and had given me 9 lbs. of honey before it left my apiary. The fourth swarm has been already alluded to. The queen at the head of this hive (c) in 1864, did not prove very prolific. The hive was supered, and afforded 30 lbs. of very pure honey.

In conclusion, I may observe that Dzierzon affirms that the produce of a divided hive will greatly exceed that of one which is not permitted to swarm, and my own experience induces me to concur in this opinion, especially if the swarms are early, so that the progeny of the young queens are able to assist in collecting the honey harvest in the latter part of June, and beginning of July. If a stock is late in swarming, the young bees would for the most part be too late for the harvest, and such a stock might give a better result if storified. I never permit any of my hives to hang out at the entrance for more than one day, as I can always find a more profitable occupation for them.—J. E. B., *Wolverhampton*.

REMOVING BEES TO A DISTANCE.

If you will kindly advise me how to transport one of Gale's (of Alton) box-hives, with the bees and honey to a distant country, I shall be much obliged.—C. R.

[Stop all apertures in the top or sides of the box by means of perforated zinc, then raise it from its floor-board, invert it, and confine the bees by tacking a piece of perforated zinc over the bottom of the hive. Pass a cord round it, and send it, still in an inverted position, in charge of a careful messenger, who will not commit it to the tender mercies of railway porters.]

DIMINUTION OF WEIGHT IN BEE-HIVES DURING OCTOBER AND NOVEMBER.

THE following is the loss in twenty stocks that were weighed on the last day in each month:—

No.	Loss in Ounces.			No.	Loss in Ounces.		
	October.	November.	Total.		October.	November.	Total.
1	30	22	52	11	38	41	79
2	24	32	56	12	35	36	71
3	35	39	72	13	23	24	47
4	31	17	48	14	32	43	75
5	35	27	60	15	37	54	91
6	32	31	63	16	28	36	64
7	18	15	33	17	33	34	67
8	34	29	63	18	40	39	79
9	33	27	60	19	44	32	76
10	30	27	57	20	32	40	72
Total consumption, or loss, of twenty stocks				640	605	1245	
Averaging per stock				32.0	30.25	62.25	
The mean average loss per stock for the last ten years				40.76	25.95	66.71	

This shows that the consumption in October was 8½ ounces per stock less than the average of the last ten years; but in November the loss was about 4½ ounces per stock more than the average. My bees were out almost daily in October, and were collecting from borage, mignonette, and French poppies, and in November they were out frequently, and I saw them carrying pollen into the hives as late as the 21st of November.—WILLIAM CABR, *Newton Heath, near Manchester*.

LIGURIAN BEES IN AUSTRALIA.

THE apian readers of THE JOURNAL OF HORTICULTURE will be pleased to learn, on the authority of Mr. Edward Wilson, President of the Victoria Acclimatisation Society, who has recently revisited this country, that the Italian stocks exported from my apiary to Australia in 1862, are doing remarkably well, and have multiplied prodigiously in a climate which appears to be most favourable to them.—A DEVONSHIRE BEE-KEEPER.

RANCIDITY IN BUTTER.

I WOULD suggest to your correspondent "COCHIN" to churn each cow's milk separately, by which means he will be able to discover if the rancidity arises from any inward

complaint in either of the animals, for a cow suffering from such a complaint would cause the butter to be rancid. Dry salt instead of brine will cause rancidity sometimes. A hot hand making up the butter will also cause it. Skimming too often, and mixing the cream altogether, is a cause. Meat hung up in a dairy, whether fresh or salt, would also cause it; and lastly, if the dairy is near a stable in which horses are kept, the smell from the ammonia will invariably cause rancidity.

I hope "COCHIN" will succeed in finding a remedy, and make it known in your Journal for the benefit of your readers generally.—JAS. NOON.

OUR LETTER BOX.

PIGEONS FORSAKING THEIR HOUSE (*An Irish Subscriber*).—This, I fear, arises from something objectionable in the entrance. Are they there disturbed by cats, or does the ivy so cover the roof and alighting-board as to make their settling thereon inconvenient? Pigeons do not like resting among leaves, not being arboreal in habits; or are the birds of a wild sort, and consequently disapprove of the place as being too public? In that case you might try a more tame variety, and when they are confined let the entrance be so guarded that they can go out and see about them, so as to learn by eyesight the exact position of the way in.—B. P. B.

ORNAMENTAL HEN-COOP.—"F. P." would be obliged by the suggestion of an ornamental hen-coop. If any drawings which we approve are sent to us in answer to this appeal, we will have them engraved.

HATCHING APPARATUS (*Q. C. H.*).—Write to Mr. Melville, 20, Glaskin Road, South Hackney, London. He is Mr. Geyelin's agent.

SUPERIOR EGG-EATING FOWLS (*C. S. J.*).—Spanish are excellent layers, but not better than the Crève Cœur or La Flèche. They are hardier. The Hamburgs are great layers, but none of these sit. As we do not advocate crosses, and as such must be the result of mixing several breeds together, we should advise you to keep Brahma Pootras. The advantage will be, that they are not only vast layers, but they are excellent sitters and mothers. If you have several layers, you may have several breeds, and then we recommend the three first named.

SIZE OF POULTRY-HOUSE (*Idem*).—A wooden house is all that is necessary for any poultry. If you keep fowls by hundreds, you should have several houses. There are few places in the country that are not already provided with them. Old cow-stalls, calf-pens, barns, cart-houses, wood-houses, lean-to's, anything will do. To roost a hundred and keep them healthy, you want 30 feet by 25.

POLAND FOWLS (*Old Subscriber*).—The Golden and Silver Polands are the hardest of the breed, and capital layers.

LARGE SUPPLY OF EGGS (*F. C.*).—You will want 700 hens, besides cocks, of different ages, in order to insure a succession of 1500 eggs daily. They will cost at the lowest estimate £1500. They would require at least eighty acres of land to be kept healthy and profitably. Four men would look after them, but they could only do it by having everything necessary brought to their hands. They must have nothing to fetch, or grind, or thrash. All their time will be occupied in tending and feeding. Any poor land will do, and it will be better in every way for your pursuit than good land. Pens and sheds cannot be too homely, and need not entail any great expense. We do not advise you to take such a contract without first assuring yourself of efficient and certain help in the event of your plans failing. A much safer and more reasonable agreement would be to undertake to sell all your eggs at a certain price to one person all the year round. In such a contract as you speak of, inclement weather—such as snow, cold easterly winds, or the appearance of an epidemic among your birds would be very serious to you.

SCURF ON LEGS OF COCHIN-CHINA FOWL (*E. J. W.*).—The scurf is not important if it has not eaten off the feathering. Put only one cock to the two hens, you will have to remove him later in the season. Two cocks would be not only ridiculous but mischievous.

BAKES (*F. G. R.*).—They are also called "Creepers." The following is the description given of this breed in the "Poultry Book for the Many:—"They resemble the Dorkings in everything but extreme shortness of legs; these are only 2 inches long from the hock to the heel; comb single; body round, plump; tail ample, and in the cocks well sickled; plumage white, variously marked with black; eggs average size; hens good layers and good sitters. Weight of cock averaging 6½ lbs.; of hen, 5½ lbs. They seem to be of Scotch origin, and are described by a good judge as 'hardy, a good variety, and well adapted for the table.'"

LONDON MARKETS.—JANUARY 23.

POULTRY.

The supply is small, and trade dull. There will be little alteration till the meeting of Parliament. The enormous supply of Pheasants has had much to do in depreciating the price of fowls; and so far as these luxuries can be considered as public and ordinary food, we may say they have this year been within reach of many who have not before ventured to think of them.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 44.9°, and its night temperature 31.9°. The greatest heat was 57° on the 3rd, 1850; and the lowest cold, 8°, on the 31st, 1857. The greatest fall of rain was 0.75 inch.

THE MODERN PEACH-PRUNER.

No. 2.

THEORY OF VEGETATION.

WITHOUT having the pretension to enter very largely into the difficult subject of vegetable physiology, and wishing at the same time not to exceed the limits originally proposed for my notes, it will, nevertheless, be proper to devote two or three chapters to an examination of the principles which regulate vegetation.

In this case theory must necessarily precede and govern practice, nor is it prudent for the horticulturist at any time to separate them.

It is not always at first setting out that the amateur, eager as he may be for information, is in a position to profit by the numerous works on the principles of vegetation. From many causes he generally reverses the natural order of things, and begins by experiments based on the teaching of unlearned and often deeply prejudiced men. The consequence is, that after a series of years passed in alternate success and failure, he finds himself compelled to return to first principles, and to make an attempt, often futile, to unlearn nearly all he formerly knew; and this often occurs when his practical manipulation had attained a pitch which, had it been regulated by a sound acquaintance with the laws of vegetation, would have placed him in the highest rank. It is obvious, then, that a treatise on Peach pruning, such as this one, must commence at the beginning. It shall be the especial object of the writer to make this portion of the subject as brief and as simple in detail as possible, while nothing that is important to the amateur will be omitted.

Commencing by an analysis of the organs of plants we find that in general what are designated as the elementary organs, or the primitive formations of matter, are known as cellular and vascular tissues. The cellular tissue appears first, and is composed of small cells, while vascular tissue is composed of tubes, pierced with lateral openings, and enclosing the original cellular tissue between them. Cellular tissue forms the softer portions of plants, and vascular the harder portions.

Roots are composed of the neck or collar, of the taproot from which the roots ramify, and of fibrous rootlets, at the extremities of which are the spongioles, which from the soil absorb the nourishment of the tree. The spongioles, as seen under a microscope, are composed of cellular tissue, and are of the greatest importance to the life of the tree.

The trunk of the tree is composed of the pith, the ligneous body, and the bark. The pith is formed of cellular tissue bound together by the tubes of the vascular tissue. In this position these tubes act as vessels of the medullary canal. From the natural deviation of these vessels arise the leaves and the buds,

and after these the green or growing shoot. The ligneous body lies between the pith and the bark. If we cut through the trunk transversely, the ligneous body is seen in the form of concentric layers, each the growth of one year. Between these layers are the medullary rays which connect the medullary canal with the circumference. If, however, the trunk be cut through vertically, the ligneous fibres of the layers are seen to be formed by the union of vessels derived from the base of the leaves, and reaching downwards to the spongioles. The ligneous fibres, produced by the upper leaves, lie over those produced by the lower leaves. Thus the exterior layers are the latest deposited and the youngest.

The ligneous body itself is composed of hard wood or heart, and of alburnum or soft wood. The heart, formed of the innermost layers, is composed of tissue, which material deposits have completely filled up. The alburnum, or recently-formed ligneous substance, is situated between the heart and the bark of the tree. The outer layers contain the sap-vessels, which perform their important functions in proportion to their formation.

The bark comprehends the liber and the cortical layers. The liber is the interior portion of the bark, and covers the alburnum. The liber is the seat of vitality in the tree. It is composed, therefore, of a certain number of thin layers of vessels having their origin at the base of a leaf, and their extremity at the spongioles. While, however, in the ligneous body the exterior layers are the latest produced, in the liber, on the contrary, the newest are the innermost ones. The cortical layers are those formed by the oldest ones of the liber. In young subjects the liber is covered with thin tissues called respectively inner and outer epidermis.

The bud, situated at the axil of the leaves, is the rudiment of the young shoot. It is formed by a deviation of the vessels of the medullary canal.

Leaves are composed of footstalks and the blade or body of the leaf. The footstalk of the leaf is formed by the vessels of the medullary canal. These vessels ramify in the tissue, and form the channels of the sap. The body of the leaf is formed of cellular tissue covered with a thin skin or epidermis, which is pierced with innumerable apertures called stomata. In fact these stomata or mouths are to be found on all growing portions of vegetables, not only on the leaves, as before stated, but also on the shoots themselves, and on the fruit. Their functions are very important in vegetable life, as will be explained presently.

Flowers are composed of floral envelopes and of sexual organs. The floral envelopes are the calyx and the corolla. The divisions of the calyx are known as sepals, and those of the corolla as petals. The sexual organs are the stamens and the pistil. The stamens are the male organs of plants. The anther at the extremity of the stamen contains the pollen or fertilising dust. The pistil is the female organ of plants, the extremity of which is called the stigma, and the base the ovary, while the intermediate space is called the style.

The fruit is composed of the pericarp, a fleshy sub-

stance which is formed of cellular tissue, and of the seeds. The seed contains the rudiment of a similar plant.

The embryo comprehends the radicle or rudiment of the root, the plumule or rudiment of the stem, and cotyledons, whose office it is to supply nourishment to the young plant before the appearance of the leaves.—T. COLLINGS BREHAUT, *Richmond House, Guernsey.*

## HARDY FERNS:

### HOW I COLLECTED AND CULTIVATED THEM.—No. 9.

In writing my experiences of Fern hunting in Cornwall, my pen has a lingering habit, and my thoughts wander away from the Ferns to the people with whom I was thrown into pleasant association during my Cornish visit, and upon whose characters and habits of life, Mr. Aitken's influence was telling perceptibly, telling upon rich and poor in a manner that made itself felt by every visitor to Penzance.

The man who drove the donkey-chair, the miner who showed us short cuts over terrible precipices, each had some tale to tell of wonderful conversions made with noise and clamour, in which it seemed to me, that the worse the "ground," the better the "seed sown" was supposed to thrive. What I heard did not seem to fit in with my knowledge of the usual workings of the "Good Power" in the natural world around me. I remembered the *Lanceolatum* dwindling away on the barren wall, and I asked what sort of lives followed upon these noisy conversions? The answer was as I expected—a dwindling away afterwards. Yet not in all characters was this reaction to be observed. Upon some Mr. Aitken's strange power for influence fell with the highest results for good—stirring up the slothful, deepening the seriousness of the already serious, and giving to the naturally timid a moral courage, unlike the courage of this world—it was the influence that a mind really in earnest (whether for good or evil), must ever have upon the minds of those around him.

As the memory of these days comes back to me, a bright light seems to fall on the fragile Maiden-hair Fern, so graceful in form, so tender and delicate in growth. Hiding itself away from the glare of the sun, and the haunts of men, in its own home—the home of Heaven's choice—how green and lovely it is! adorning the rough crevices of the time-worn rock, and in its sheltered nook, even in the depth of winter, ringing out to Nature's God its little psalm of praise, as a stray wind blows on the tiny pinnules. Transplanted, the delicate fronds shiver in every breeze, and perish when the cold wind of heaven touches them.

*Adiantum capillus-Veneris*, is another of my representative Ferns.

Fragile and delicate as the Fern was the young friend who first introduced me to its haunts on the rocky banks between Lelant and St. Ives, in a wondrous walk, where every beauty of earth and sea and sky seem blended together in harmony. As we walked and talked, rabbits came out of their burrows, peered at us, and then scudded away amidst the Gorse. I had never seen *A. capillus-Veneris* in perfect growth in England, and none but one to whom its fastnesses were well known would have found it on this day. I was cautiously descending a very slippery bank on the verge of a sharp descent to the sea, whose waters were murmuring below, when I heard a joyous cry—"Look up!" and there I saw the Maiden-hair, not one plant but many, peeping out of moss dripping with trickling water, and nestling into the crevices of the rock. Some of the plants were tender wee things; but I think these answered best in cultivation, for out of this morning's raid I have had about twenty beautiful Ferns, besides those that my friend took away. I can recall the very scene, the dark eyes of my friend, out of which the pure light of a chastened soul gleamed, brightening with delight at the discovered treasure, the eager step, the radiant, and then the paling cheek. I see it all as I look at my Ferns, and remember that that ardent spirit is at rest for evermore; safe in that blessed home towards which he had from his earliest years been walking, side by side, as it seemed to those who knew his quiet, holy life, with Him whose love constrained him to a life of self-denial and self-devotedness, to the spiritual welfare of all around him. His highest ambition was, when

old enough, to be a missionary priest, to spend all his talents and his life in his Saviour's service. Ere that longed-for day of toil dawned, rest was given, and the earnest choice of the heart, and the fixed will of the mind, was, we may humbly trust, taken for the working of a body too frail to fulfil its longings, by that "Only Master, who in service takes the will for the deed."

In our uphill scramble to regain the path to St. Ives, we met a man who looked at us with very displeased eyes. "Where had we found the Fern?" Then he invited us to his cottage, and showed us, oh! so very many imprisoned Maiden-hairs, languishing in captivity, which he had sought for and planted to sell to stray tourists; so that shortly every plant must be gone.

St. Ives is one of the most picturesque towns in England. The grey houses jut out on a tongue of land into the sea, which chafes around and upon them, quite ready, in appearance at least, to swallow them up, as it swallowed the land of Lyonesse long ago. I found no other rare Fern at Lelant or St. Ives, but there are many curious wild plants, and the churches are well worth a visit, particularly that of Lelant.

I planted the specimens of *A. capillus-Veneris* in pots half full of drainage, with peat earth, and a little silver sand. They thrive well in cultivation, but they must be housed during winter in the north of England. In Devonshire I have succeeded in making them live in the rockery all the year. A short distance from Nice, in France, there is a grotto, called the grotto of St. André, the whole roof of which is a mass of *capillus-Veneris*. I drove there one Christmas Eve. The portals of the cave were bright with flowers and Myrtles, and the inside was like fairyland, from the waving of the beautiful tresses, as they hung from the dripping roof high above our heads. I took a hint from the cave, and keep my Maiden-hair thoroughly drained, and constantly watered over the fronds, and I have seldom seen finer plants than the Warwickshire ones.

I have not mentioned any particular haunts of *Lastrea recurva*, for it grows plentifully everywhere; the well-drained banks of old ditches seem to suit it best. One of the very prettiest *Adiantums*, a foreign one, for a rockery, is the *Pedatum*. It is exceedingly hardy, increasing rapidly, and the tuft of bright pinnæ attached to the shining black stalk spreads out in shape like an inverted umbrella, making the entire mass like a diminutive Palm grove.

Another good hardy Fern is the *Cyrtomium falcatum*. This Fern has the dark shining look of the Holly, and preserves its brightness when the other inhabitants of the fernery are lying dead around. It is a native of South America. In a small hamper of Ferns lately sent to me from Otago, in New Zealand, I discern the early promise of *C. falcatum*, but as I have not had the opportunity of studying the native Ferns of Otago, I cannot be very positive about it, and I shall not venture it out of doors till I learn its inclination more fully. The fructification of the *Cyrtomium* is exceedingly curious. The shape of the frond resembles a leaf of the *Berberis aquifolium*, and the back of each pinnule is dotted over with round spore-cases in the neatest manner imaginable.

There is a great deal of pleasure in tending the foreigners of a fernery, particularly when they benignly adapt themselves to our miserable climate. Torn from the glories of a tropical forest, where their kindred tower their giant forms towards Heaven, do they never pine for home? Does the *Cyrtomium* never long to change the twittering sparrow and sober robin, for the gay chatter of the parrot, or the wisdom of the statesman-like macaw? Does it miss the light spring of the agouti, the merry race of the raccoon? Does it hold out its arms in vain for the embrace of the trailing parasite, decked in a thousand gorgeous hues? Does it sigh for the glow of the noontide sun, as its rays penetrate here and there the thick shade of the forest, lighting up the bright insect world that lies in drowsy ease around? For my pleasure it is content to forego all its grand, happy past, and live in the quiet fernery, alone and forgotten by all but the grateful hand that supplies its wants, remembering it is a stranger in a strange, uncongenial land.

Another foreigner that is very easily cultivated, and very lovely, is the *Polystichum proliferum*, the fronds are so

finely cut that it has the appearance of lacework. It increases rapidly, a number of small plants collecting round the old root, which when planted out soon grow.

There are many other foreign Ferns that look exceedingly handsome in a fernery, but I have only cultivated those I have named. I am hoping to find several of the Otago Ferns hardy enough to brave a Devonshire winter; but I shall not venture them out till I have proved them more surely.

I have never in my wanderings found either the *Woodsia ilvensis* or *hyperborea*. I have heard of them in Scotland, and again at the Lakes, but I am obliged to confess that I have met with neither of the plants either in its wild or cultivated state, so that I have been unable to buy one from any collection I have been over. I believe they are too rare and uncertain in growth to be trusted out of doors, even during the summer.

Another Fern I have never found is the *Asplenium fontanum*. I have had several plants of this which I have tried to harden sufficiently to trust in the fernery, but they are, at best, unhappy-looking, and the slugs devour the little juicy fronds, which are about 2 inches long, and in appearance like the young fronds of *Asplenium lanceolatum*. In a cool greenhouse *fontanum* grows well, throwing up a compact cluster of rather pale green fronds. I plant it in a pot half full of drainage, and leave a few bits of broken flower-pot amongst the soil in which I plant it. I venture one plant out in the summer, as I like to see at a glance all my specimens gathered together. A well-stocked fernery, and "Moore's Handbook," will teach a beginner in a couple of lessons more than a month's study of all the learned books on Ferns published. The biography of a good man is a pleasant thing to read, but to see that man face to face, and to know him personally is far better. After this acquaintance by sight, the study of little peculiarities, aided by magnifying glasses, and by the experience of others, is made doubly interesting.—*FILIX-FEMINA*.

#### IVY.

Few creeping, trailing, or climbing plants merit so much at our hands as the Ivy (*Hedera helix*). It is most accommodating as to soil and situation, as it will grow almost anywhere, in sunshine or in gloom, and it ever gives a pleasing and lively appearance. It flowers at a time, when

"The rain and wind beat dark December,"

at a time, too, when its leaves of vivid green are so much sought after for the decoration of the "wide hall and cottage small," in celebration of the Christmas festival. It blooms at a season when all the rest of nature is dead alike to the botanist and lover of flowers. Newly-introduced plants we praise and pet; but this rare old plant that clings so tenaciously to the old castle and tower, we do not fully appreciate. From the days of the Druids down to the present time this plant has been held in high repute for covering old buildings, and giving them a more ancient appearance.

Ivies like a dry, well-drained soil, but will grow in almost all soils and situations, and where scarcely anything else will succeed. That is one of their greatest recommendations. For covering unsightly buildings or palings, and in soil unfavourable to the growth of any other plant, the Ivy has no rival; if planted at the foot of a tree all but dead, it quickly converts it into a lovely object; if trained on arbours it adds much to their coolness in summer, to their warmth in winter, and to their beauty at all seasons; and for training on wire or wickerwork round beds it is especially suited. For forming belts in borders the Ivies are well adapted; for blending with other plants in suspended baskets in cool conservatories they are effective; and for ornamenting rock-work, the entrances of caves or caverns, and for rambling over ruins they have no equal.

Ivy is propagated naturally by seeds (the berries are eaten greedily by wood pigeons, blackbirds, and other birds, the blackbirds occasionally feeding their young with them), but under cultivation it is best increased by layers. The most suitable time to do this is in spring, a little before growth commences in March. Having drained a 24-sized pot well, half fill it with rather light soil, and plunge it to

the rim, where a moderately strong shoot can be placed across it with a foot of growth beyond. Bending the shoot into the pot, fasten it down in the centre with a peg, then twist the growing end round the inside of the pot, covering with earth, and finally bring the growing point to the centre of the pot, tying it there upright to a small stick. By coiling the stem round the inside of the pot more roots will be emitted than if the stem were simply placed across it, and it will better endure separation from the parent. The shoots may be layered in the soil around the plant, and though they root with equal certainty the plants cannot be so conveniently moved from place to place, nor can they be so safely transplanted. In either case they will be well rooted by autumn, when they may be detached from the parent, and if in pots removed, plunging the pot in coal ashes in a sheltered situation. The rooting of the layers will be more rapid if they are watered occasionally during dry weather, especially if in pots.

In spring they may be potted in nine-inch pots if large plants are wanted for planting out, and a stake about 3 feet high placed in the centre, in order that the shoots may be fastened loosely to it as they advance. Though Ivy usually grows amongst old rubbish, a little well-rotted manure mixed with the soil will assist the growth of the plants. Shoots layered in the soil around the plants may be separated from the parent in the autumn, and potted in six-inch pots, plunging them in coal ashes in a sheltered situation, and tying the shoots to a neat stake. In this position they may remain another year, watering them in dry weather, and by the autumn of the second year they will be strong plants 3 feet or more in height, having a profusion of lateral or side-shoots, and fit for planting in any position, and to give an appearance at once.

Ivy may also be increased by cuttings. Select young shoots in summer about 1 foot in length, and with a few inches of the old wood, and insert them 6 inches deep and the same distance apart in a shady border of light sandy soil, trimming the leaves off the part inserted. They will root much more certainly and quickly if covered with a frame and lights, shaded from bright sun, and kept in a moist soil and atmosphere, and for the better or more tender variegated kinds a frame is desirable, as they root rather slowly in the open air. The most suitable time for inserting the cuttings I find to be June and July; but they will strike at almost all seasons, if care be taken to select the young healthy growths with a portion of the old wood, especially those having rooting formations, as when running along a wall or over the soil. The cuttings will be well rooted and established by autumn—that is, presuming them to have been put in by July; they may then be potted in six-inch pots if of the strong-growing kinds, or into a less size if of smaller growth, and plunged in coal ashes in a sheltered situation under a fence or wall. If such a position cannot be afforded they should be protected in a frame, and for some kinds a slight protection in winter is necessary, especially in exposed situations.

The plants should remain in pots until they become strong, when they may be planted out, it being desirable to employ strong plants only, for the positions they have to occupy are frequently not conducive to free growth: besides, when strong, they take more readily to any place, and give an appearance at once. In planting the soil should be taken out for a space of about a yard, and about a barrowful of sandy loam (that from turves is to be preferred), well rotted manure, and leaf mould in equal parts, to each plant, will give them a start. This addition of fresh soil is particularly desirable when the plants are against walls, the soil near which is for the most part formed of old rubbish, and when planted around old stumps of trees, where the soil is generally exhausted.

For planting against walls that are a considerable height the common Ivy (*Hedera helix*) has no rival, and it grows equally well on all aspects, but is best suited for a northern one. It is also the best of all for climbing up the boles and along the branches of trees, and may frequently be seen covering many trees to a height of 40 or 50 feet from the ground. The finest sight I have seen of this kind was the trunk and majestic arms of an Oak covered to a height of 45 feet. It had six arms at 12 feet from the ground, and these were covered for 10 feet from the trunk, and 12 feet

above them there were three other arms, each 6 feet long, and then the Ivy rose on the trunk in one unbroken column for 21 feet. The effect was most beautiful. Another fine example of Ivy-covered trees existed at Harden Grange, Bingley, Yorkshire, where two large trees, one on each side of the carriage-drive to the house, were so covered, resembling a gorgeous triumphal arch of massive proportions. This fine ornament was seriously injured by the severe frost of December 25th, 1860.

When planted against a building Ivy should be nailed to the wall, and trained up trellises, or fastened to those objects it may be desirable to hide, and the shoots as they grow regulated, so as to cover the surface as quickly as possible. I do not know whether it is generally known or not, that if trained over wirework it forms one of the coolest and most beautiful of arbours.

The common Ivy is considered to be distinct from the tree Ivy (*Hedera helix arborescens*), but it is my impression they only differ in the treatment to which they are subjected. All the forms of *H. helix* are tree Ivies if allowed to grow to a flowering state without the usual clipping; but the most desirable for their tree-like appearance are *H. helix arborescens*, and the yellow-berried sub-variety (*H. helix baccifera lutea*, which is synonymous with *chrysocarpa*, there being a *H. helix chrysocarpa* from Northern India with narrow-lobed leaves, having silvery veins), but it, like all the others, is no tree unless it has something to climb up, and then it is a tree 10 or 20 feet high, just as the object is high or low, and whether it is cut or not. Cut all the tree Ivies every other year, and they are every one climbers or trailers, but leave off cutting them and they all form bushes or trees from 4 to 40 feet in height, just as the object to which they cling is high or low. For planting against railings, trunks of trees in arborettums, and in shrubberies, the three forms mentioned are unequalled, and to them may be added *H. helix aurea*, with yellow leaves when appearing, but in other respects not differing from the species; *alba lutescens*, with white-belted leaves, and the golden clouded-leaved form (*aurea maculata*), are eligible for such purposes; also the small yellow (minor *lutea*). The silver-margined form (*marginata argentea*) may also be added, but it must be borne in mind that variegated Ivies are not so hardy as the green-leaved sorts, and neither they, nor, in fact, any of them, are suitable for planting in bleak situations. In the majority of gardens, sheltered as they mostly are by trees, most Ivies will be sufficiently hardy to bear exposure in most situations. For covering a tree stump quickly, Rœgner's Ivy (*Hedera Rœgneriana*), and the Irish, especially the arborescent form (*H. canariensis arborescens*), are very suitable, and, having large green leaves, they are most esteemed for covering buildings on the east and west aspects, *H. canariensis* being the best of all. The tree form, though eligible, is not so good for surface-covering. The Algerian Ivy (*H. algeriensis*), is also fine for a wall, but it requires a south or south-west aspect in cold localities.

These when established should be clipped close every other year with shears, and accumulated dirt brushed from between the stems. The most eligible time to clip Ivy is the first week in April. Where an even surface is desired the loose shoots may be removed in September, cutting to within three or four leaves of the stem from which the shoot takes its rise.

Varieties of climbing habit, and of free but less growth than the preceding, and like them having green foliage, are very suitable for covering low walls. Such are *Hedera taurica*, with small, much-divided, and neat leaves, and its variety *Leana*, *H. poetica*, *pennsylvanica*, *H. helix digitata* (*palmata*), *H. helix crenata* (notched-lobed), *H. helix gracilis* (slender-branched); and for forming a close covering to the wall, *H. taurica*, before named, the yellow-fruited (*H. helix baccifera lutea*, or *chrysocarpa*), *lobata*, *digitata*, already mentioned, and *H. pennsylvanica*, and these are equally eligible for planting by rails, rustic fences, &c.

Of the variegated kinds the most beautiful are the white-belted (*alba lutescens*, identical with the old *H. helix foliis variegatis*), than which no plant gives buildings such an antique appearance, and the silver-margined (*marginata argentea*). A pair of gold-blotched kinds to match are *aurea maculata* and the smaller gold-margined (minor *lutea*). The neatest silvery variety is *H. helix minor aurea*,

with beautiful silvery-marbled leaves, and which is especially suitable for hanging-baskets; and for this purpose the forms of *H. helix marginata* are also well adapted—viz., *Cullisi*, *marginata argentea*, *elegans*, *robusta*, *pulchella*, and major, *elegantissima* being the best of all. There is a variety of the old variegated Ivy, with silver-striped leaves, which in winter has the leaves margined and veined with red. It is an exquisite variety, but I am not able to speak positively as to its hardiness, not having grown it.

Perhaps the most beautiful Ivy is the new Japanese *H. japonica argentea*, recently introduced by Mr. Fortune. It has beautiful silver-margined leaves, very distinct, and there is every reason to hope that it will prove hardy on walls with south or south-west aspects, and in sheltered places.

Besides being indispensable for covering walls and rustic buildings generally, or any unsightly object, Ivy answers admirably for planting on rockwork, the small-leaved kinds being very suitable on account of their clinging closely to the stones, and their small foliage having a fine effect. The smaller kinds are, in addition, especially adapted for training on the wirework of beds, they being equally handsome at all seasons, heightening the effect of the summer occupants, and doing away with much of the dreariness of the flower garden at that season. For this purpose the plants should be planted at about 2 feet apart, and the shoots as they grow trained over the basketwork so as to cover it completely in time, training them regularly and evenly in the first instance, and the afterwork merely consists in trimming the young shoots away to two or three leaves in August, and when the growths become very strong the Ivy should be cut quite close with a pair of shears once in every two or three years, care being taken not to cut the strong shoots or stems, or the part above will perish, or make an indifferent appearance. When the shoots are regulated with a knife or nipper twice annually, in April and August, cutting away the strong and ill-placed shoots, stopping the long, and thinning out where too thick, so as to give an even surface, no further pruning is necessary. The small-growing green kinds are best for this purpose, the variegated kinds being unsurpassed as edging plants, but only eligible for sheltered situations.

Then, for forming very ornamental borders the different varieties of Ivies are admirably suited. In most gardens there are many borders that are so shaded with trees that few if any plants will grow in them. I should be very sorry to lead any one to conclude, that no place can be too much shaded for the growth of the Ivy; but it is never seen in perfection except in a north or north-east aspect, or in places partially shaded from the sun's rays. In the shade it grows more freely, and the foliage is of a finer hue, whilst in the sun it soon becomes stunted in growth, partaking of the character of a bush, all its vital forces being directed to the production of seeds, as if nature foresaw that its fate was sealed: hence the provision made for the continuation of the plant. Though adapted for growing in shady places it will not do well in intense gloom; but for surfacing under the shade of large trees where no other or but few plants will grow, quite as much on account of the dryness of the soil in summer as the darkness of the situation, Ivies will be found very useful. In fact, the purposes for which Ivy may be used are so various, that I cannot do more than give one or two more examples. Presuming there is a border 12 feet wide overshadowed with trees, with a fence at the back from 3 to 6 feet high, scarcely anything will grow there in consequence of the ground being rendered so dry by the roots of the trees. It is, however, what may be termed a light yet shady border, and this border is bounded by a walk parallel with, but on the opposite side to the fence, the trees being planted in a line with the last, or a little in front of it. To make an ornament of such a border, strong plants of *H. helix* should be put in along the foot of the fence at 2 feet apart, and the shoots trained to it. Alternately with these in the border, at the same distance every way, another row should be planted, and this is to cover the ground, which ought to incline to the walk for a distance of a yard or 4 feet from the fence; or the fence may be planted with the large-leaved Irish Ivy (*H. canariensis*) if variety is desirable. Two feet from the second row a third row of Rœgner's heart-shaped leaved may be

planted at a like distance, and a fourth in like manner, then a double row of the old variegated Ivy, the first 2 feet from the front row of Rœgner's Ivy, and the other 18 inches nearer the front. An edging may be formed of the Pennsylvanian Ivy, or the finely-divided Taurian. This edging may be a foot wide. It would be more effective if it were raised by training the Ivy on wickerwork about 6 inches high. All this border would require would be to train each shoot over the vacant ground, keeping each variety separate; and when the surface was covered the only care would be to go over the border in July, and cut off the shoots that encroached on their neighbours, and those rendering the surface uneven. The shoots ought also to be regulated in the same manner in April. Once in three years the whole should be cut quite close with the shears in April, and all accumulated dirt cleared away.

To form a border of Ivy in the bedding style, plant the first two rows with the common Ivy, which would give a four-foot surface all along the back of the border in addition to covering the fence, then stretch a garden line along the centre of the space left, and at 4 feet from the end, with a radius of 2 feet, describe a circle, which will, of course, be 4 feet in diameter; go 8 feet from this centre, and describe another circle, and so on to the other end. Raise these circles a foot high in the centre with any kind of rich, light, rubbishy soil or compost, and plant the first with *H. helix minor marmorata* as a band round a centre of *pennsylvanica*. The second circle should be planted with the golden clouded palmate form of *H. helix marginata* (*palmata aurea*). The third circle should have *marginata* Cullisi in the centre surrounded with *H. helix major*; the fourth a centre of *H. poetica*, strung round with *H. helix aurea minor*, or small-clouded gold-leaved; the fifth may be the white marbled-leaved Irish (*latifolia maculata*); the sixth, the golden-clouded form of *H. helix (aurea maculata)*; the seventh, the silver-tree Ivy (*alba lutescens*); the eighth, the large-leaved Irish (*H. canariensis*); the ninth, the richly golden-blotched (*H. helix arborescens minor lutea*); the tenth, the fine silver-margined form of tree Ivy (*H. helix marginata argentea*); the eleventh, the golden-blotched Irish (*H. canariensis aurea maculata*); and the twelfth, a full bed of *H. helix*. If these are not sufficient to reach to the centre of the border, then instead of planting every alternate bed with the silver or gold-leaved, it may be formed of a green-leaved kind, and this will extend the length. The other half of the border should be planted in the same manner, either reckoning from the ends, or better from the centre, which should always be of green Ivy, the old sort. The ground between all the beds should be planted with the heart-leaved Rœgneriana, and completed by an edging in front, next the walk, of the very elegant *H. helix minor marmorata*. The beds in which the smaller kinds are planted should be covered with small stones for the branches to cling to and run over, and use low wickerwork for the edging. In a few years this border would be quite a garden in the depth of winter. Presuming further that there were another border like the last on the opposite side of the walk, and a row of trees behind it exactly corresponding with the other, the arms of the trees all but meeting, could anything be finer than to form a dome of wirework at each end, string the space between the trees with strong wire, in the form of arches and festoons, and cover them with Ivy? This might be trained so as to cover the trunks of the trees, if these are at all old; but if they are young and wanted to grow larger, it must be kept away from them, otherwise they will be strangled.—G. ABBEY.

#### THE LATE ASSISTANT-SECRETARY OF THE ROYAL HORTICULTURAL SOCIETY.

ALTHOUGH Mr. Murray has retired from the office he has filled so incompetently, yet, as a warning to his successor, I will note some other irregularities perpetrated by him, such as the members of no society would tolerate.

Fellows of the Society wishing to ballot for Cattleyas and Epidendrums on the 20th instant are required by a paragraph in the "Proceedings" to "fill up a special form, which may be had on application to the Assistant-Secretary. The form must be returned before the 17th." Now those forms

were not ready on the 17th. I believe they were never printed or written at all. But the neglect and irregularity did not end there. The balloting was announced to take place on the 20th at three o'clock, and I know those who attended before that hour, when they were informed that they were too late, for the balloting had taken place at two! But the irregularity did not conclude even there, for the explanation was that a meeting had been held for the election of Fellows, and they had balloted for the Cattleyas and Epidendrums first. Now it is true, yet scarcely credible, that that day there was no power to elect Fellows, for in the "Proceedings" the day announced for such election is the 24th, and not the 20th!

I need make no comment, but after recent changes of names, and recent elevations to the rank of baronetcy, I should not be surprised to see our ex-Assistant-Secretary step forth in an early Gazette as Sir Andrew Muddle.—AN OLD F.R.H.S.

#### LILIUM LANCIFOLIUM AND LILIUM AURATUM.

Is it true in horticulture that in the "multitude of counsellors there is wisdom?" for if so, how is one to act? Some little time ago some correspondents gave the result of their culture of *Lilium lancifolium*, and told us that success rewarded their efforts. Their plans differed slightly from one another, yet it was possible to see that a very similar treatment was adopted by both, although perhaps the objects in view were different; while Mr. Hague, in a late Number, smiles at the treatment they adopted, tells us of his own, which differs very much from the others, and assures us that he, too, is successful in his treatment. "How happy could I be with either," one may indeed say; but as to agreeing with both, that is clearly impossible; and I am driven to this conclusion, that *L. lancifolium* is a much-enduring and cosmopolitan bulb, which will thrive under very opposite treatment. I have observed the same thing with regard to *Vallota purpurea*. One tells you to keep it quite dry during the winter months, another to keep it constantly growing and well watered; and the advocates of both systems assure you that they have succeeded admirably—indeed, I have seen the bulbs thus treated, and am bound to say that they did not seem much to mind which way it was. And so, perhaps, with the Lilies. As to planting one or more bulbs in a pot, that must depend on the taste and requirements of the growers. If, as I suspect in some cases, they are cultivated for exhibition, then five or six bulbs must be put into a pot, but if merely to obtain a good plant with large blooms they must be grown singly. While on this, I should like to know whether your correspondents have found that their bulbs degenerate after they have reached a certain size. I am not the only one who has experienced this, for a very large grower told me a year or two ago that he was obliged to renew his stock from abroad, owing to this cause.

It is sometimes complained of by those who have grown this bulb that they cannot get so many blooms on a bulb as Mr. Hague, for instance, mentions—16 or 18. I am quite sure that this is in some cases impossible. A large proportion of the roots now sold have been raised from seed, and every raiser of seedlings knows how his productions vary in this as well as in other respects, and hence disappointment is often occasioned. Beautiful as this Lily is, it does not make so effective an exhibition plant as one might imagine; the delicacy of the marking, so charming in itself, not giving effect to the plant as a whole.

No more striking instance of the effects of enterprise can be adduced than the present price of that queen of Lilies, *Lilium auratum*. I was with Mr. Standish when his first plants came into flower, and then fifteen guineas was the price. Little more than two years have passed, and now the same sized bulb can be had for half a guinea, owing to the large importations which have been made from time to time. What this bulb is yet to do we know not. When Sir William Hooker described it in the "Botanical Magazine" he called it "probably one-flowered;" but already it has been shown with nine blooms, while Mr. Barron has flowered it with fifteen, and we may expect some gorgeous sights.

connected with it yet. Imagine four or five bulbs in a pot, with fifteen blooms on each.

I should like very much to know if there was anything very remarkable in the plant of Mrs. Pollock for which a first-class certificate was awarded the other day at the Royal Horticultural Society's meeting. A cutting struck in August and kept in a cool greenhouse is no great wonder. Was it as large as a Currant bush? or wherein did the great merit consist? It does strike me that first-class certificates ought to be very carefully awarded, and the reading of the notice does not give one the idea of anything superexcellent; but in this I may be wrong.—D., *Deal*.

#### FRUIT AFFECTED BY SOIL AND CLIMATE— POTATOES.

A WRITER in your Number of January 17th, (page 47), who signs himself "FRUIT-EATER," in speaking of the fruits of America, says that country and this would probably find first-rate prizes in the other's rejections, and he instances some Apples and Pears which are here considered of the first quality as being worthless there. I am not aware that he brings forward any that are considered worthless here as being found first-rate in the States. Nevertheless, without going so far as the United States for proofs of the character of fruits being changed, there is great truth in what he says. Take the Beurré de Rance Pear as an example. Here in our wet climate and heavy clay soil it is in average seasons of first-rate quality when properly matured; whilst in the rich alluvial soil of Wharfedale, five and thirty miles off, it is utterly worthless however treated. It is even different in the vicarage garden at Whaley, only four miles hence, having there more astringency than those grown here, but still very good. Williams's Bon Chrétien, which Dr. Hogg in his "Fruit Manual" says is one of the finest of Pears, is here utterly worthless; and the Glou Morceau, of which he says "A first-rate Pear," although it becomes melting, is always flat and turnipy in its flavour here. It is, however, hardy and bears well.

We have a great deal to learn about the effects of soil and climate on fruits. I quite agree with Mr. Rivers when he says every fruit has its peculiar season, when its true flavour is more fully developed than in ordinary seasons; and that this is not always in the finest years was proved to me in the wet and cold year of 1860. The Louise Bonne and Seckle Pears were finer in flavour from my trees than they have been either before or since.

"FRUIT-EATER" goes on to say, "In Gooseberries we are unrivalled by the produce either of the continent or western hemisphere, and therefore by a strange confusion of thought, similarly exercised in relation to other things than fruit, pass scornfully by what we should rear very delicately were they not so thoroughly un-aristocratic as to grow quite delicious without other help . . . . than our own dull atmosphere. I have seen and heard a good deal of Black Hamburgh Grapes, but have yet to feast my eyes and taste upon any that shall half reach the excellence of the produce of some very plebeian Gooseberry bushes within view from my window."

I concur in every word of this opinion, and think a finely ripened Gooseberry from the old upright-growing Red Champagne, which I remember grew in my father's garden sixty years ago, is superior to any Black Hamburgh Grape I ever tasted; and I also think that if the time and money which have been spent in raising large Gooseberries had been devoted to raising good ones, we should by this time have had Gooseberries equal to any Grapes that ever were grown, for I think that fifty years as sedulously devoted to flavour as they have been to size would have produced something good before now. If "FRUIT-EATER" has any other sort which is equal in quality to the Champagne I should be glad to receive cuttings from him. For many years I attempted to raise Gooseberries from seed, using the berries of the Champagne, but I never raised one equal to the original stock. My great difficulty arose from cross-fertilisation. I had among my seedlings white, green, red, hairy and smooth, all from one variety. This I attributed to the bees, and therefore think, if attempts are again made, the parent tree should be far apart from all others.

Many of your correspondents speak of the Lapstone Kidney as very good; but in describing the quality, the sort of soil in which it is grown should also be stated, or it will mislead. Notwithstanding its excellence I have ceased to grow it, for it is so liable to disease in heavy clays that I never dug as many as I planted. On the other hand the Fluke, which in the light, rich, alluvial soil of Wharfedale is a heavy, waxy, worthless Potato, is in the wet clays of this district of great excellence; and as a proof that it is so, it commands the highest price of any store Potato in our markets.

The growers of first early kinds should keep their eyes open if they wish to raise new kinds, as occasionally, although very rarely, a first early Potato will have a bunch of apples growing and ripening on the stem. If these be carefully preserved, and the seeds carefully washed out and sown in the spring, many early varieties may be raised, some of which may be of great excellence.

I concur with Mr. Barnham in thinking the Beurré Clairgeau a good Pear. Here it is very superior to the Glou Morceau—another instance of what I have elsewhere remarked, that soil and climate make very great difference in quality.—T. G., *Clitheroe*.

#### PROTECTING TREES FROM HARES AND RABBITS.

IN reply to "R. F.," in No. 198, I beg to state, that during the progress of alterations at this place last spring, a great number of rabbits and a few hares found their way into these grounds, and notwithstanding trapping and other means being resorted to to destroy them, they have remained in possession (more or less), up to the present time. In the meanwhile they have destroyed a quantity of Berberis Wallichiana, variegated Hollies, variegated Savin, &c., as well as commenced to gnaw the bark of some Conifers until we dressed the stems with a mixture of night soil and soot, which has proved so far not to their palate. Mahonia (Berberis) aquifolium and fascicularis, and Berberis Darwinii have not been touched, whilst the others in close proximity have been eaten to the ground.—J. PRODGER, *Gardener to E. E. Peel, Esq., Brynnypps, Ruabon, North Wales*.

#### COTTON SEEDS SOWING.

IN answer to my notice stating I had some Cotton seed to give away, I have received more applications than I can comply with for a few days, but after that time I shall be able to supply each of the applicants in ample time.

Several correspondents have requested me to write to them, but I cannot do so, as it would entail more labour upon me than my engagements will permit. For the benefit of all wishing to raise and cultivate Cotton-plants, I will now state the little information I possess.

The seed should be sown in good new soil, covering the seed with it about half an inch. I cover mine with Sphagnum palustre, or grey Bog Moss, but mine are only sown for the purpose of testing the quality. I sow fifty from each packet sent to me, taking them without sorting, and then report how many germinate from the seventh to the twelfth day after they are sown. This enables the Cotton Supply Association to tell which seed offered to them is really worth buying. I then throw the plants away.

The seed readily germinates in a temperature of about 70°, and if intended for growing up to blooming, the plants should be kept pretty close to the glass, and have plenty of air without being subjected to cold draughts, and if they are kept steadily growing with nothing to overshadow them they will bloom at the back of the house.

I have flowered them, but never induced them to produce their cotton. I believe those who have plenty of room and time can ripen their seed, and, of course, have their pods of cotton.—JOHN HAGUE, 36, *Mount Street, Ashton-under-Lyne*.

ROYAL HORTICULTURAL SOCIETY.—Saturday last being the day appointed for the Early Tulip Show, we went to South Kensington, but found none but a few from the Society's

own garden. Major Trevor Clarke sent a small plant of *Chrysanthemum Prince Albert* in good bloom for this late period of the season. Except the remains of the previous weeks' shows this was the only plant of any kind exhibited.

#### A NOVEL FEAT IN GRAPE-GROWING.

**PROPOSITION.**—Given in January an eye of a Grape Vine; to propagate from it, and cultivate a plant capable of bearing three or four well-shaped bunches of Grapes averaging three-quarters of a pound, berries well swelled, nicely coloured, and richly flavoured, for the decoration of the Christmas dinner-table the same year.

I saw this beautifully accomplished at Coombe Abbey in 1863. Perhaps Mr. Miller will kindly enlighten us by stating his mode of operation.—P. M.

#### THE ARBORETUM—DECIDUOUS TREES.

In a recent Number, at page 23, Mr. Robson has touched upon a subject which must yield to none in importance in whatever point of view we regard it. In the article, "Arboretum *versus* Pinetum," the fact that arboriculture either has been and is neglected, or is at the present time confined to only a branch of it is fully brought out, and in calling public attention to it, Mr. Robson has rendered another service to the cause of horticulture.

Not presuming to sufficient knowledge and experience to act as "counsel for plaintiff," I am content, if it is permitted to me, to appear as a witness in the plaintiff's interest.

It is long since I had in mind to direct attention to the circumstance, that while California, British Columbia, Japan, and other distant regions were found to be rich in the most beautiful and attractive, and probably many of the most useful of the Coniferous tribe, not a single addition worth mentioning had been brought thence to our deciduous trees; not that those countries produced none, for there appears no evidence to that effect, or those countries would be exceptions to the general rule, that the finest and most valuable deciduous trees which are found in the north temperate zone of both hemispheres. But it is far more probable that the collectors whose labours have extended to these distant parts have altogether neglected the deciduous trees, and that, too, under the influence of causes which have long existed—*viz.*, the planting and formation of arboreta in which indigenous and exotic deciduous trees have the prominence due to their value, beauty, and numerical proportion has been for many years in abeyance or out of public favour. Thus many specimens of exotic species already introduced and existing in England are so seldom seen, or are so few in number, that their beauty and utility are not appreciated; and, therefore, not being sought after, no thought is taken of them, or to add to their number by propagation or further introductions. It is time that such a state of things should cease, for it does, as Mr. Robson says, little honour to our discernment; and now that the subject has been fairly broached, a discussion of it may not be without good results.

What ordinary pen can adequately express the glory of the forest trees, or describe their beauty, their majesty, nay, their grandeur? They are the men of the vegetable creation, and as such claim all the honour due to majesty and strength. Nor is it altogether necessary to descant too much in praise of things simply as they seem in the columns of a Journal, where the main object is rather a sober discussion of useful truths, and to elicit facts of utility whether they be to afford innocent pleasure or to contribute to an economic purpose. In either case trees stand out prominently for notice. Their size, form, diversity of foliage, and in many cases the beautiful flowers with which they are in one or other season of the year adorned, are all points affording the highest gratification, and must strike the most careless observer even; while the solid comforts we derive from their fruit, timber, bark, gum, resin, and other products are too obvious to require enumeration. Such being among the conspicuous characteristics of trees, ought we to rest satisfied with what we possess? And while the remotest regions of the earth

are searched to add new charms to our greenhouses, conservatories, and flower gardens, can no addition be made to our parks and woodlands?

These inquiries have been only partially responded to—that is, we have received numerous additions to our hardy trees, but all of similar character. At the same time these additions bear striking evidence of the enterprise and courage that has been the means of enriching our land with them, for there is no region in the north or south temperate zones, or mountain district in Europe, Asia, Africa, or America, that has not supplied fresh varieties of the Coniferae, as the numerous Pinetums amply testify.

Though striving to awaken interest and immediate action in the work we have before us—and in this *we* I solicit permission to include all true, zealous, and enlightened friends of horticulture—let us not depreciate the stately symmetrical Conifer; let us give it all the consideration it deserves; let us fully acknowledge its ornamental qualities, and avail ourselves of its utility; but let it not monopolise our whole thought in its relation to arboriculture; let it have its share, and full share; for how could we dispense with the least jot of marvellous beauty that is brought to our view in the lovely forms we now possess, reminding us of distant scenery (but faintly, perhaps), which few, very few of us can ever hope to see, and still more of the wondrous works of Him who made all things? But for the argument, or rather hypothesis induced in the article above referred to. If the most distant countries of the world can furnish so many additions to the pinetum, are there not deciduous trees there in a similar proportion as in other countries, and equally varied in character, and which can give increased variety to our own species, and add new charms to our woodland scenery? Let us hope that the noble enterprise that has accomplished the one may achieve the other, and that speedily.

It is but too true that the introduction of fresh kinds of deciduous trees has been grievously overlooked. It is rather commonplace to ask how a park would look with all Conifers, or even with a majority of them. It is too well known how monotonous is the sight of a Fir or Pine plantation, and that no comparison can be made between such and a natural wood. Nor is it difficult to find a reason why exotic deciduous trees have not been more extensively planted of late years. Nurserymen will not be at the pains to propagate what they cannot sell; proprietors cannot plant what cannot be obtained; but we are taught by one of the simplest rules of political economy that if the demand is increased the supply will follow. A knowledge of the existence of useful and ornamental deciduous trees must be made known, and a sense of their value entertained, then we may hope to see the desired object attained. The great work of Loudon remains upon the shelves year after year, unconsulted and unthought of, and it must therefore become one of the duties of gardening periodicals to spread abroad this knowledge.

It is not my purpose to investigate minutely the causes that have led to the neglect of the more extensive planting of deciduous trees. Ignorance on the part of botanists and those who pursue botany as an intellectual amusement is certainly not one of them. Before briefly stating the arrangement of detail with which I propose to follow up this article, I cannot forbear quoting the beautiful lines of the poet.

"No tree in all the grove but has its charms,  
Though each its hue peculiar; paler some,  
And of a wannish grey; the Willow such,  
And Poplar, that with silver lines his leaf;  
And Ash, far stretching his umbrageous arm,  
Of deeper green the Elm, and deeper still,  
Lord of the woods, the long surviving Oak.  
Some glossy leav'd, and shining in the sun  
The Maple, and the Beech of oily nuts  
Prolific, and the Lime at dewy eve,  
Diffusing odours; nor unnotic'd pass  
The Sycamore, capricious in attire,  
Now green, now tawny, and, ere autumn yet  
Hath chang'd the woods, in scarlet honours bright."

No further argument need be adduced in favour of the restoration of arboriculture to its legitimate rank, and a healthy and vigorous existence. There is, or was, an arboricultural committee of the Royal Horticultural Society. What are they doing? What have they done?

The particulars with which it is proposed to follow this article will comprise an account of many of the exotic deci-

duous trees that have already been introduced into Britain, and of others known to exist in their native woods. This account must necessarily be concise, but it is intended to point out the most conspicuous features of each species, and to mention its utility as far as known. The list will doubtless not be without omissions, and may contain inaccuracies, which shall be open to correspondents to supply and correct, it being understood that such will be thankfully accepted. The information has been compiled from trustworthy sources, and having in past years made a collection of leaves of all the exotic deciduous trees that I have met with, these will in every instance be examined when penning the notes. Indigenous kinds, grand and equalling, as they do, all foreign species, will therefore be omitted, or if named, only passing alluded to.—ADOLPHUS H. KENT, *Blechnigley*.

(To be continued.)

## MORETON HALL,

THE RESIDENCE OF GEORGE HOLLAND ACKERS, ESQ.

MORETON HALL, situate at a distance of about three miles from the town of Congleton to the south-west, the princely residence of George Holland Ackers, Esq., R.N., is a mansion of some pretensions, built in the castellated style, presenting a noble exterior, and its interior accommodation is most ample. There is a banqueting-room 36 feet wide, 70 feet long, and proportionably lofty; adjoining this is the dining-room, 54 feet long, entered by folding-doors of large dimensions; and ranging with these is the saloon about the same size, likewise having folding-doors. The three when thrown open form one immense room, producing a magnificent effect. This mansion was built to supersede a fine baronial hall, such as there are but some solitary instances remaining; its external is composed of timber painted black, and the intermediate portions whitewashed, the novelty of the sight and cleanly aspect attracting the notice and admiration of travellers; the only drawback is its being near the main road and in a low situation. The residence stands about a mile and a half from the Mow Cop station on the North Stafford Railway, and about three miles from the summit of Mow Cop—a place famous for pic-nic parties during the summer season—the altitude of which is 1091 feet above the sea level; it is surmounted by its old tower, and an isolated rock called "The Old Man of Mow." The mansion and gardens are situated in a beautiful park, the principal entrance being on the north side leading from the road from Congleton to Newcastle, the other commencing at the eastern extremity of the park nearer the gardens. The latter being the way by which I entered, I passed by a handsome Gothic lodge through two large iron gates, opened by machinery from the interior of the lodge; these gates were supported by two massive stone piers. The gardens may be about a quarter of a mile from the east lodge, and, perhaps a little more than a mile from the north entrance, and after passing through a shrubbery, which obscured the garden walls from view, we came to the back part of the gardens, where there is that indispensable part of a large establishment, called the frame-ground.

In the frames there were large quantities of fine healthy Cinerarias, in almost endless varieties, for greenhouse decoration. Strawberries in pots were placed under spare lights for early forcing to protect them from heavy rains, which are very frequent in this climate in the autumn, and also to assist in ripening the crowns and perfecting the embryo fruit. On a bed of coal ashes was a fine collection of Chrysanthemums, with dark green leaves hanging over the sides of the pots. Close at hand was a large quantity of cuttings of various sorts of bedding Geraniums being struck in the open air, without any covering of glass, just in the same way as I have seen the bulk of the bedding Geraniums propagated at the Crystal Palace, and the same as the late Mr. Beaton used to advocate in the pages of this Journal. Propagated thus there is less trouble keeping them through the winter than when coddled in heat, and they turn out more robust and vigorous in the spring. Along the back wall of the kitchen garden was a Mushroom-house, from which a succession of Mushrooms is obtained all the year round.

We now pass through a door into the kitchen garden, surrounded by high walls. It covers about two acres, and

there would be about another acre of kitchen-garden ground outside the walls. Near the entrance was a range of span-roofed houses running east and west, and divided into four compartments. The first was devoted to such plants as Azaleas, the retarding of Achimenes, &c.; the second contained fine specimens of *Lilium lancifolium*, Fuchsias, &c.; and the third was a cool fernery; but to enumerate all the beautiful plants it contained would simply be to recapitulate the lists published in a respectable nurseryman's catalogue; suffice it to say that all the plants were in perfect health. The fourth compartment was a useful propagating-house.

In close proximity to these houses was another range in two compartments, which were north and south. The east side of the first house was devoted to winter Cucumbers and very late Melons. The Melons are planted at each end, and the Cucumbers in the centre, both are trained to the trellis near the glass. When the Melons were cut the plants would be removed for the elongation of the Cucumbers. The varieties of Melons grown were Trentham Hybrid and Mounsdens' Moreton Hall, the latter a variety raised by Mr. Mounsdens, the intelligent head gardener. On the opposite side of the house was a good selection of stove and greenhouse Ferns and Lycopodiums. On the roof was a large plant of *Allamanda Schottii*, but it had not cheered its admirers this season with its golden flowers, probably owing to its being turned out of a pot into the open bed in the early spring, which caused it to run too much to foliage instead of bloom. In the next house was a collection of stove plants. There were good specimens of *Gloxinias* both of the erect and drooping varieties, *Begonias*, fine *Cockscombs* 2 feet across, fine-foliaged *Caladiums*, a very good plant trained balloon-shape of *Hoya bella*, and *Cyrtoceras reflexum* covered with its beautiful racemes of white flowers. Under bell-glasses were *Cephalotus follicularis*, the pretty little Pitcher-plant, and from the roof was gracefully suspended the fragrant *Stephanotis floribunda*.

Passing out of these houses we entered two Peach-houses, each 60 feet long; they are furnished with neat narrow paths in the centre, and are 7 feet wide; the back wall and front glass is 12 feet high, the apex may be 12 or 15 inches higher, and air is given by means of machinery. The front sashes open behind each other, running on wheels in a groove. The front of the houses and back wall are planted with Peach and Nectarine trees; the trees at back are trained to the wall, and those in front to a trellis about 15 inches from the glass. The front trees are allowed to grow about 5 feet high. At intervals of about 15 feet or between each tree are Vines planted at back and front, and trained to an arch underneath the roof, from which were suspended some splendid bunches of Grapes. What with the luxuriant Vines that shaded the pathway, the fruit suspended from the roof and hanging on either side in such beautiful clusters, and the delightful odour exhaled by the ripe Peaches on the wall, these houses were at the time of my visit (September), a delightful promenade. Next in order was an early vinery, in which fruit was still hanging. The Vines are planted in front of the house about 2 feet apart. This plan is an advance on planting one Vine under each rafter at about the distance of 4 feet; for the same number of bunches can be taken from the roof of a house, and only half the number from each Vine, and, as a consequence, the individual bunches must be much finer.

Stepping out of this house I rambled round the kitchen garden. My attention was arrested by the fruitful condition and peculiar mode of training of many of the goblet-shaped Apple and Pear trees. This style of training seems a prominent feature at this place, and the quantities of fruit would be great and fine in quality. On the west wall were some very fine Plums, and the wall with a north aspect was covered with Morello Cherries extremely fine, and covered with two thicknesses of netting to protect them from the depredations of the feathered tribe. Glancing on to the different quarters I observed large beds of winter vegetables, such as Borecole, Brussels Sprouts, &c., and from their vigorous growth and the dark green hue of their foliage they exhibited little evidence of the previous drought.

We now pass through a door at the west end of the kitchen garden, which brings us in the direction of the mansion. A

large mound of earth thrown up a considerable height and covered with Rhododendrons, entirely hides the kitchen garden from the mansion and the principal parts of the pleasure grounds. The wall is flanked with a broad ribbon-border, and beginning at the back there were four or five rows of Red Beet, next yellow Calceolaria, then Geranium Tom Thumb, the next row Lobelia speciosa, finishing in front with a broad band of Cerastium tomentosum. We now pass through a short tunnel underneath the above-mentioned mound. To the right, at the east end of the mansion, are the stables, carriage-houses, yard, &c., but all judiciously screened from the view of the visitor. To the left was the ice-tower. Passing through a door we come to a broad terrace-walk on the south side of the mansion. This walk was about 540 feet long, and 60 feet wide. The carriage entrance is on the north side through a lofty portico, beneath which there is ample space for a carriage and four horses to pass. The mansion, I should have before stated, is nearly 300 feet wide, and I very much regret the inability of my humble pen to do justice to its ample proportions. From the centre of the terrace-walk on the south side of the mansion, a gravel walk 12 feet wide runs down the pleasure ground. At each angle stand fine specimens of Araucaria imbricata. As I passed down the walk I noticed to the left the geometric flower garden, but when I took into consideration the extent of the pleasure grounds, the beauty of the terrace and other walks, and the princely grandeur of the mansion, I thought the flower garden far too small. The beds were nicely planted, and the flowers were extremely gay. The centre and four corner beds were planted chiefly with Asters, and although I never saw such a grand collection of that beautiful flower, nor so well grown, I thought them out of place in the flower garden in such large masses. Proceeding down the centre walk I came to a wooden bridge which spans the lake, a fine sheet of water, though rather narrow where the bridge is fixed. Near this place were some fine deciduous trees which must make this a charming retreat during the hot days of summer.

Bending our steps onwards through an interesting shrubbery, we bear to the right on a path which brings us to the western boundary of the pleasure grounds; a broad terrace walk forms the southern extremity. On the lower side of the walk is a low wall covered with Ivy, on the upper side a bank of earth extending the whole length and entirely concealing the walk and wall from the mansion and the upper part of the ground. At each end of this terrace walk, upwards of 600 feet in length, is a bastion that gives a kind of finish to the walk.

I must now take my leave of Moreton. Before we had got all over the pleasure ground the shades of evening set in, I felt satisfied with what I had seen, and derived from it much information and profit; indeed, any gardener may be benefited by visiting the neighbouring gardens and noticing the errors or progress in the labours of others. I thought we might go long expensive journeys from home expecting to see variety and novelty, while everything we wish for may be found in our own immediate neighbourhood. I may say in conclusion that every part of this extensive demesne was in first-class keeping, and reflected great credit on the ability of Mr. Mounsdon, the respected gardener, who with the utmost courtesy was anxious to point out every part of the gardening establishment worthy of notice.—QUINTIN READ, *Biddulph*.

#### GLAZING WITHOUT PUTTY.

In compliance with your request for information respecting the above mode of glazing, I have to state that I saw one greenhouse so glazed in the neighbourhood of Boston, U.S. It had a neat clean appearance, and was most favourably reported of as a secure house. My informant stated that the glazing was not so liable to be injuriously influenced by the weather as when done with putty, which one can readily believe, as most of the leaks in our houses are caused by defects in the putty or puttying.

The way in which the house alluded to was glazed was this—after the priming coat the glass was laid on in the usual way, but without bedding; the panes were securely pegged in, and then three or four coats of white lead given, which proved quite capable of resisting the great extremes

of heat and cold in that country, and I should imagine would prove fully as efficient in this. At all events it would be worth trying whether putty cannot be dispensed with, for it is a source of annoyance in more ways than one. I should think that if the glass were laid in a fresh coat of white lead, and three coats over it, it would be still more secure than the above mode.

I have heard that white zinc is a better paint for out-door work than white lead. Can you, or any of your readers, confirm the report?—J. K., *Arch Hall Gardens*.

#### POTATO PRODUCE.

I NEVER for a moment thought of imputing anything to "AGRICOLA," "W. W. H.," and "UPWARDS AND ONWARDS," nor did I desire to lessen the value of their experiments. On the contrary, I read them with great interest and profit, as many of your readers have, no doubt, likewise done; but I objected (and I see no reason to vary in that respect, even after the temperate reply of "AGRICOLA"), to the produce per acre being calculated by the quantity of seed set. I do not think that seed Potatoes are of a uniform size, nor that 14 lbs. of sets of a Round Potato would plant the same ground as 14 lbs. of Kidneys, or another kind. From experience I have found sets vary much; there being no more than sixty in some cases in 14 lbs. of sets, whilst in others there may be as many as eighty-seven, and in one case ninety-seven, and these selected sets.

I think, therefore, that to calculate the produce by a given quantity of sets, varying in number so much as they do in different varieties, is apt to lead to an incorrect conclusion, for it follows that 14 lbs. of sets of a small sample will plant half as much more ground as those of a larger size of a finer sample—that is, presuming them to be planted at equal distances.

It is, I think, well known that one kind of Potato will plant half as much more ground than some other varieties, simply because the Potatoes themselves vary in size, the sets being large or small in proportion to the sort. How, then, can the produce per acre be calculated when it is not known what ground they occupy? They might all occupy an equal amount of ground, but of that we have no proof, and if one occupies more ground than another, that one has an undue advantage over the other.

Irespective of the unequal number of sets in a given quantity by weight, the distance they are planted apart also makes a wide difference in the calculation. "Ordinary distance," writes "AGRICOLA," "with the rows 3 feet apart." We are left to guess what ordinary distance signifies. In some localities Potatoes are planted in rows 2 feet 3 inches apart, 2 feet 6 inches, a very common distance, 3 feet in some cases, but this is rare amongst Potato-growers, and occasionally 3 feet 6 inches; as for distance in the rows, some plant at 1 foot, others at 15 inches, some at 18 inches, others at 20 inches.

"UPWARDS AND ONWARDS" does not relieve my doubts on this head. He plants in rows 42 inches apart, and from 15 to 20 inches apart in the rows. Here again a difference of 5 inches will tell immensely in calculating the produce per acre from a small quantity planted. I can assure the last-named correspondent that I do care to bear in memory what he writes, and am much interested and benefited by perusing his occasional papers in this Journal. His notices of distance and of ground occupied are certainly given in some of his articles, "sufficient to suit the customs of most localities," by which I presume sufficient is written for practical purposes. That I readily admit; but viewing them as experiments I think they lose much of their value through the omission of important particulars which he is so particular in recording with reference to some varieties—viz., the ground occupied, the size of the sets, and their distance apart. "AGRICOLA" writes, he "had credible information of a still higher result than that obtained by 'W. W. H.' and Mr. Lupton." Perhaps he will state when, where, and by whom.

"UPWARDS AND ONWARDS" claims a greater yield per acre for his root of Negro than that of Mr. Lupton's two roots. His occupied a square yard, those of Mr. Lupton 4 feet on the side, or 16 square feet, and yet his is the

heaviest (or equal) produce per acre. Mr. Lupton's sets were of average size. They did not spread so much, as they were strong.

I most cordially agree with the concluding sentence of "AGRICOLA"—viz., "that the free discussion of this and similar topics is not an unimportant step towards further progress," and I can assure him that I had no other object in view than to further that result as much as possible.

We have yet to learn many things in Potato culture—viz., the distance at which they can be most profitably planted, the kinds most suitable for different soils, the most desirable kinds for eating and also for productiveness, the most beneficial manures, and the most approved method of growing this

crop. All this can only be secured by instituting a set of experiments in different localities, each person planting an equal number, an equal weight, and an equal quantity of ground. We have clubs of all sorts, and I think none would be more useful than a "Potato Club," such as was proposed some time ago by Colonel Newman, Hillside, Cheltenham. Their experiments and experience would form a very interesting and valuable, because reliable, report, and the annual dinner would be all that could be desired, each exhibitor being obliged to exhibit his dish not only fit for table but fit to eat. All the members present would be judges, the winner obtaining his laurels by the votes of the majority. —G. ABBEY.

### AURICULA CULTURE.

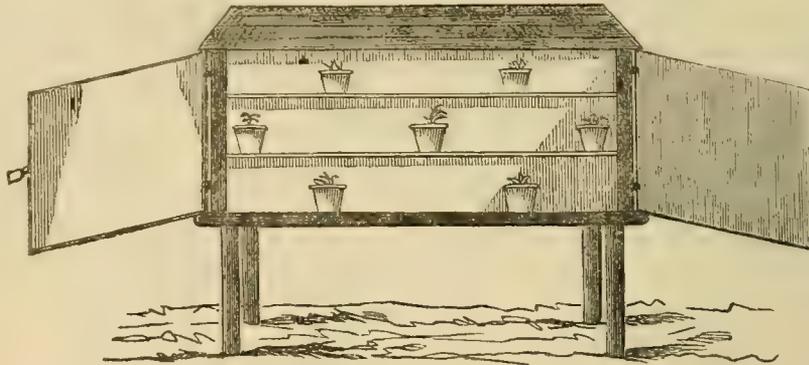

A ONCE very popular plant, though it has lost very many of its old supporters, is, I am pleased to see, likely to again become a more general favourite, though I regret to say that it is very questionable whether many of the best old sorts are not entirely lost. Though I cannot assist in obtaining those old favourites I will give a few short notes upon their culture generally, as they may be of use to amateurs and others not well informed upon the subject.

The plants having done flowering, about the beginning of May place them on slates in the open air, or, what is better, in an Auricula-frame, to which I intend referring before

concluding. They should be placed in such a position as will admit of the morning sun shining full upon them until about nine o'clock, but the situation to be a shady one during the remainder of the day. Carefully keep them clear of all dead leaves. These when they decay should be removed, taking every precaution, by the use of both hands, not to tear

or otherwise injure the plant in taking away any leaf which may not be ripened at the base. Such seeming trifles can not be too strictly enforced in the culture of good varieties of this plant. In dry weather water with moderate freedom, being careful that each plant has its drainage perfect. About the first week in June remove them into their summer quarters, which should be a shady situation in a cool place, where the air can have tolerably free access to them, still continuing to give them waterings when required.

About the second week in August prepare to pot them. Stimulating composts, though successful for a season, are very detrimental to lasting vigour in plants of this tribe, and are indeed the primary cause of early decay. The compost I advise is one part of good loam (yellow) obtained from thoroughly decayed turf, one part of thoroughly decomposed leaf mould (unless the turves from which the loam had been obtained were very thin, for if so the decayed herbage will be sufficient, and leaf mould may be dispensed with), one part decayed frame-dung, or one part cowdung which has been laid by and kept moist for a lengthened time, the latter is preferable. Add to these a fourth part of silver sand, and, where obtainable, a liberal dash of river sand—siftings of small grain well washed. Where this latter is not to be had a few potsherds broken small will answer instead. Previous to mixing these ingredients together let them dry if necessary, for unless they are all moderately so it will be exceedingly difficult to thoroughly incorporate them. The compost prepared, well cleaned and effectively crocked pots will be necessary. The crocks should take up as little room at the bottom of the pots as possible consistent with an efficient drainage.

If the plants are young, or offsets, turn them out of the pots, and carefully pick out from amongst the roots some of the older soil. Give them a moderate shift, and press the soil firmly around the old ball. Should the plants be old shake away most of the old soil, and having carefully pruned and cut away all dead roots, &c., repot them in moderate-sized pots. In doing so care should be taken to properly divide the roots from each other, shaking the soil nicely between and around them, and keeping the crown well up. Having given them a good watering, they should be again placed in a shady sheltered situation, until, having made

fresh roots, they are re-established in their pots.

I give a sketch of an Auricula-frame which I have found very serviceable in the culture of these plants, and into which I would place them when potted, and indeed this should be their general abode, as this mode of protection and shelter is preferable to frames having air-bricks back and front, sashes,

&c. The Auricula-frame, as will be seen, is very simple in its construction, four main posts as legs upon which to support the whole being the first requisites. A division runs through the whole length, thus forming a north and south aspect for the plants when properly placed. On either of those sides shelves are placed, on which are put the plants in pots. The north side will be found a nice cool place for them in summer, and they will be protected alike from very severe storms, insects, &c.; whilst the south is admirably adapted for them in winter, giving them what is so essential—an atmosphere entirely devoid of the damp at all times contained in glass pits, &c., in winter; besides, every opportunity can be taken of admitting the sun's rays when wanted the most. In this position, too, the stock can be flowered and tended in comfort. It will be readily perceived that the middle partition will be a great assistance to either of the ends we have in view, as the empty space on the north side when the plants are on the opposite shelves in winter, will assist materially, the shutters are being closed, in keeping out the frost; whilst the empty space on the southern side will, in summer, aid materially in keeping the other cool. By simply constructed hinges the roof of either side may be turned over upon the other, thus giving the plants the benefit of a free admission of air when needed, though I would, if constructing another frame, have the roof of glass. The shutters, made to take off and on, may also by a little contrivance, be made the means of breaking too strong a wind, as may be needed.

The propagation of these plants is effected by taking from the old plants offsets sufficiently large to form a cutting.

These should be taken off the plants in May, or as soon as the plants have done flowering, placing them under a hand-glass in a compost similar to that recommended for potting, with, however, in addition, a double quantity of loam. When rooted they are to be potted and treated as advised above. When offsets of any particular variety desired to be propagated cannot be obtained in May, a few may be taken off and struck in August, when the old plants are potted. Great care should, however, be taken that the plants be not too much injured, as wounds upon them at this season are very susceptible of damp, and are, consequently, apt to end in the rot, so much so, indeed, that I would not advise any to attempt the operation who can put it off for a season.

In saving seeds great attention should be paid to selecting good sorts only; by a judicious use of the alpine varieties impregnated with some of our best old sorts, much may yet be done with these quaint plants. No variation in the treatment of the plants is necessary for saving seed. The latter must be watched that it may be secured when ripe.

There are two ways of sowing. The seeds sown about the middle of August in boxes or pans of light earth, generally remain till the spring before germinating, and then come up much earlier than those sown in the spring, and are much stronger and sooner ready for potting. Seedlings are, however, readily raised by keeping the seeds in the pod until February, when they may be sown as above, and placed in a moderately-heated frame, to be potted off when sufficiently large to handle.

In conclusion, taking into consideration the position in which the Auricula grows naturally, the hill sides and mountains of southern Europe, and Switzerland especially, where during the whole of the colder winter months it is covered with a thick coat of snow, we are in possession of the facts that it likes a cool, moist, even temperature, with but moderate light in winter, a perfect drainage—as the hillside position shows—with a free supply of light and moisture, when the return of spring reinvigorates them.

When the plants are perfecting their blooms, care should be taken that wet or damp of any kind does not frequently rest upon them in dull weather.—W. EARLEY, *Digswell*.

### THE CLIMBING DEVONIENSIS ROSE.

I HAVE to thank "D., Deal," in his valuable and interesting article on new Roses, for so kindly mentioning my name in connection with the climbing Devoniensis. Though I have had the pleasure of introducing to the public this truly noble climber, I must disclaim the credit of having fixed the sport. I met with it in the west of England, and imagine its origin to be accidental. Apprehending its probable merits as a climbing Rose I bought what I could of it, and have been proving and, I trust, improving it for the last two years in the rosery here, so that I can now with confidence recommend it as the finest light climbing Rose in cultivation.

From its strong growth of one-year-old wood it will be found a most abundant and early bloomer. My pillar specimens in the open air were so beautiful in the spring that they half-verified dear old Dr. Watts—

"How fair is the Rose, what a beautiful flower!  
The glory of April and May!"

for towards the end of May the pillars were clothed with large flowers from top to bottom. Owing to this same vigorous growth its flowers in the autumn are not so numerous, though in this respect I am improving it, and have had many hundreds of fine blooms this year as late as November. When more known and more grown it will, I believe, take precedence of all its fair rivals in the ranks of climbing Roses.—HENRY CURTIS, *Torquay*.

EARLY KING POTATO.—I cannot answer your correspondent of last week, about the Early King. I never grew it, but it is a seedling from the Fluke, and I know it well by sight. "R. H." calls it "a round Potato," but in respect to form, when taken from the soil, it must be judged of as the chameleon is for colour.—UPWARDS AND ONWARDS.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE state of the weather prevents much being done in the open garden. *Asparagus*, if a constant succession is required, a bed should be made every fortnight till the end of March, a slight heat only is necessary. Keep the frames close and cover up well till the shoots make their appearance, when they should have light and air. *Capsicum*, seeds of the various sorts should now be sown in pots, which should be placed in a hotbed. *Cucumbers*, if a seed-bed is made and the dung was previously well prepared, it will be ready to receive the seeds after having stood a few days to let the rank steam pass off; a layer of light sifted soil may then be placed on the surface to the depth of 3 or 4 inches, sow the seed in shallow pans or in pots half filled with leaf mould. After sowing lay a piece of glass on the top of the pan or pot to prevent mice getting at them. *Kidney Beans*, a crop now sown in small pots, and when of a sufficient size planted in a large pit where there is a command of heat, will produce more abundantly than those in pots. The introduction of the red spider into the forcing-house will also be avoided by adopting this plan. *Mushrooms*, beds for early crops should now be made. The horse-droppings must be previously well worked to prevent them from attaining a burning heat. Keep the dung well beaten down at the time of making. *Potatoes*, if it is not convenient to prepare beds for them immediately, plant some in small pots and place them in any corner of the forcing-house, where they can remain until they have made their appearance above ground. They should then be planted out or be placed in a situation where they can receive a sufficiency of light.

### FRUIT GARDEN.

Where the means are at command, we would recommend Peach and Nectarine trees to be dressed with the following composition, as well as washing the walls against which they are growing. Scotch snuff, fresh slaked lime, and sulphur vivum, of each 1 lb., mix with soapsuds to the consistence of paint, add sufficient soot to make it of a grey colour, and lay on with small paint-brushes.

### FLOWER GARDEN.

The planting of large shrubberies on lawns is one of the principal obstacles in the way of beautiful specimens of shrubs, as many choice specimens are planted in them, which in a short time are hidden or killed by the luxuriant-growing sorts. If they are not completely killed they are but skeletons of what they ought to be. To obviate this and still retain the feature of a shrubbery, we would recommend them to be planted singly on the grass at such a distance from each other as to allow of their showing their proper character. A hole may be dug and suitable soil put in for each plant if necessary. The turf should then be laid down nearly close to them, leaving only a small circle round each. Thus effect may be given without disturbing the roots by digging or crowding the shrubs so much as to mar the beauty of each individual species.

### GREENHOUSE AND CONSERVATORY.

The continuance of wintry weather will not allow of any essential variation of treatment here. The precautions previously recommended in regard to the necessity of allowing exterior influences to govern, in a measure, the temperature within the houses must be insisted on. Should high winds prevail, little air need be admitted. Few of our glass houses are so constructed as totally to exclude air; aided by the pressure of strong currents it will be insinuated through every crack and crevice, and the necessity of admitting it by other means obviated, at the same time more fire heat is required to preserve the requisite temperature of 50°, which is ample, while the thermometer indicates so low a degree of cold outside. *Cinerarias* and *Calceolarias* will require a liberal supply of water, and, possibly, increased pot room. *Pelargoniums* to be cautiously encouraged to activity. The mould intended for greenhouse plants should be prepared and sweetened by several turnings, and a sufficient supply for immediate use should be stored in an open shed. In the conservatory, *Kennedias*, &c., will be showing bloom, and what training they require should be done at once, but the pruning of these should not take place until after blooming. When Orange trees are grown to decorate the flower garden is

summer, care should be taken to prevent their beginning to grow previous to their removal to the open air, and more especially if the trees are wintered in a dark-roofed house. Turn all greenhouse plants frequently to prevent them growing one-sided, and see that no decayed leaves are allowed to remain on them.

#### STOVE.

Give as little moisture here as possible, and do not aim at high temperature, the colour and durability of flowers will show how injurious both are in excess at this period. When such plants as *Aphelandras*, *Justicias*, *Poinsettias*, and other winter-flowering sorts have done blooming they should be removed to a drier atmosphere, and water gradually withheld to effect the proper ripening of their wood. With stove climbers not required to bloom before the autumn, pruning may be deferred for some time yet, which for an earlier show should be done at once. *Passion-Flowers*, *Bignonias*, and similar plants, which make long annual shoots, should only have the wood thinned, and slightly shortened, while some others, as *Combretum*, *Beaumontia*, &c., may be spurred-in. This depends on the space allowed for their growth. A portion of the stock of *Achimenes*, *Gesneras*, and *Gloxinias*, may now be potted in light mould, and placed in gentle warmth. Some of the *Gesnera zebrina* which were first in flower, should soon be induced to rest for early work next autumn. This is easily done by withholding water, and keeping their foliage still exposed to the light. Such of the *Orchids* as are commencing growth, if very dry, may have a little water applied to the roots, this must be done cautiously. The best way is to apply it round the sides of the pot, and by no means to saturate the soil around the collar. Lose not a moment in exterminating insects.—W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

OUT-OF-DOOR work very much depended on the weather. Wheeled chiefly from rubbish-heap in frosty days and mornings. Collected a little more ice to make more sure. Trenched and turned over previously ridged ground, to give it the benefit of the pulverising effect of a good frost, and protected what needed protection; but Nature has given us the best of all protection in the shape of a good fall of snow, which, besides keeping things safe in the meantime, will help greatly when it melts to fill our pools and tanks for next season. For the mode of collecting snow instead of ice see a previous Number. In the Mushroom-house introduced more *Rhubarb* and *Sea-kale*, and a number of *Potatoes* in small pots, to fill the pots with roots before transplanting. Cleaned and examined Mushroom-beds, keeping the house cool, as we do not wish for a great supply just now. To make the most of a garden, and to allow the gardener to do the best with his productions, he ought to know of all changes as to company as soon or even sooner than the cook and the housekeeper. When gardeners are kept in the dark as to these matters, the possessors of gardens must expect a glut of rarities when they value them least, and a deficiency of them just when they would value them most.

Put up some beds for *Potatoes*, but the weather has prevented us planting them. Gave light and air, except on snowy days, to *Radishes*, *Lettuces*, and *Cauliflowers*. When cold and dull, and especially when snowing, the plants will sustain no injury if in darkness for several days and nights, instead of one night only. The great rule of safety in such cases is simply to make sure that the plants shut up are too cold to grow, for growing even by extension in such continued darkness would be ruinous.

We recollect being told of a case in point by the late Mr. Weeks, sen., the great mechanist, to whom we are chiefly indebted for most of the improvements in heating by hot water. In his younger days he had been a practical gardener, and about New-year's time he had a pit or frame of fine *Cucumbers*, we forget which now, but heated and banked up with fermenting material. Some neighbouring gardeners called on him on New-year's day, ostensibly to see him, but in reality to get "a wrinkle" about these *Cucumbers*. It was a very cold, frosty, snowy day, and the covering had been merely rolled down a little to let the visitors see the

inside. Some of them stared, and better stared, and winked at each other as they pointed to the covering, thinking that in this they had discovered the secret; and without asking a single question as to the covering, went home to cover their *Cucumber* plants into disease, insect harbours, and ultimate death. We think we can see the old worthy before us now as he chuckled and told the tale, always concluding with the observation, "You know I would have been too glad to tell them that such darkness in any amount of light was an exceptional case, only warranted by the peculiar circumstances; but as they were too proud to do anything but look, I also was proud enough to withhold any explanation, merely because it was not asked for." Amid the excitement of the present we are apt to forget the worthies and the original geniuses to whom we owe much. We thence learned the lesson never to refrain from politely making inquiry on all suitable occasions; and that, therefore, to walk round a garden and do nothing more than look, and thus find nothing on which to ground an inquiry or express admiration, is not the plan to give pleasure to the gardener visited, nor yet the means for gaining a personal advantage from the visit. As the result of some experience we confidently state that the smallest garden visited may well afford instruction, and in some cases even more than some palatial residences, where we are apt to be overwhelmed with the gorgeous and the brilliant. In no case will we be likely to gain much if we are too stolid to observe, or, like Mr. Weeks's visitors, merely look, and wink, and say nothing.

#### FRUIT GARDEN.

Looked over fruit-room. Moved *Strawberry* plants in bloom in the pit to the best part for light and air. Damped *Vines* in early house in sunny days; also gave a sprinkling in such days to the early *Peaches* to soften the paint of clay and sulphur in which the buds are encased. Those who have *Peaches* in bloom just now in this dull weather must use every means of getting the fruit set, such as giving them the advantage of every ray of light, and either dusting the pollen on the stigma by means of a camel-hair brush, or by using a flat thin board for quickly moving backwards and forwards near the trees in the way of a fan. This we consider far preferable in such dull shifty weather to making large fires so as to heat the house sufficiently to admit of great quantities of air.

*Air-giving* is a matter of much moment in all cases of early forcing, both as respects success and economy. There is not only the expense of firing during the day, to permit of free air-giving in severe cold weather, but there is the danger of having an extra heat in the heating medium increased by a sudden outburst of sun, and the two heats combining with a dry, cold, parching air rob the young growth of its moisture, and the evaporation is apt to become so great and rapid that the action of the roots is unable to supply it. In such changeable weather it is better to give only a little air at the top of the house early, and then to keep up no more artificial heat than will just keep all going on quietly, and then if the sun do come out a considerable rise from sun heat will have none of the bad effects which heat from artificial sources would entail, unless counterbalanced by this wasteful and dangerous free air-giving. Thus suppose in such weather as this, stormy and frosty, a house of *Peaches* setting and in bloom, we would be satisfied with from 50° to 55° at night. If the morning augured a dull cold day, we would put on a small fire, so as to raise the temperature to about 60°, with a very little air at the highest point of the roof, just to prevent stagnation in the atmosphere. If the morning promised a sunny day, then we would put on no fire, wait until the sun raised the heat to from 60° to 65°, then give a little air at the top, and only increase it when the heat from the sun rose above 75°. A close heat at that degree and upwards would be dangerous, but it would be relished from sun heat, and especially when a little air was previously given to prevent all danger of scorching or scalding, and thus the danger on cold days would be very much less than by admitting a great amount of cold frosty air. Of course when the temperature outside approaches what the inside temperature ought to be air may be given very freely. We only wish it to be clearly understood that for tender things, and in such changeable weather, it will be best every way only to give a little air at the right time—that is, early, and then to regulate the

temperature considerably by the heating medium, bearing in mind that the higher forms of vegetable life cannot healthily conduct their successive developments unless the heat they receive is proportioned to the light they enjoy.

In sunny days it is also important to shut up early in the afternoon, as the heat from the sun with its electrical action will be more valuable than a later free circulation of air, which from its very coldness would prevent the sun from exerting its salutary power. In thus shutting up early, say from two to three o'clock, two things must be guarded against—first, the not making the house too hot, even with sun heat enclosed, which is all the more particularly to be guarded against if the roof is close-glazed; and secondly, so to proportion the action of the fire heat that it would just begin to act as the heat from natural causes had descended to the point of safety. As to shutting up close at all, we merely allude to it as a matter of economy in fuel, which many of us must make a first consideration even now, after all the advantages from railways. But for that, in all close-glazed roofs we would rather have little openings at the ridge of the house continuously night and day. It is amazing how effective even half-inch openings in width are in preventing stagnation of air, or scalding or scorching, when it gets hot.

We recollect some years ago seeing a fine example of prudent forethought in a friend whose garden we visited in early spring. It had been a fine sunny day, though the air was cold behind the sun, and the houses where a high temperature had to be maintained, were shut up early. We entered a Cucumber-house early in the afternoon, and were forced at first to run out again, the heat was so excessive. By a mistake the valve connecting the Cucumber-house with a powerful boiler had been opened, and the pipes were near enough the boiling-point to prevent the hand touching them. At once the valve was reversed, the paths slushed with water, the beds and the leaves of the plants syringed, the latter on their under side, and small openings made for the escape of the heated air at the ridge. The man in charge, finding the mistake, was throwing open bottom and top ventilators with the greatest freedom; and we have no doubt if that course had been followed even for a short time, the sides of the best leaves would have been found scorched next day, while from the treatment adopted there was little or no damage done. In such a case it would have been quite time enough to have let the pipes get sensibly warm by four o'clock, and then increased the heat gradually as the sun heat lost its power.

What has been said above as to Peaches will also refer to Vines and other fruit trees. Early Vines with the bunches in bloom might as well be brushed over in a sunny hour, though for setting purposes nothing is better than drawing a dry hand gently along the bunch, so as to scatter the pollen, and relieve the top of the pistil of its cap-like hood in the shape of the calyx of the flower.

#### ORNAMENTAL GARDEN.

We have been considerably hindered with some ornamental planting, &c., owing to the frost and snow. That is of little consequence in a garden where the men can be easily changed, but it is often a very serious thing with those who contract for planting. Those engaged in planting for timber and cover got on pretty well except when the snow was in the way, as the holes could be made in frosty mornings and days, and the planting proceeded with when it was dry and fine; and the ground being just moist and not wet, the trees or plants were planted in first-rate condition. After very heavy snows or rains it would often be economy to wait a day or two until the ground had become more kindly, as neither a tree nor a Cabbage plant is likely to succeed any better when the mud and water keep spurting about the workman's shoes.

*Mahonia (Berberis) aquifolium.*—Allow us here to express our best thanks to those friends, and especially those personally unknown to us, who have given us their experience with this useful sub-evergreen. Most of these friends, however, leave the matter as to the plant being untouched with hares and rabbits somewhat in doubt. Perhaps the most important communication received is from a well-known gardener of great experience; but as we have not had time to consult him as to our using his name publicly, we will

here give part of his communication under the initials of "J. M." Our friend says:—

"About six years ago we commenced planting rather extensively for under-cover, and amongst other things used was a quantity of *Mahonia aquifolium*, chiefly planted at short intervals by the sides of the rides, the intention being to secure both utility and ornament. Contrary, however, to my expectation, they have been almost totally destroyed, and I noticed to-day, that where a single plant was to be found, the leaves were much nibbled, and left on the ground; but, as in your case, I consider the plants were rather small for thus planting in woods where rabbits abound. In another part of this estate, we planted three years ago a few large plants, all of which have done well, although there are plenty of rabbits to be found near them. My opinion is, that when *Mahonias* are to be planted for cover, plants of considerable size and strength should be used; for then although rabbits, &c., might nibble the outside leaves, they would not be so likely to cut the plants totally down. Of course, such larger plants would be higher in price, but then a less number would be required, and I believe the ultimate result would be more satisfactory. If this plan of larger plants is not adopted the rabbits, &c., should be kept down on the fresh-planted piece until the plants are established. After that the rabbits will soon become numerous enough, as soon as the plants are established. At any rate here, where rabbits, &c., are so numerous, I find it almost useless to plant any underwood when the plants are small and young. Dressing large quantities of such plants with any sort of mixture, is not only a very tedious work, but one which is seldom followed with sufficiently satisfactory results."

We have no doubt there is much in what our friend says, as to the size and strength of the plants; but then, on the other hand, young, stubby plants, if left alone, are apt to make fresh growth better than older stunted plants.

*Flower Seeds, Vegetable Seeds, &c.*—Took the opportunity of a snowy day, to get a few of these properly cleaned and put away ready for use. Unless labour is very abundant, or where there is a particular pleasure in attending to all these minutiae, as in the case of amateurs, there is little or no advantage in doing much of this sort of work in private gardens, as by the division of labour the regular seed growers and merchants can do it more economically and satisfactorily. Amongst the wonders of the age, is the price at which our leading seedsmen send out their seeds, so nicely done up, and the specific practical directions accompanying each packet, or in the catalogue which will generally accompany the order. "Live and let live," is not only philanthropic and benevolent, but it insures true thorough-paced economy. The saving of seeds should in general be chiefly confined to scarce and rare articles, or to superior varieties of some common plants, and for the pleasure of distributing them to those whose circumstances will not enable them to purchase, even at the cheapest rates. The saving of such seeds amongst cottagers too, leads to habits of carefulness and industry—great desirables among the children, altogether independent of the money-value of the seeds. "Can do is easily carried about." So it is, and a "Jack of all trades" is no doubt often a very clever fellow, a man who would take a first place as an emigrant in the back woods, and yet who may find it difficult to earn his bread in this land of competition and division of labour. Even the most pleasant and agreeable hobby and pursuit may be ridden too hard to be judged by the stern maxims of economy. We have frequently known first-rate mechanics, we might almost say artists, so fine and cunning was their workmanship, and so handsomely paid were they for their labour, who were so fond of their large gardens, that they would be doing something in them in the early morn and in the dewy eve, and thus securing the means for personal health and the gratification of their tastes, as well as imparting advantage every way to their family. All right and proper, but was it equally right and proper for such men, often at much loss to their employers, to take several days in the busy season to do the rough of the gardening work themselves, when even with all their energy they could not manage to do quite as much as the jobbing gardener, who would have been well pleased with half of the money which the mechanic would have earned at his usual avocation? In such cases it is not

all gold that glitters, and "a penny saved is not a penny gained," when the saving involves the loss of gaining two or three pence.

**Potting.**—Proceeded with shifting bedding plants, greenhouse plants, and stove plants as opportunities offered, and amongst the stove plants set some Caladiums, that had stood in a dryish warm corner with some damp moss over them, into a bed with some bottom heat just to start them into growth, when fresh potting can be given them. We have also potted a quantity of last year's *Fuchsias*, and in a different way from what we generally do, because it suited our circumstances as to room better. Generally we prune the plants, and let them break in the old pots before we remove part, at least, of the old soil, and put into fresh. In the present case it was an object that the pots should occupy as little room as possible, and therefore the plants were roughly pruned, turned out of the pots, and the old soil shaken from the roots; the soil being rather dry, the roots were then set for ten minutes or so in shallow warm water, about 70°, just to moisten them, and then allowed to drip before they were placed in light fresh soil and into much smaller pots, which were placed in a temperature not below 45°. When the pots are filled with roots the plants will get more pot-room. The heads will be damped from a syringe, especially in sunny days, but the soil will receive little water until the fresh young roots are working freely in it. Where very fine plants are wanted in bloom early, a little bottom heat will be a great advantage at first, and manure waterings as soon as the flowering pots are filled with roots.

In this dull weather a coolish temperature is the best security against weak growths and insects. Spare the coal heap, and you will be able to spare the tobacco smoke. —R. F.

COVENT GARDEN MARKET.—JANUARY 28.

In consequence of the severity of the weather supplies are short, but the demand at this season being far from brisk, quotations are nearly the same as last week. Forced Asparagus is hardly to be had; Apples are still plentiful; and dessert Pears consist of the same varieties as enumerated last week.

TRADE CATALOGUES RECEIVED.

Barr & Sugden, 12, King Street, Covent Garden, London. —Compendium of Illustrated Guides to the Flower and Kitchen Gardens.

Wheeler & Sons, Gloucester.—Wheeler's Little Book, or Select Seed List.

Edward Taylor, Malton.—Descriptive Priced List of Fruit, Forest, and Ornamental Trees, Shrubs, &c.; Catalogue of Agricultural, Kitchen Garden, and Flower Seeds.

Butler & McCulloch, Covent Garden, London.—Spring Catalogue of Seeds for the Kitchen Garden and Flower Garden. Austin & McAslan, 16, Buchanan Street, Glasgow.—Catalogue of Choice Vegetable and Flower Seeds.

R. Smith, Worcester.—Seed List; List of Plants of the Fir Tribe Suitable for the Climate of Great Britain.

TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

PANDANUS JAVANICUS VARIEGATUS AND STEPHANOTIS FLORIBUNDA CULTURE (J. L.).—If you have the convenience of a hotbed you may plunge them in it after potting them, or place them in an increased temperature in March, which is what, we presume, you mean by starting them. If the plants are healthy this is quite unnecessary. The structure in which they are grown being a stove, will be increased in temperature as the season advances; 55° to 60° being the minimum winter temperature, increase it to 60° in March, and increase to 65° or 70° in May. Pot them in the first week in March, the Pandanus in a compost of turfy loam two-thirds, leaf mould one-third, with a little sharp sand added; the Stephanotis in a compost of turfy sandy peat two-thirds, and one-third leaf mould or turfy loam, the latter in preference to the former. Add a little sand and drain well. The flowering depends on obtaining a free growth, and then well ripening the wood by a free exposure to light and a drier atmosphere, with abundance of air. The beauty of the Pandanus is its foliage, it being of no value on account of its flowers; the Stephanotis, on the other hand, is one of the sweetest and most beautiful of stove climbers.

POTTING FUCHSIAS AND PELARGONIUMS (J. B., Yorkshire).—Pot the Fuchsias in February, removing as much of the old soil as possible without injuring the roots, and place in the same sized pots, or a size less if such will hold the roots comfortably. Shift them into large pots when the pots become well filled with roots, transferring them to their blooming-pots (12-inch will be large enough), in the latter part of April or beginning of May. When the plants break out them in, so as to form an even-shaped plant, and when the shoots have made 3 inches' growth, take out the points of these. Continue the stopping, thinning, or otherwise regulating the shoots, so as to have an even-headed specimen, stopping for the last time in the beginning of June. If the plants are very vigorous they may be stopped until the middle of June, when they will mostly bloom in six or eight weeks afterwards. The Pelargoniums should be potted now into a larger size, and they should have their last shift in March. You will keep them close-stopped up to May to two or three joints, and afterwards tie out the shoots. They will most likely bloom at the time wished, but the bloom of Pelargoniums at that season is not so good as earlier in the season. We are obliged by your experience, affording us additional proof that our labours have not been in vain, and that our Journal is welcomed by all classes. You are indeed a veritable cottage gardener, and we gladly wish you prosperity. You ought to receive THE JOURNAL OF HORTICULTURE on the day of publication, or next day at latest.

HEADING-DOWN ELM TREES (A Subscriber).—If the trees have room we would let well alone. If they crowded you might either remove or head-in a part of them. We are not sure if we thoroughly understand your case.

PACKING ICE (H. C.).—In a small house we would make the straw into bundles and pack round the sides. If the house is of a fair size, and more especially if it have double walls, we would have no straw. As soon as the straw is wet it does more harm than good. Could you keep it dry it would be different.

PROTECTING PEACH BLOSSOMS (D. M.).—We have found canvass the best protection when it was let down at night and drawn up by day, and that sort of canvass known as tiffany we like best. Woollen netting with quarter-inch mesh is to be preferred when the days are cold, and it is then desirable to leave the covering on all night, it, like canvass, being taken off or drawn up on fine days and during mild weather. It is an excellent protection. A double covering of half-inch twine netting is also a good protection, and Spruce branches are sometimes used when nothing better can be had. Protecting materials can be had from most nurserymen at the price it is sold by the manufacturers, but we never recommend dealers.

PEACH BUDS FALLING (A Perplexed One).—We can only account for the buds falling through imperfect maturation of the wood, and that may have been occasioned through a deficiency of light by the shoots being too far from the glass, or shaded, a deficiency of water at the root, and also of atmospheric moisture, or the leaves may have been exhausted by attacks of red spider, and it may be the soil has been too dry during the season of rest. Their doing so well at the warmest end of the house sustains the opinion that the non-ripening of the wood is the cause of the buds falling in that part most distant from the fire.

FIGUS ELASTICA—COMPOST FOR VINES (E. Webb).—Pot the Ficus in March in turfy loam two-thirds, leaf mould one-third, with the addition of sharp sand. Pot the Vines forthwith in a compost of turfy loam, using it rather rough. Water with liquid manure at every alternate watering. Be sure and drain the pots well. Twelve-inch pots will not be too large.

**DRACENA COOPERI LEAVES BROWNED (T. T.).**—The probable cause is a deficiency of roots or a sour state of the soil. The plant is unhealthy, and that we have no doubt is occasioned by an inactive state of the roots. Repot, draining well, and plunge in a hotbed, and it will form leaves all right after a healthy root-action has commenced. Dryness is not a likely cause, but constantly syringing the leaves often causes these to die off at their extremities. Undue excitement also, or keeping the plant constantly growing, is a common cause of defective leaf-formation, but it is mostly for want of roots that the leaves go off in the manner yours are doing. The article on hybridising relates to any plant, and that on *Disa grandiflora* we think gives its culture, or relates to it, but we do not undertake to furnish that which can be readily obtained by a reference to our pages.

**GERANIUM SEED SOWING—CINERARIAS TO BLOOM AT MICHAELMAS (Geranium).**—The seed of the first sown early will not bloom, or but imperfectly, the same season. Cineraria seed to furnish plants for blooming at Michaelmas should be sown early in March.

**REMOVED ARBOR-VITES (S. M. L.).**—They will require no stimulants. Mulch the surface of the soil over the roots to keep out frost now and drought in summer.

**TRAINING FOR A GARDENER (Thankful).**—Having made so much progress, and you being able to manage a garden so successfully, why not employ the lad under your own direction? After a year or two of such instruction place him under the head gardener of some gentleman's garden for a similar period, by which time he would be qualified for an under-gardener's situation, or even the management of a small garden.

**BOOK (J. G.).**—The best edition of "Withering's British Flora" was published in four volumes by his son in 1830. Mr. Macgillivray edited an edition in one volume; also one of Smith's "Introduction to Botany."

**ANOTHER WILTSHIRE RECTOR.**—If you will send us a sealed stamped letter, undirected, we shall very willingly forward it to the gentleman you mention.

**BOUGAINVILLEA SPECIOSA AND LAPAGERIA ROSEA CULTURE (C. M. Major)** Pot the Bougainvillea in March, in a nine-inch pot, in a compost of turfy loam two-thirds, and leaf mould one-third, with a free admixture of sand, and grow on in a warm greenhouse, watering copiously up to the middle of August, then gradually withhold the supply, and expose the shoots to the full sun, and admit abundance of air. It should not be crowded by other plants at any stage, but have light on all sides. Keep the soil dry during the winter, but not so as to kill it. Its flowering depends on the well ripening of the wood. Another season employ a 12-inch pot. Pot the Lapageria in a 12-inch pot in a compost of turfy peat two-thirds, and one-third turfy loam, using both rough, yet in a broken state. Drain the pot to one-third its depth, and the drainage must be perfect. Train on a trellis, and if it have the northern side of a pan-roof, such is to be preferred; but a situation where it receives a full light, yet not the direct rays of the sun, will do. A cool airy structure is to be preferred, and one kept at 40° or 45° in winter. Give water every day, so as to make it show itself at the drainage, whilst the plant is in flower and growing, and syringe occasionally, keeping a moist but well ventilated atmosphere. At all times the soil should be kept wet, but double the quantity of water should be given when the plant is growing and flowering. Take care of the long and strong shoots, as from these the flowers are usually produced.

**TROPEOLUM TRICOLOR AND VALLOTA PURPUREA CULTURE (Yorkshire).**—Pot the tubers in 6 or 9-inch pots according to their size. If very small 4½-inch pots will do. Drain the pots well, and fill to half their depth with turfy loam half, and leaf mould or peat the other half. On this place the tuber, and when it pushes earth the shoot up as it grows, twisting it about in the pot taking care not to break it. In this way bring the soil to within half an inch of the pot rim. Water sparingly and only when necessary, at the same time keeping the soil healthfully moist. It will do well in a greenhouse in a light airy situation, if only frost be excluded. Pot the Scarborough Lily (*Vallota purpurea*) in a pot double the diameter of the bulb, in a compost of turfy loam with a little leaf mould added. Grow in a light airy situation in the greenhouse, watering sparingly at first, but copiously after growth commences. In winter water less, and give all the light possible.

**CLIMBERS FOR HOUSE-FRONT—BAYS AND LAURUSTINUS (A Young Gardener).**—*Wistaria sinensis*, *Aristolochia siphon*, *Bignonia radicans*, *Passiflora cœrulea*, *Pyracantha*, *Magnolia grandiflora*, also the Exmouth variety, *Lonicera brachyloba aureo-reticulata*, *Clematis lanuginosa*, *C. azurea*, *Jasminum nudiflorum*, and *J. officinale*. The Bays and Laurustinus should be fresh top-dressed in spring by removing a quantity of the old soil, as much as possible, and replacing it with fresh. It will not be necessary to put them in fresh tubs until the tubs are worn out, only they must be top-dressed and kept well watered. Both being rather tender, they should have a sheltered situation in winter. A good Rose for a wire is *Blairi* No. 2, Hybrid China. *Gloire de Dijon* is excellent.

**CAMPYLOBOTRYS REGALIS AND REPULGENS CULTURE (M. R.).**—They require the temperature of a warm stove more close than for the majority of stove plants. The temperature should not be less than 60° by night at this season, one of 70° or 75° at night in summer being necessary to secure a free growth. Pot them in turfy sandy peat two-thirds, turfy loam one-third, adding a free admixture of silver sand. Drain the pots effectually, using a moderate-sized pot at first, shifting into a larger as the small one is well filled with roots. Water sparingly, only keeping the soil just moist until growth fairly commences, then water more freely, but only when necessary. Place in a constantly moist atmosphere, and about 5° warmer than that of the stove generally. The secret of success rests in keeping up a close regularly humid atmosphere, but, at the same time, a sweet one. They are very impatient of water on the leaves, and should not therefore be syringed overhead. If you have no convenience beyond a regular stove, you will grow these plants best by having a frame made sufficiently large and deep to hold the plants, standing the pots on sand or gravel—better still, plunging them to the rim in sawdust or some such material. In this position a regular moist atmosphere will be secured, and they can have air by tilting the light, and this without any fear of sudden changes, which are the bane of the plants. Success in the cultivation of these plants lies in maintaining a healthy root-action, and in keeping all about them sweet and clean, being careful to avoid sudden changes of temperature—an atmosphere at one time humid, at another dry, at one time close and stagnant, whilst at another it is airy, and the atmosphere made cold or dry by admittance of air. A rather close, and rather warmer atmosphere than that accorded to stove plants generally, is just what suits these, and almost all the fine-foliated plants.

**FLOWER-GARDEN PLAN (E. W.).**—We never undertake planting. All that we can do is to criticise planting submitted to our judgment.

**FERN MANUAL (G. G.).**—It contains what you mention. The drawings were copied from live specimens.

**DESTROYING WOODLICE (C. I., Odon).**—When these pests are allowed to increase extensively they are very difficult to subdue. If it is not possible to introduce boiling water into the haunts of the woodlice, the most effectual way will be to raise the framework and destroy all of them that you possibly can; and then scrape away all the loose mortar, and bed the wood-work firmly down on to a layer of Portland or Roman cement, so that every crevice may be filled up and defy their making use of such a retreat. To destroy the stragglers that may have taken up their quarters inside the frame, boiling water may be applied to the inside of the walls, on which they are generally found creeping after dark. Poisoned fruits, such as Peas or Peaches, laid in the frame at night will also destroy them, as they are fond of feasting on fruit. Toads are great enemies to them, and one or two such lodgers will make short work of great numbers of them. Any or all of these remedies will enable you to overcome your marauders.

**NAMES OF FRUIT (J. Rust).**—Your Pear is *La Juive*.

**NAMES OF PLANTS (S. Edwards).**—1, *Blechnum spicatum*; 2, *Ceterach officinarum*; 3, *Asplenium Ruta-muraria*; 4, Specimen too imperfect. Any bookseller can inform you about the monthly magazines you name. (*H. M.*)—1, *Asplenium bulbiferum*; 2, *Asplenium lucidum*; 3, *Phlebodium areolarum*; 4, *Doodia*, or *Woodwardia caudata*; 5, *Platylopa falcatum*; 6, *Poly-stichum vestitum*; 7, *Adiantum formosum*; 8, *Selaginella Galeottii*; 9, *Adiantum reniforme*. (*J. B. H.*)—It is *Poinsettia pulcherrima*, a native of Mexico. (*J. C. Mundell*)—1, *Genesera zebrina*; 2, *Begonia argyrostigma*; 3, A *Begonia* which we cannot name from the specimen sent; 4, *Sericographis polita*; 5, *Calanthe vestita*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### JOINT-STOCK POULTRY COMPANY.

THERE is generally at this time of year a desire among those who think of the question to undertake matters on a large scale. So many schemes are afoot—some, we believe, going so far as to talk of a "Poultry Company, Limited," that we think we shall be doing well by touching on the subject. We have heard of one association or company seeking a hundred acres of light land in order to begin operations directly. We wish them every success, but we do not think it possible. The expenses would eat up all the produce. There is no doubt that a large supply of good poultry in the spring of the year would realise a great sum of money. It is no uncommon thing for young fowls properly fattened and killed to average £3 per dozen for weeks between the middle of April and beginning of July. It is a tempting sum, and soon runs into large figures; but it is also the most difficult season at which to produce them, and hence the price. Birds of equal or greater merit in the autumn and winter will make only half the sum. We believe in profitable poultry-keeping on a comparatively small scale, with new-laid eggs for sale at 4d. each during the winter, and a dozen fattened chickens per week during the spring. These in most localities and at all farms may be kept without involving any real extra expense. The return is for the small outlay of food, and a larger item of trouble and painstaking. We have been advocates for years for everything that would increase our spring supply of good poultry. It is needed; but the trouble and difficulty are so great, we believe we have made few converts among those who have the time and opportunity to follow our suggestions.

We believe the poultry raised in our rural districts might be easily and profitably doubled. It admits of easy explanation. Small land-holders who now fatten six dozen might as easily fatten eighteen. They have the conveniences at their homesteads of roosting-places, they grow the food, and they understand the question; yet even to these the remuneration does not appear sufficient to tempt them to enlarge their dealings. Profitable poultry must be produced in the scarce season. Chickens to be ready for the market in May must be hatched in December or January. It is difficult to get eggs then, still more so to find sitting hens. We know persons who have hundreds of fowls, and who have not yet had a broody hen this year. To breed profitably there must be a succession of fattened poultry to come day by day to the market. The process, then, of hatching, should begin in November and continue uninterruptedly. To lose a week would be to lose an advantage that could not be regained till the next year. The supply of poultry is like that of peas, fruit, &c., in the early spring. It is forced, and one is as artificial as the other. The outlay would be too great. Land to rent, houses to build, food to buy, men

to pay, carriage to London, commission on sales—these would all be heavy items, many of which are possessed without outlay by those who still decline to undertake poultry on a large scale. The truth is it is almost impossible, and hence the fact that there is in England hardly a person who lives exclusively by breeding it. Where fowls are kept in very large numbers they are very subject to disease. This disease spreads, and profit disappears.

Egg-selling in winter pays if you can insure a ready sale for new ones at a good price; and those that are laid in summer compensate in numbers for the diminution in price. In both respects we consider poultry as a valuable auxiliary to any one, and quite capable of considerably increasing a small income. We do not consider it a pursuit by which a living may be gained.

Many, some of them most valuable correspondents, have asked our opinion on the above questions. We have known no better mode of answering than by putting our practical opinions in the above shape.

### VISIT TO "Y. B. A. Z."

HAVING received, through the pages of this Journal, a courteous invitation from this now well-known writer upon poultry, to pay him a visit, I willingly accepted the kindness offered. I the more readily accepted the invitation because "Y. B. A. Z." promised to show me some Malays of such breed and beauty, as would either change, or greatly modify my opinion concerning this kind of fowl. I had written somewhat severely concerning the Malays exhibited at the Bath and West of England Show, and I was quite anxious to see some which I might like, for I am too fond of all kinds of fowls to have a prejudice against any one breed. This feeling adds greatly to one's enjoyment of a poultry show. I sometimes notice people anxiously pressing onward to see this or that sort of fowl, but passing by and not caring for any others. For my part I see so many and such varied beauties in the different kinds both of fowls and Pigeons, that I can pause at every pen. Local prejudices, or class prejudices, narrow the mind, and not only so but prevent much enjoyment.

A visit to "Y. B. A. Z.," the gallant defender of Brahmas, the criticiser of schedules. "But now tell me," whispers an inquisitive one, "Who is 'Y. B. A. Z.'?" "Do the four letters stand for a lady? if so, is she married or single, short or tall, dark or fair?" "Or do they stand for a gentleman?" Well, I may say this much, that the said four letters have in print owned themselves to be of the masculine gender, when not long ago they talked of doing battle with pistols. "Oh! but do tell me more?" "Alas! Miss Curiosity, certainly not."

"You have a vision of your own;  
Ah! why should I undo it?"

I had my vision, my dream, my imagination. I looked at the letters, looked again, then broke out triumphantly, "I have it, he is a Persian gentleman, remove the periods between the letters, and have but one capital, and the oriental name comes out plainly enough. "Ybaz," perhaps a merchant from Shiraz, or from the vale of Cashmere, he will quote the poems of Hafiz, not of Hood. Then is there not further evidence he is devoted to Brahmas, they are Eastern fowls at any rate, whether from Birmah or China, upon this point I give no opinion, valuing a skin unridled by pistol bullets. Doubtless, I shall find "Ybaz" wearing a high sugarloaf hat, possibly the whole Persian costume. I hope at any rate, he will not insist upon my worshipping the sun, as that would be awkward if it came to the ear of my Bishop. Well—

"I had a vision of my own,  
But, oh! time it did undo it."

Luckily Ybaz resides in England, I am to meet him at a certain railway station, and hold up a copy of "our Journal" in my hand as a flag of recognition. The ticket is taken, the journey is over, the said (or rather unsaid) station is reached, the flag exhibited and recognised. Ybaz does not wear a high hat; in short my hand in a moment is in the warm grasp of a thorough Englishman. We are friends at once. "There is the bond," exclaimed Ybaz, pointing to "our Journal."

I am not permitted to see the Malays until I am lunched. Hospitable and wise Ybaz, "a hungry man is an angry man," I shall look more kindly at your Malays, because the gnawing pains of hunger are appeased.

Now, be it known, that the Malays kept by Ybaz, are not Pheasant Malays, as were those shown at Clifton, which I am inclined to think are an inferior variety, but his are the older kind. Says "The Poultry-Book for the Many," "there is more difference in the appearance of the various specimens of this breed, than in those of any other breed." Among the best-looking are Ybaz's. They are of Mr. Ballance's strain, so naturally the *balance* is in their favour.

I would sum up in regard to Malays thus. They are an old and very distinct breed; much loved by our ancestors; kept years ago by that veteran in natural history, Mr. Waterton, and although as Mr. Baily puts it, "they have fallen before the spirit of utility," yet it is well that the best of this breed should be kept, and that there is a certain beauty in such as those possessed by Ybaz no candid person can deny. I hope amateurs who have means will keep up the breed.

I pass on from Ybaz's Malays to his Polish. These were Silver-spangled, and there was a trimness and beauty in these birds, especially in the cock, which I have seldom seen equalled, and I do not wonder at the unvaried success which has attended their exhibition.

Next, and most noticeable of all the stock belonging to Ybaz, came his Brahmas. These were the dark kind. I was introduced to some thirty cocks and cockerels living by themselves, and so easier to compare with each other than if mixed with hens. Certainly they were fine fellows; a sort of handsome heavy dragoons, and their colours well contrasting, they have not the mealy look of the light Brahmas. Their whole appearance, size, and distinct colouring mark them out to the eye, amid any number of other fowls. But if the cocks so seen in a flock, were striking, much more so were the hens. At the time I saw them they were kept apart in another yard, and certainly their most exact pencilling and gallina-like colour render them very pleasing to the eye.

I care not a rush from whence Brahmas came, what their origin; they have great merits, hence they are making their way, their one disadvantage as compared with Cochins is, that they must have a good run, but as to beauty, I place them before Cochins, followed closely, indeed, by the Partridge and Grouse. Talking of Cochins, Ybaz remarked that a hen of that breed is never seen to such advantage as when on the nest. He is right, then it is that you especially see the motherly, and sensible, and half-human expression of the face of the Cochin hen.

Well, I thought I had seen all; but, no, Ybaz was a good showman, he kept the best for the last, he opened a door, and out walked in solitary dignity his grand old Brahma cock, to which his others looked almost slim.

Having now seen all the fowls, we talked of gardens and roses. One hint I got, a valuable one to those who keep poultry, and yet love their gardens. Ybaz rears his spring chickens on a sunny border partly under glass (Cucumber-frames, I think), then when the chickens become bigger he moves all away, and plants the said border with Asters, and gets a late summer garden.

Time passed pleasantly away, when dinner came, and, oh! Ybaz—cunning man again—knowing I was an Englishman, you were bent upon converting me through my stomach, for lo! a cover is raised, and there lies revealed a roasted — *Malay*. Well, what there was of it was most excellent; but, Mr. Brent, the breast was sharp and thin compared to your Dorkings. Pleasant chat followed a pleasant dinner, and home again. The sun had shone on me all day, and I had not been obliged to worship that luminary, so I dared to look the Bishop full in the face at the Visitation a week afterwards. Onwards towards home, the back journey, the short walk, and I again neared my rectory, where I found as usual—

"There was a comforting fire,  
There was a welcome for somebody,  
There was a coat o'er the chair,  
There were slippers for somebody."

—WILTSHIRE RECTOR.

## POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.

(Continued from page 77.)

### ARTIFICIAL VERMIN NURSERY.

This is a very useful department in a poultry-breeding establishment; it will supply the poor prisoners with those dainty little morsels for which in their free state they never tire of looking after. It is well known, that from the chicken to the old hen fowls prefer insects and worms to any grain. In fact, fowls are omnivorous, but their carnivorous appetite predominates, and they would very soon become unfit for human food were they indulged in their predilection; but in a free state they have to perform hard work in their search for insects and worms, of which, after all, they find but a scanty supply. It will not, therefore, be advisable to give fowls in a confined state too much animal food, but only in such quantities as will be a stimulant and not injure their health. The effect on a hen fed too freely on animal food becomes soon perceptible; she will pull out her feathers and even peck her flesh until the whole of the upper part of her body is one mass of raw flesh.

It is not intended that the vermin should replace the minced meat in the food of poultry, but should occasionally be given in addition, as dainty morsels in wet or cold weather.

The vermin nursery is formed of a succession of pits with concrete bottoms, and the sides lined with brick; the top is covered with a trap to prevent the rain entering, as this might kill the vermin.

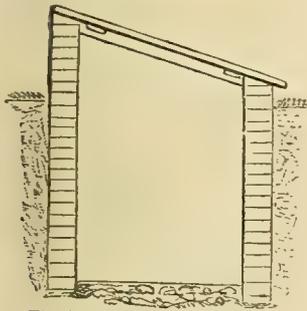

Fig. 23.—Section of Vermin Pit.

To propagate vermin, put in alternate layers of mould and vegetable and animal matter, such as horsedung, garden refuse, entrails of animals, dead animals, blood, &c., until the pit is filled. In a short time fermentation will commence, and the mixture will soon be converted

into a living mass of vermin. If the fermentation take too long it may be hastened by watering. In winter it is well to cover the mixture with horse manure, which will keep the vermin warm and alive.

This process of obtaining vermin is inexpensive, and it will be found very serviceable in winter for young chickens, and for stimulating the fowls to lay.

### POULTRY MANURE OR GUANO.

In the ordinary way of breeding poultry their valuable manure is lost, and we actually send ships to the Pacific and all over the world to fetch those very droppings of fowls which we despise to collect at home; yet in a large breeding establishment the collection of this manure, so much sought after by florists, will yield a considerable extra profit, which can safely be calculated at the rate of £50 per annum for every thousand fowls; but as vegetable growing, the refuse of which is good food for poultry, is almost a necessary adjunct to a large breeding establishment, the manure would be still more valuable to the proprietor.

### THE FEATHERS OF FOWLS

Are another extra source of profit in large establishments where they can be sorted and dried, as they will then command a much higher price, and this item may be computed at £10 per thousand head.

### THE MOULTING OF FOWLS

Is classed by many writers on poultry under the head of diseases, which it is not, but only a natural process with most animals in changing their summer coat for a winter one. Nevertheless, it is a great drain on their resources, and fowls during moulting ought to be kept warm and liberally dieted with warm and stimulating food—such as boiled oatmeal seasoned with salt and pepper, chopped onions, mashed potatoes, and occasionally bread crumbs soaked in strong ale or weak gin. Oxide of iron can also be

given at this time with great advantage. This diet will accelerate moulting and cause the fowls to resume laying at an earlier period than would otherwise be the case.

### DISEASES IN POULTRY.

Most books on poultry contain a more or less lengthy description of the various diseases fowls are subject to, and prescribe certain remedies, all of which help, no doubt, to swell the book, but are perfectly useless for all practical purposes. We might as well try to doctor ourselves for diseases of which we know nothing. The diseases in fowls may chiefly be ascribed to our variable climate, to dampness and cold, to injudicious feeding, and to ill-ventilated roosting places.

A diseased fowl, as will have been observed by many, is never kindly treated by its healthy companions, and in my opinion the best and most economical cure for a diseased fowl is to kill her before she is too far gone, and whilst yet fit for the market, and if not fit for the market, she will, when hashed up, make good food for the pigs. I acknowledge myself ignorant of the diseases of fowls, consequently of their proper treatment, and as I have no desire to teach the public that which I do not understand myself by simply copying from other books, I shall only state, that with judicious feeding and housing according to my plan there ought not to be one diseased fowl in a thousand.

### VARIOUS RACES OF POULTRY.

On this subject I would refer the reader for information to some special publication, as it does not exactly enter into the consideration of poultry-breeding in a commercial point of view. All that is necessary to know of the different races is to be able to distinguish those that are the best layers, the best sitters, and the best table fowls, and never mind about the particular points or feathers, the distinguishing characteristics of a pure breed. Now, where eggs are the sole object, some small breeds lay larger and more eggs than larger fowls. For this, Hamburgs, Spanish, and some cross-bred hens may be kept with advantage; and as for fowls that will do credit to the breeder for their weight after being fattened—Dorkings, Brahmas, and Cochins, and their crosses should be selected.

### KILLING AND DRESSING POULTRY FOR THE MARKET.

Almost every locality has its own system, but I may advert to a few facts on this subject. Poultry when bled to death is much whiter in the flesh; they will also keep much longer fresh when the entrails are drawn immediately after death, and the fowl stuffed as they do in France with paper shavings or short cocoa-nut fibre to preserve the shape. Some breeders cram their poultry before killing to make them appear heavy. This is most injudicious, as undigested food soon enters into fermentation, and putrefaction takes place, as is evidenced by the quantity of greenish putrid-looking fowls that are seen in the markets.

### MACHINERY, IMPLEMENTS, AND UTENSILS.

Without desiring to recommend any particular plan for saving labour, it is, nevertheless, desirable to state, that in any establishment of magnitude the expense for labour forms a prominent item, and it will, therefore, be to the interest of the proprietor to invest a certain capital in the purchase of such machines and utensils as will not only economise labour, but also perform the work much better than it could be done by manual labour.

The principal machines required are—a grinding mill for the grain; a pug mill for mixing the poultaceous food; a mincing machine for the meat and vegetables; a potato-mashing machine with wooden rollers; a sifting machine; a weighing machine, scales, and sundry smaller machines; also, a steam-boiling apparatus, a heating apparatus, and, in fact, such appliances as will not only economise labour, but also materials, and particularly fuel.

The manual labour itself ought to be sub-divided in such a manner that each person has his or her particular branch to attend to, in which each person will very soon become so expert that the work will be performed much better and in less than half the time.

### WHITEWASH.

A large quantity of whitewash will necessarily be required for sanitary purposes, but if prepared as follows, it will possess the advantage of preventing the wood from taking

fire, or from decaying. Dissolve in warm water sulphate of aluminium (alum), and sulphate of copper (blue vitriol), and mix with the whitewash.

#### LIME WATER

Is most beneficial for an occasional drink to fowls, it is a preventive of many diseases, and assists the formation of bone and eggs. Prepare as follows:—Pour over quicklime some warm water, and when the lime is slaked and settled draw off the clear liquid which can be kept for a considerable time. The lime will be useful for whitewash.

#### OXIDE OF IRON AND SULPHATE OF IRON.

Both can be purchased at a cheap rate from any drysalter, but they are so easily prepared that they may as well be manufactured on the establishment.

Oxide of iron (rust), is most useful for making and improving the blood, and a weak solution of sulphate of iron, which contains a large quantity of oxygen, will keep fowls in fine condition and assist digestion. Prepare this as follows: Take a quantity of old nails or small pieces of iron, put them in an earthenware vessel, then pour over them sulphuric acid diluted with water, the liquid will take up a certain quantity of iron and form sulphate of iron or green vitriol.

The rust or oxide of iron is obtained by mixing some diluted soda (the carbonate of commerce), with the sulphate of iron. The oxide will then be precipitated and the liquid forms sulphate of soda, which is a good liquid manure. The oxide of iron is mixed with the food of poultry, as given under the article of "Food."—G. K. GEYELIN, *Civil Engineer London.*

(To be continued.)

#### PIGEONS VARYING IN COLOUR—ICELANDERS.

I HAVE a pair of Black and a pair of White Fantails, and each of them reared last breeding season one chick, black and white (there being, however, very little white on the Black bird's offspring), and the feet of both are partly dark. You will suggest that there must have been infidelity on the part of both husbands, but I never observed it, and the Whites are a very quiet well-conducted pair. What I want to know is, Whether either of the above might have been cases of sporting?

What is an Iceland Pigeon or Icelfander?—T. T.

[Black Fantails were undoubtedly produced from the White birds by crossing, and the instance you mention is nothing more than a sport or going back to some former cross, and is no proof of inconstancy in the pairs.

I do not know what kind of Pigeons are meant by Icelanders or Iceland Pigeons. Perhaps some fancier will describe them. Are they the German Ice Pigeon?—B. P. B.]

#### BRADFORD POULTRY SHOW.

THE Poultry, Pigeon and Dog Show was held on Friday and Saturday, January 27th and 28th, 1865, in the Rifle Barracks, Manningham Lane. A detailed report will appear next week.

**SPANISH.**—First, W. Newsome, Bingley; Second, R. J. Wood, Lower Crumpsall, near Manchester. Third, J. Stephens, Walsall. Highly Commended, Viscountess Holmesdale, Staplehurst, Kent; F. R. Pease, Southend, Darlington; E. Brown, Sheffield. Commended, J. K. Fowler, Aylesbury; W. J. Cope, Barnsley.

**DORRINGS.**—First Cup, and Third, Viscountess Holmesdale, Staplehurst. Second, E. Coppel, Eccleston, Prescott. Highly Commended, T. T. C. Lister, Skipton; E. Coppel; Rev. J. F. Newton, Kirby-in-Cleveland; J. White, North Allerton. Commended, Sir St. G. Gore, Bart., Wirksworth; T. Statter, Whitefield, Manchester; J. K. Fowler, Aylesbury.

**GAME (Black-breasted Red).**—First, J. Fletcher, Stoneclough, Manchester. Second, Miss K. Charlton, Manningham. Third, H. Snowden, Great Horton. Highly Commended, Capt. Weitherall, Hethering, Northamptonshire; H. Snowden; H. Thompson, Milnthorpe, Kendal; Sir St. G. Gore, Bart. Commended, H. Thompson.

**GAME (Brown-breasted).**—First and Cup, E. Aykroyd. Second, J. Fletcher, Stoneclough. Third, S. Matthews, Rowmarket. Highly Commended, H. Snowden, Great Horton. Commended, J. Fletcher; H. Snowden.

**GAME (Any other variety).**—First, Sir St. G. Gore, Bart. Second, H. Snowden, Great Horton (Duckwing). Third, J. Fletcher, Stoneclough. Highly Commended, J. Anderson, Meigle, Forfarshire (Duckwing); S. Matthew (Duckwing); J. Ineson, Staincliffe. Commended, A. B. Dyas, Madely; W. J. Cope, Barnsley (Duckwing); G. Wostenholme, Sheffield.

**BRABMA POOTRA.**—First, R. W. Boyle, Dundrum, Dublin. Second, H. Lacy, Hebban Bridge. Third, J. Hinton, Hinton, near Bath. Highly Commended, T. Pomfret, Preston; J. Pares, Chertsey; R. W. Boyle. Commended, J. Stevens, Macclesfield.

**COCHINS (Cinnamon and Buff).**—First and Cup, Capt. Heaton, Lower Broughton, Manchester. Second, Miss S. Haylock, Cambridge. Third, R. White, Sheffield. Highly Commended, T. Stretch, Ormskirk; C. T. Bishop, Lenton, near Nottingham; Capt. Heaton; H. Bates, Yardley, Birmingham. Commended, J. Wood, Chorley, Lancashire; Rev. C. Spencer, Attleborough; C. T. Bishop; W. Newsome, Bingley; J. Shorthose, Newcastle-on-Tyne.

**COCHINS (Any other variety).**—First, J. Shorthose, Newcastle-on-Tyne. Second, R. Chase, Balsall Heath, Birmingham (White). Third, J. Stephens, Walsall (Partridge). Highly Commended, E. Tudman, Whitechurch, Salop. Commended, R. J. Wood, Lower Crumpsall; W. Bowler, Cirencester (Partridge); Rev. F. Taylor, Kirkby Lonsdale; R. White, Sheffield (Partridge); C. W. Brierley, Middleton.

**HAMBURGH (Golden-pencilled).**—First, Sir St. G. Gore, Bart. Second, S. Smith, Halifax. Third, F. Pittis, jun., Isle of Wight. Highly Commended, F. Pittis; A. Nuttall, Newchurch, Manchester; T. Hemingway, Shelf, Halifax; S. Smith. Commended, J. Preston, Allerton.

**HAMBURGH (Silver-pencilled).**—First, Sir St. G. Gore. Second, W. Lawtenson, Eaglescliffe Farm, Yorkshire. Third, W. Maude, Bingley.

**HAMBURGH (Golden-spangled).**—First and Timepiece, Sir St. G. Gore, Bart. Second, W. Driver, Keighley. Third, J. Smith, Keighley. Highly Commended, J. Roe, Hadfield, Manchester; W. Bayliss, Walsall; A. Milligan, Rutherglen. Commended, J. Mellor, Slaithwaite, near Huddersfield; T. Burch.

**HAMBURGH (Silver-spangled).**—First and Second, H. Beldon, Gilstead. Third, Sir St. G. Gore, Bart. Highly Commended, W. McMellon, Glossop; Sir St. G. Gore, Bart.; J. Fielding, Newchurch. Commended, J. Preston, Allerton; H. Beldon.

**POLANDS.**—First and Second, H. Beldon, Gilstead. Third, J. Smith, Keighley. Highly Commended, W. Newsome, Bingley; J. Hinton, Hinton; H. Beldon.

**ANY OTHER DISTINCT BREED.**—First, H. Beldon (Black Hamburgs). Second, J. Hinton, Hinton (Malays). Third, E. Pigeon, Lymstone (La Fliche). Highly Commended, S. Butterly, Keighley (Black Hamburgs); H. & G. Newton, Leeds (Black Hamburgs); Commended, J. K. Fowler, Aylesbury; J. Harrison, Blackpool (Crève Coeur).

**BANTAMS (Game).**—First and Cup, J. Munn, Newchurch. Second, G. Smith, Staveley. Third, W. Bentley, Bradford. Highly Commended, J. Munn; W. B. Mapplebeck, jun., Mosley; C. W. Brierley, Middleton; J. W. Morris, Rochdale; Miss E. Crawford, Southwell, Notts; J. D. Newsome, Batley. Commended, H. C. Woodcock, Leicester; J. Todd, Clifton, near Otley; C. Sutcliffe, Todmorden; R. Moon, Anfield; M. Redhead, Kendal.

**BANTAMS (Any other variety).**—First, J. A. & W. H. Briggs, Manningham (White). Second, F. L. Roy, jun., Nenthorp, near Kelso, N.B. (Silver-laced). Third, J. D. Newsome, Batley (Cochin Bantams). Highly Commended, A. G. Cane, Southwell (Booted Bantams); H. C. Woodcock, Leicester (Japanese); T. Davies, Newport Moor (Black); T. Boucher, Birmingham (Cochin Bantams); M. Leno, jun., Dunstable (Gold-laced and Silver-laced); E. Hatton, Pudsey (Silver-laced). Commended, Rev. F. Tearle, Leicester (White); T. C. Harrison, Hull (Scribble); H. E. Emberlin, Humberstone (White); W. B. Mapplebeck, Mosley; R. Adams, Handsworth, Birmingham (Silver-laced); Sir St. G. Gore, Bart.

**SELLING CLASS.**—First, T. Wrigley, jun., Middleton (Golden-pencilled Hamburgs). Second, J. Poole, Ulverston (Cochin). Third, H. Snowden, Great Horton (Game). Highly Commended, W. Whiteley, Liversedge (Spanish); T. Wrigley, jun. (Buff Cochins); T. Burch, Sheffield (Golden-spangled Hamburgs); F. Hardy, Quarry Gap (Polands); H. Snowden (Game); R. J. Bell, Hull (Game). Commended, J. Preston, Allerton; W. Bentley, Bradford (Game Bantams); E. Shaw, Oswestry (Spanish).

**SINGLE COCKS (Any colour).**—First and Cup, T. Statter, Whitefield, Manchester. Second, J. Fletcher, Stoneclough. Third, Hon. H. W. Fitzwilliam, Rotherham. Highly Commended, J. B. Chua, Coa brookdale. H. Snowden, Great Horton; Sir St. G. Gore, Bart. Commended, T. Bottingley, Shelf, near Halifax; C. W. Robinson, Sandfield Park; T. West, St. Helens.

**BANTAM COCKS (Any breed or colour).**—First, Cup, and Third, J. Munn, Newchurch. Second, J. D. Newsome, Batley. Highly Commended, Sir St. G. Gore, Bart.; R. W. Postans, Brentwood. Commended, C. Walker, Halifax; M. Leno, jun., Dunstable; W. J. Cope, Barnsley.

**DONKING COCK.**—First, Viscountess Holmesdale. Second, E. Shaw, Oswestry. Third, T. Statter.

**COCHIN COCK.**—First, E. Tudman, Whitechurch, Salop. Second, Capt. Heaton, Manchester. Third, E. Smith, Middleton. Commended, H. A. Hudson; R. White; W. Dawson; Capt. Heaton.

**GAME HEN (Any colour).**—First, and Timepiece, J. H. Cock, Worcester. Second, T. Burgess, Whitechurch, Salop. Extra Second and Third, H. Snowden, Great Horton. Third, T. Robinson, Ulverston. Highly Commended, T. West; E. Aykroyd. Commended, J. Anderson; J. H. Cock; J. Hodgson; J. Fletcher.

**DUCKS (Rouen).**—First, J. D. Newsome, Batley. Second, T. Wareing, Preston. Third, J. Nelson, Heaton Mersey. Highly Commended, A. Woods; H. Worrall; Sir St. G. Gore, Bart.; J. K. Fowler. Commended, T. Statter; J. D. Newsome; H. Worrall; W. K. Duxbury.

**DUCKS (Any other variety).**—First and Extra Third, J. Jennison, Manchester (Carolina and Teal). Second, Mrs. Seamons (Aylesbury). Third, T. Statter (East Indian). Highly Commended, T. Wotton (East Indian); Sir R. J. Clifton, Bart. (Aylesbury); H. E. Emberlin; J. Smith, Grantham (Aylesbury). Commended, Mrs. T. T. C. Lister (East Indian); J. K. Fowler (East Indian); Mrs. P. Wollerstan (East Indian); F. M. Hindle (Aylesbury).

#### PIGEONS.

**CARRIERS.**—Cup, F. Else, Bay-water. Second, T. Colley, Sheffield. Highly Commended, P. Eden, Salford; A. P. Leite; T. Colley.

**POWERS.**—First, P. Eden. Second, J. Scott, Wreckington. Highly Commended, C. J. Samuela, Longsight, near Manchester; E. Brown, Sheffield. Commended, G. H. Ellis; J. Scott; Miss L. Ashforth.

**TEMLERA (Almond).**—First, F. Else. Second, J. Ford, London. Highly Commended, P. Eden; J. Fielding, jun.; R. Fulton.

**TUMBLERS (Any other variety).**—First, P. Eden. Second, J. Ford. Highly Commended, P. Eden; J. Fielding, jun. (Kites); W. H. C. Oates, Newark (Beards); F. Else (Mottles).

**BARBS.**—First, W. B. Van Haansbergen, Newcastle. Second, W. H. C. Oates. Highly Commended, P. Eden.

**OWLS.**—First, P. Eden. Second, S. Sanday, Nottingham. Highly Commended, S. Sanday; J. Fielding, jun.

**TURBITS.**—First, J. Percival. Second, F. Else. Highly Commended, W. B. Mapplebeck, jun.; H. Yardley, Birmingham.

**FANTAILS**—First, W. B. Van Haansbergen. Second, J. Baily, jun., London. Highly Commended, G. W. Brown; C. F. Allison; F. Else.

**JACOBS.**—Cup and Second, J. T. Lawrence, Everton. Highly Commended, J. T. Lawrence; J. Thompson; F. G. Stevens.

**TRUMPETERS.**—First, J. R. Robinson. Second, W. H. C. Oates. Highly Commended, F. Else.

**ANY OTHER VARIETY.**—First, Rev. C. Spencer (Swiss). Second, W. Yardley. Highly Commended, E. Pigeon (Runts); J. R. Trenam (Spots); B. Leason (Nuns); H. Snushall (White Dragons); W. B. Van Haansbergen (Victorias); J. Harrison (Magpies). Commended, W. Ridge (Dragons).  
**SELLING CLASS.**—First, H. Yardley. Second, J. Thompson. Highly Commended, W. Messey (Carriers); B. Leason (Kites); S. A. Taylor (Owls); H. Yardley; H. Snowden.

**JUDGES.**—*Poultry*: Mr. R. Teebay, Fulwood, Preston; Mr. E. Hewitt, Sparkbrook, Birmingham; and Mr. John Douglas, London. *Pigeons*: Mr. Wm. Smith, Halifax.

## NATIONAL COLUMBARIAN SOCIETY'S SHOW.

THE annual Show of this Society, which now forms a great feature among the exhibitions of Fancy Pigeons, took place on Tuesday, the 24th inst., at the Freemason's Tavern. When we state that the Grand Masonic Hall was filled, as far as the circulation of visitors would permit, with pens, each well-stocked with choice birds, our readers may form some opinion of the strength and earnestness of this new Society. To give a description of each pen of birds deserving mention would occupy a large space in our columns. We are, therefore, compelled to speak of some that most particularly arrested attention.

Mr. Bacchus's stud of Carriers filling one end of the Hall, were conspicuous, but not more so than they deserved. We observed amongst them birds  $7\frac{1}{4}$  inches in limb, and  $19\frac{1}{2}$  in feather, very narrow in the girth.

Of Carriers, there were several pens of what may be termed the rising generation—slim, snake-headed birds showing that smartness of carriage, and that elegance of form which so strongly characterise this bird. The exhibitors were Messrs. Potter, Betty, Ord, and Feltham. Of the older or show birds there was the extraordinary collection of Mr. Else, a gentleman who is now considered the leader of the Carrier fancy. His row of beautiful birds was shown to great advantage in separate compartments of pens extending the length of the Hall. Blue Carriers also were numerous, and we were pleased to observe, that our breeders are now aiming to give to this colour what in so great a degree constitutes the Carrier—shape and carriage. Messrs. Ord, Feltham, Edwards, and Yates, showed good birds.

The bird replacing Carriers for flying long distances was exhibited by Mr. Hudson, whose birds were marked to have flown from 200 to 700 miles. We were struck on entering by the beautiful and rare pen of Black Mottles, the property of Mr. Smith. To see twenty-four Black Mottles and good birds in one pen is rare.

The Tumblers were represented by the Chairman, Mr. Jayne, by a pen, and ten pairs of Almonds and Kites; by the Almonds of Messrs. Merck, Park, and Walker; and the Baldheads of Mr. Morris.

The Show must have been a great treat to that largely increasing fancy, the Barbs, for of these birds there was a profusion. Mr. Jones came out in his usual force with Blacks, Duns, Yellows, Whites and Reds, Mottles, &c. Messrs. Walker, Dart, and Yates, also exhibited in this class good birds.

Of Toys the show was good and varied. The Jacobins of Mr. Morris showed those points the most difficult to produce, the clean thigh, the round head, the brilliant prestige. His collection of six pens was fine. Mr. Charles Allison, a Toy fancier, has risen almost to perfection in the fine show of White Fantails and Owls. Mr. J. Percival's pair of Blue Dragons fully maintained their prestige as a prize-getting stud at so many shows; nor must we omit that gentleman's show of Magpies, Jacobins, and Turbits. Trumpeters were exhibited by Messrs. Else and Dart.

Our readers on perusing this list will endorse our statement of the completeness of this Exhibition, of which we are happy to say the public availed themselves, a succession of visitors filling the Hall during the hours the Show lasted, and who seemed loth to depart, and lingered till packing the birds had been half completed.

## EXHIBITION OF BIRDS AT DERBY.

AN exhibition of birds is no strange affair in connection with Derby, for it is nearly eight years since the breeders of this town held their first public show—a local show—and which has continued to increase annually since that period. The breeders having multiplied and the interest having extended, coupled with the town being so centrally situated in England, induced a few of the most enthusiastic in the cause to extend their operations by opening (somewhat more than twelve months past) an exhibition, and offering liberal prizes for breeders to compete from any district in England. The result of that show was most successful, and stimulated the managing committee in their efforts to make the Derby exhibition equal to any. The local breeders hold their annual show in November, of no mean order either, and while kept at so respectful a distance (about two months apart) from the All England one in January, it acts somewhat as a feeder to this, and affords the breeders who may be fortunate enough to breed birds of a first-class description an opportunity of entering against any competitor, with all honour and credit due to them if successful. Such has been the case we know, for at the last grand annual All England show of Canaries, British and Foreign birds, and stuffed birds and animals, several of the Derby birds occupied prominent positions. The exhibition was on the 13th, 14th, and 16th inst., in the hall of the Mechanics' Institute.

The Canary department afforded a rich treat. The Norwich birds were pretty well represented, the first prize being given to Mr. Walter in class 1, for a bird well up in colour and size. The same exhibitor also won the second prize, and the competition ran somewhat close between it and the third prize and one belonging to Mr. G. H. Goodwin and another to Mr. Hewitt. The commended bird in the same class was good in form and feather but lacked somewhat in colour. The first-prize Buff bird was rightly calculated, and belonged to Mr. Mackley, who has shown some capital Buff birds in his time. With the other winners no fault could be found, the losing birds, especially Nos. 14 and 15, appearing very coarse and rough in feather, and No. 22 with the buff tinge not so good as many hen birds. Some excellent high-coloured and well-proportioned birds were shown in Class 3, but the bird that took first prize must have been judged more for colour than form, having a head and neck too raking, with variegation woefully deficient. In a mixed class as this was we do not agree with the prizes being all given to the yellow birds. There is no doubt that had the birds shown by Master W. W. Oliver been in a class set apart for Buff Variegated Norwich, as at the Crystal Palace Show, it must have stood very forward, for it is not only perfect in markings but good in shape and Buff colour, its only fault being the very slight crossing of the tips of the wings. The clear Belgian birds were fine in some points, although, as is generally to be found in an assemblage of "Yellows," the balancing game was going on with many. But it is more difficult to get them to appear (as a true fancier would wish) as the Buff birds do—namely, with heads and tails down and shoulders up. However, the best bird in the class deservedly took first honours and belonged to Mr. Corbett, of Birmingham, the second prize being awarded to a well-formed bird exhibited by Mr. G. H. Goodwin, of Derby, Mr. Rose, of Birmingham, carrying off third prize. The Clear Buff class, which was the largest, contained also the best birds, in fact the very best Belgian representative present. It was numbered in the catalogue 57, was exhibited by Mr. Rose, and awarded the first prize. We could not help admiring the bird as it appeared in the show-room, with its finely formed head; containing a pair of full and piercing eyes, which with its sweeping, snake-like neck on well-made shoulders and back, over which were evenly laid faultless wings, terminating with a tail long and fine, made it a gem of a bird. The underneath parts of the bird were also excellent, being favoured with a good chest and well cut off downwards. Although possessing as good a general form, colour, and feather as the most ardent admirer of this peculiar breed of bird could wish, still we must find a fault, but only a slight fault, with the stand of the bird, which was not quite equal to the second-prize bird shown by Mr. John Brown, of Birmingham which also was nearly as good a specimen; but failing in formation of head and quality of feather. The

third prize was won by Mr. Williams, of Nottingham, with a good specimen. There were several other good birds in the same class, mixed up with two or three sadly out of condition, especially one in a cage with No. 55 label upon it, and another with roughish feather marked 64. The Variegated Belgian classes were but middling, the first and third prizes in Class 6 being given to Mr. Corbett, and the second prize to Mr. Martin, Belper. One bird shown by Mr. Nicholson would have taken our fancy more had it been marked about the head to match with the wings. In Class 7 Mr. Phillips, of Basford, showed two good birds, with which he won first and third prizes, and one in particular was possessed of kind feathering but was somewhat small. Mr. Corbett's second-prize bird, and Mr. Goodwin's highly commended bird were fair specimens, but we cannot speak of the variegated classes as being so good as we have before witnessed. The Crested Belgians as they were styled, or the Manchester copy as we will call them, had five entries, and only a second prize was given. The Marked Belgian class contained several first-class birds, but we preferred the one which was awarded the second prize. The gold and silver spangled Lizards were very superior, the first prize in each class being won by Mr. Phillips. Mr. Chapman, Northampton, was awarded second prize for a Jonque Lizard; Mr. Williams second-prize for a mealy Lizard, and H. Ashton, Esq., won the third prizes in each class. The Goldfinch mules were exceedingly good, the first prize in Jonques being given to a choice specimen shown by Mrs. G. Barnesby, and which has won at various exhibitions eight first and three second class prizes in England and Scotland. H. Ashton, Esq., won the second prize in each class, and the third prize in Jonques was given to a famous bird belonging to Mr. Crocker, Plymouth, who also entered in the same class a curious-looking black mule. Mr. Edward Bemrose exhibited a rare mealy mule, with which he easily gained first honours, adding another laurel to three other first prizes at other exhibitions. In Class 14 a first prize was deservedly awarded to a rare mule, bred between the Goldfinch hen and Cinnamon Canary, belonging to Mr. Pointon, Basford, although we should have liked to have seen Mr. Lingard's Linnet mule with a prize also, but the class was not well filled. We never saw a bird more out of its place than Mr. Williams's Green Belgian, for the class was set apart entirely for mules or hybrids, and why should Judges have to contend with such a mixture? The cages containing collections of six birds each were most excellent, and numbered seven in the whole, six of them receiving high commendations. Three of the seven aviaries contained Goldfinch mules, and were exhibited by H. Vauncey Crewe, Esq., of Calke Abbey, Mr. Walter, of Winchester, and Mr. G. J. Barnesby, of Derby, the latter exhibitor winning the first prize with a superb and even collection. The mules shown from Calke Abbey were the next best. The half-dozen yellow Norwich Cocks belonging to Mr. Walter were very showy birds.

The British birds generally were very fine in plumage, but we did not think the Bullfinches so good as previously, and the first-prize bird must have been judged more for its size than plumage. As to the Goldfinch class, which numbered 17, all good birds, we must admit never having seen such an assemblage of these gay-looking little fellows. The Judges were quite right in giving an extra prize in this class, and we may remark that so good were many others that they were fully deserving of prizes. The Brown Linnets were fair samples, and the winner was correctly placed, although had Mr. Key's birds been in smarter attire it would have run the winner close. The Skylarks and Blackbirds were rightly judged, although in the latter class the losing birds were fine, one of them belonging to Mr. John Litton, Derby, was worth seeing only for the curious formation of its mandible. The first-prize Thrush was especially good, and the company it was keeping added no disgrace, the class being noted as very beautiful. There was one solitary Starling, and with no competition no prize was given.

The classes for foreign birds were made up as follows:—One rose-breasted Cockatoo, but no award made. Seven Grey Parrots were present for competition, and formed a conspicuous and interesting feature, some being rather talkative. The first prize was given to Mr. T. Bidulph's bird, and the second to Mr. Corbett's, the bird which gained first prize last year being commended. There was no entry

for Green Parrots, and a second prize was given to Mr. T. Harper, for a pair of Australian Grass Parrakeets, although we believe the awards would have been otherwise, had not one bird escaped from cage 201, and could not be caught until hunger induced a discontinuance of its flighty diversions some time after the awards had been made. In the extra Foreign class, Mr. Booker, Liverpool, took a first prize with a West Australian King Lory. In the same class, Mr. T. Harper, Derby exhibited a fine Lory Parrakeet, and Mr. Scrimshaw, of Nottingham, a pair of Cockateals, pairs of Diamond Sparrows, Java Sparrows, Indigo blue birds, and African Waxbills. There were three entries for collections of Foreign birds, two of which put in an appearance, and the first prize was very justly given to that belonging to Howarth Ashton, Esq., whilst a commendatory card was attached to Mr. Walter's cage.

Many fine birds, and several pens of poultry, were sent for exhibition and sale, including a Goldfinch and Canary mule braced and fastened to a frame of very tasty design, with a small box which the bird lifts the lid of to feed from, and also affixed to the frame is a little vessel from which the bird draws up water. It belongs to Mr. Bembridge, Nottingham, and was much admired. Mr. J. W. Price showed a large pen containing several fine golden Pheasants. Mr. Walter exhibited half a dozen drawcages with Goldfinches and Redpoles as occupants, which when hungry were obliged to draw up an inclined board a small waggon, descending each time the bird fed. Mr. Edwd. Bemrose's very rare specimen of a Linnet, a pure white one, commanded much attention, as well it might. Mr. Scrimshaw, also sent three Grey Parrots, a Macaw, several Indigo blue birds, Siskins, and Bramblefinches. Mr. J. Price sent a Brown Owl and a Hawk, and some well bred fowls were shown by Mr. G. Crewe, Mr. Pountain, Mr. E. Bemrose, and others. Several choice dogs were also exhibited by Mr. Bunting (one a winner of three or four prizes), Mr. Rickard, Mr. Chapman, and Mr. Martin. Great praise is due to the Secretary, Mr. J. W. Price, and others of the Committee for so conducting the Show, and who wish to express their thanks to the librarian of the institution and also his wife (Mr. and Mrs. Davison), for their courtesy and assistance rendered.—*GEO. J. BARNESBY, Derby.*

#### PHENOMENON IN HIMALAYAN RABBITS.

I HAVE kept Himalayan Rabbits for the last twelve years, and it is quite a common occurrence for one out of a litter to be black, and before two months old it turns perfectly white. I give mine no water, and very little green meat, principally feeding them on oats and bran.

I observe an advertisement in your paper, offering Himalayan Rabbits for sale at 12s. a-pair; allow me to observe that 6s. a-pair will buy mine, perfectly thoroughbred.—*HIMALAYAS.*

#### MR. LANGSTROTH, THE AMERICAN APIARIAN.

"OUR Editors" have done me no more than justice in believing that I should hasten to correct any error that I might have fallen into with regard to the above-named distinguished gentleman.

The apianian readers of THE JOURNAL OF HORTICULTURE can bear witness, that I was the first to introduce Mr. Langstroth's valuable book to their notice, and that I have always spoken most highly of it. By me also was it first brought to the knowledge of my friend, Mr. S. Bevan Fox, who has only echoed my own sentiments in fully appreciating its merits.

In according to Mr. Langstroth the credit of introducing the frame-hive and German method of managing bees into America, I had not the slightest intention of representing him as either borrowing or copying from our Teutonic brethren without the most ample acknowledgement. The facts of the case, which are no doubt correctly stated by him, both in his letter to "our Journal," and in his excellent work on "The Hive and Honey Bee," seem to amount to this, that substantially the same results were worked out

by careful observation and laborious experiment on both sides of the Atlantic pretty nearly at the same time without concert or copying one from another. It matters little, however, to English apiarists whether the American or the Teuton were actually first in the race, which so far as we can judge from Mr. Langstroth's statement appears to have been nearly "a dead heat;" all we should do, and all I am desirous of doing, is to accord the full mead of praise to each, and to thank both most heartily for the good service they have rendered to the cause of scientific bee-keeping.

Most sincerely do I congratulate the conductors of "our Journal," on the prospect of so valuable an addition to their staff of apiarist contributors as the Rev. L. L. Langstroth, and I can assure him, that by none will his contributions be more eagerly watched for, or more warmly welcomed, than by—A DEVONSHIRE BEE-KEEPER.

## A NEW CHAPTER IN THE NATURAL HISTORY OF THE BEE.

BEE COMMOTIONS AND QUEEN ENCASUREMENTS.

(Continued from page 81.)

THE last case I mention is that of No. 5, a frame-hive.

On the 12th of April, 1861, I examined this hive as no young bees had yet shown themselves, and as I had observed several small drones, imperfectly formed, extruded. My suspicions were aroused in consequence. I detest those little malformed drones. Their appearance always denotes something abnormal, and is suggestive of impending ruin. I drew up the frames and found in two worker-combs drone brood sealed, and several small drones with imperfect wings at large, but no worker brood sealed or hatched. A considerable number of eggs and larvæ were noticed in contiguity to the sealed drone brood. The cells sealed were all elongated, and as in ordinary drone cells they had the same convex coverings. The queen was not so feeble-looking as that of No. 13 above alluded to, whose queen was also a drone-breeder. On the 24th and 30th of April renewed agitations manifested themselves in this hive, and on examining it on this latter date, I found the queen had disappeared. I gave this hive a piece of brood-comb, but, as in the case of No. 13, it failed to rear a queen.

From these and other cases of a kindred character, I concluded that the encasement of these queens and consequent commotions were entirely caused by their extreme age and their abnormal condition as drone-breeding queens.

The only queen I ever had which ceased to lay altogether, either drone or worker eggs, was in 1862, and this was one of the two sent to Mr. Woodbury for microscopic examination in the autumn of that year, as already stated.

I have already given illustrations of the third class of queens being subject to imprisonment—namely, such young princesses as are not timeously fecundated. I have had instances of young queens, however, which remained perfectly sterile throughout the entire season so far as I could discover, and which I consequently presumed had failed to get fecundated at all.

In 1861, in consequence of the extraordinarily unfavourable character of the weather, a great number of the queens I artificially reared during that season failed apparently to get fecundated at all. Two became drone-breeders, and one queen reared in July after having been seen taking her usual aerial excursions, appeared again in August after the hive had been sent to the heath, and again during a very mild day after the hive was brought back, about the end of September. On the latter date she repeatedly came out, took a short circuit, and returned. When returning a number of bees on the board watched her proceedings, and on her attempting to alight repeatedly darted at her in the air, and struck her down to the ground. This, however, I have frequently noticed before in similar circumstances, and the only object the bees have in such freaks appears to be, to induce her to extend her flight for certain obvious reasons. In consequence of the repeated assaults on this occasion, the queen appeared really unwilling or afraid to enter. She flew about the whole apiary curiously examining other hives as if wishing to enter them. Having rested on a low hedge I caught her, and as I had other queens in my apiary at the

close of that inauspicious year in the same unsatisfactory condition, I resolved to retain her, and in this way I was enabled at little trouble to present a reserve queen to this hive which was adopted.

I may also state that I once reared in a unicomb hive, in July, 1860, a queen which was somewhat malformed—a marked and considerable indentation being conspicuous on one side of the abdomen. She in due time, however, became fertile, although never very prolific. In the autumn of the following year, 1861, one of my hives at the heath, some twelve miles distant, lost its queen, and I despatched a messenger with instructions to present this queen to it to keep it from giving way. My friend performed the message successfully, as I afterwards found in the following spring, when, on the 15th of February, I introduced the same malformed queen and her subjects into her old unicomb domicile, in which she had been reared. On the 8th of March, on looking into this hive, I noticed the queen was encased in a cluster of bees. I beat the hive, but though all the rest of the bees went into intense commotion, the bees in the cluster never let the queen out of their hold. I opened the glass, took a twig, and separated her from the bees. Under the irritation produced by my separating them, one bee curved its body as if in the attitude of stinging. The queen, however, moved nimbly off uninjured, but pursued by the bees. Some days afterwards I found the bees again in commotion, and on examining the interior I found the queen had entered a common cell, her posterior part only being visible. I opened the glass, and found her dead. I had a strong impression at the time that the physical defect or malformation of this queen might have had something to do with her untimely end, and this impression has, I think, been confirmed in some other instances in my experience where defective queens were superseded by the rearing of new ones. One of the most extraordinary cases of this kind occurred in my apiary during the last season—so extraordinary indeed in the circumstances attending it as to eclipse all others. A notice of this case, however, I must reserve for some future occasion. Suffice it here to say that for the first time in my apiarist experience there was exhibited in one of my hives the wonderful phenomenon of two fertile queens living together in apparently the most perfect amity and concord.

My treatment of the curious phenomena now under discussion, would be incomplete did I not allude to some other instances of queen encasements not yet specially referred to.

Let us briefly inquire therefore:—

1st. What are the effects produced by introducing a queen into a hive already possessed of one?

2nd. What are the effects produced by the union of two or more swarms with their queens? And

3rd. What are the effects produced by the introduction of a queen into a queenless hive?

As to the first question, then. In 1859, I had in my observatory-hive a queen which had been deprived of a hind leg. Whether this defect had any influence on her prolific powers I know not (she was by no means very fertile), but it produced a peculiar eccentricity in her ovipositing, which was very detrimental to the prosperity of the colony. Very frequently in attempting to deposit an egg in a cell which she had previously fixed upon, the abdomen would be thrust altogether into a contiguous cell in which an egg had been already laid. The result of this was, that numbers of cells contained several eggs. I noted a case which was narrated by Herr Mehring, in the German "Bee Journal," and inserted in this Journal by Mr. Woodbury, in August, 1862, which bore some resemblance to the one now stated by me. In this case, however, the queen had been deprived of two of her feet; but though at first her laying was of the same character as I have described above, yet at the end of four days the oviposition became more exact, and afterwards quite normal. On the 13th of May, having a spare fertile queen, I wished to see how the bees would receive and dispose of her. I opened one of the glass frames, placed the stranger queen on a part of the comb unoccupied by the bees, and shut the frame. The queen had scarcely time to move from the spot where I had placed her, when her presence was challenged by a host of sentinels that instantly attacked and surrounded her. The queen tamely submitted, and from 5 o'clock P.M. to 8 o'clock the following morning the

bees held her captive. I removed the cluster out of the hive, when I noticed a bee affix its sting in her body, and I had some difficulty in extricating it, even after the queen was dead. In such encasements as this, the bees not only seize the queen by the wings, legs, proboscis, and antennae, but sting her most unmercifully, and even retain possession of their victim till the very juices of her body appear to be sucked away, and when she falls from their relentless hold she looks like a withered dried-up carcass which has been exposed to the action of the atmosphere for weeks.

In 1858 I tried a similar experiment in this observatory hive by introducing a stranger queen, and the results were almost identical. The cluster formed around the queen I detached from the hive, put it aside under cover, and one might roll it about like a ball, so tenacious were the bees around their hapless victim; and they thus remained almost like a lifeless mass until I forced a separation, when in this case the queen was found dead in less than half an hour.

**2nd Question.**—To try the effects produced by the junction of swarms. On the 1st of October, 1859, I had the bees of two driven hives in separate skeps with their queens. These I beat out simultaneously upon a cloth, and permitted the conjoined bees with their queens to enter an observatory, in order that I might witness the results. The bees were very numerous, and some time elapsed before all were domiciled. Shortly after, in looking through the glass for the queens, I discovered one encased half-way up the comb, with a circle of bees having their heads all directed to a central point, in which the queen, from the smallness of the intervening space betwixt the comb and glass, was distinctly seen. She was simply imprisoned, but no attempts were made to sting or injure her. The other queen, I discovered, had been arrested on the floorboard, and surrounded also by a cluster of bees. This queen I disengaged in order that I might put her in as favourable a position as the other. With this view I introduced her at the top of the hive, and she descended on the comb, but she was instantly seized and surrounded as before. Both queens were thus under arrest. Meantime the bees got very agitated, and one-third of the entire population rushed out, took wing, and would have entered another driven hive, which happened to be sited near by, had I not anticipated their intentions by shutting that hive up. I immediately, therefore, disengaged the queen first noticed, and showed her at the entrance, when in an instant a rush of bees followed her into the hive, and all the truants on wing speedily returned. Again the queen's progress was obstructed beyond the entrance, and most of the bees clustered outside the hive. By afternoon the bees quieted down, but neither of the queens was yet released. Next morning, on examining the interior, I found one of the queens at liberty, and the other was extruded dead before the hive. The largest queen was retained.—J. Lowe.

(To be concluded in our next.)

### CONDENSED MILK.

Most American citizens have seen this article retailed from carts at their doors. In appearance it is a thick creamy-looking substance, of the consistency of molasses, which is afterwards reduced to suitable thinness by the addition of water. The advantages derived from condensing the milk are that it keeps sweet much longer, and is perfectly pure. This last is not the least desirable quality, for the consumer adds as much or as little water as he chooses. We have used this milk in our family in large quantities for a number of years, and find it a very great convenience as well as luxury. For coffee it is far superior to common milk, and for young children, suffering with complaints incident to them, this condensed milk is invaluable in respect of purity; swill-fed, or otherwise impure milk is the last thing to give a sickly, teething child.

The *New York Observer* contains an account of the process of making condensed milk at Gail Borden's factory, which is the one alluded to by us, and for which Mr. Borden obtained a patent several years ago:—

"The farmers bring their milk daily; it is poured into an immense boiler, the superfluous parts driven off, and the condensation effected in a few hours. The details of the process are exceedingly curious and worth studying. Everything is conducted with such scrupulous regard to cleanli-

ness, that the result is irreproachable. Even the large cans, in which the farmers bring their milk, are cleansed by steam before they go back. This prepared milk is sold daily in New York from door to door, as any other milk is, but its chief market is in the army, where it is a great blessing, as you will readily believe.

"The same process is applied to the juice of Apples, and other fruits, and meats. Coffee is condensed in the same way. Indeed any article of food may be condensed by this summary operation, be reduced in bulk, with all its nutritious qualities preserved, and packed so as to be preserved fresh any length of time. To make the little cans, holding a pound each, a tin shop is at work constantly, and the workers are women exclusively. They are chiefly American girls from eighteen to twenty years old, and as the machinery is driven by water and steam power, they have no heavy work on hand, and the business is admirably fitted for them. They make more than a dollar a-day easily, and the shop makes about 8000 cans daily. A carpenter's shop makes the packing-boxes, and so the entire work from receiving the milk to sending it off, is done in the factory, and this stands on the edge of the railroad at the depôt, so that all labour of transporting is saved. My visit to this establishment was very interesting and impressive, for I do not recollect ever seeing a factory where so much order, cleanliness, and comfort were combined in a production so purely beneficial as this. It is the perfection of the art of condensing.

Mr. Borden can condense 12,000 quarts of milk daily at this factory, and 20,000 in another at Brewster's station on the Harlem Railroad below, and there are four or five others in operation; one at Winsted, Con.; one at York, Pa.; one at Livermore Falls, Maine; and two in Massachusetts. They will doubtless become more and more numerous as their great advantages and profits become known."—(*Scientific American*.)

### RANCIDITY IN BUTTER.

YOUR correspondent "COCHIN" sends you some butter and wishes you to account for its rancidity. Of course, I cannot do that, but the inquiry has brought to my recollection a remedy for the taste of turnips in butter, which may be worth the attention of some of your readers.

Some years ago on an angling excursion to the beautiful trout stream, the Washburn (a tributary of the Wharfe), I was driven by a heavy shower of rain to take shelter in a farmhouse, and found the farmer's wife making her butter ready for the market. On asking her if her butter tasted of turnips she said, "Oh, no, my butter never tastes, I know how to prevent that." I said, "That is a secret worth knowing. How do you manage?" She replied, "When the milk is brought in from the cows, I have always a kettle of boiling water on the fire, and to every gallon of milk I put half a pint of the scalding hot water. I carefully stir milk and water together, then set it away, and my butter never tastes of turnips. Try the experiment and you will find it answers."—T. G.

### OUR LETTER BOX.

**BREEDING DUCKWING BANTAMS** (*Hy. N.*).—You may breed Duckwings from the birds you mention; it is often done to get the chestnut wing and saddle, and the black breast.

**PIGEONS AT JEDBURGH SHOW.**—In your report of the Jedburgh Show it is stated that my Owls were disqualified, but no reason is given. I entered a pair of Owls, and the white cock died before the Show, and not having another all white, and not wishing the pen to be vacant (as I was sending three pens short besides), I sent a white cock with a black tail. Individually they are first-class birds, but not being a match they were disqualified. It may have been absurd of me sending them, but I would rather be thought absurd than dishonest.—J. R. ROBINSON.

**LOP-EARED RABBITS** (*A Beginner*).—The points are—1, length of ear; measuring across the head from the tip of one ear to the tip of the other 2, width of ear; 3, colour; 4, position of ears; 5, largeness of eye; 6, carriage of body; 7, size. You can have "The Rabbit Book" from our office free by post for seven postage stamps; in it you will find much information you will do well to possess.

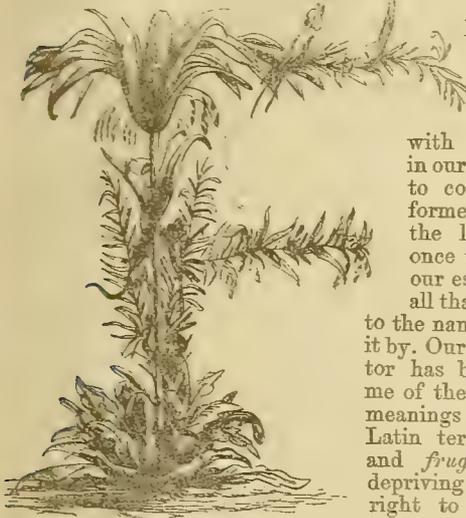

**PARROT STRIPPING OFF ITS FEATHERS** (*W. H. W.*).—We have repeatedly warned our correspondents that a Parrot doing this is suffering from intense irritation, induced by over-stimulating food. Parrots in a wild state are strict vegetarians, and to give them meat and bones when confined is to stimulate them unnaturally, at the same time that they are deprived of exercise in the free air. Feed your Parrot upon bread and milk and fruits only. At the same time give it a tepid bath daily, as we recommended on the occasion to which you refer.

WEEKLY CALENDAR.

Day of Month	Day of Week	FEBRUARY 7-13, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 45.1°, and its night temperature 30.9°. The greatest heat was 65° on the 10th, 1831; and the lowest cold, 0°, on the 13th, 1855. The greatest fall of rain was 0.67 inch.

HOUSE SEWAGE AND FRUIT.

FRUIT and flavour are ideas so intimately associated with each other in our minds, that to conceive the former apart from the latter is at once to rob it in our estimation of all that entitles it to the name we know it by. Our village doctor has been telling me of the distinctive meanings of the old Latin terms *fructus* and *fruges*, utterly depriving me of any right to quote the "*fruges consumere*

*nati*" in support of my, to him, very ultra fruit-eating propensities. Somewhat extending the meaning of what were, no doubt, household words in the mouths of the old Roman pomologists, I now include among the "*fruges*" that very large percentage of nominal fruit which, alike on the market stalls, the dessert-table of my friends, or in the produce of my own orchard, has no claim to a more dignified classical term than the Turnip or the Potato. I have somewhere read of the Turnip, not cooked but neatly cut into slices, handed round to their visitors by some of our continental neighbours. There at least there was no pretence; but to have bright rosy emblems of all that conjures up to the mind the idea of a delicious Apple presented to one, to result when tasted in a disappointment, recalling the fabled Apples of Sodom, is carrying the sham too far. "*Fruges*" forsooth, I must ask the doctor for some Roman word infinitely less noble, the better to express the relative inferiority to Turnips of at least nine-tenths of all the Apples this end of Cheshire sends to market. But for the Jargonelle from a wall, the Marie Louise in ordinary seasons, even from a standard, and some others, far too few, "*fructus*" itself is lacking to convey what the word "*delicious*," which it were sacrilege to apply to anything else but the best of good fruit, is alone fitted to express.

Flavour is very much a relative term. He who has once tasted British Queens at their best is likely to have a very different notion of the word as applied to Strawberries, compared with him to whom Keens' Seedling has been the standard of perfection. Even now it is difficult to understand how, only thirty years ago, the Royal Horticultural Society ranked as first-class dozens of varieties which now exist possibly only in their cata-

logue. Year by year our standard of flavour has been gradually advancing, and as old trees decay and newer sorts come more extensively into bearing, we shall have an immense progress in the public demand for the very best. It is remarkable to notice the harmony of opinion as to flavour in fruit; for, take any mixed company, and from the infant of two years to the old man of eighty, the verdict as to the comparative merits of two or more given sorts is almost invariably unanimous—so at least we have found it at the meetings of our family pomological society; and I am surprised that market gardeners and fruiterers have not long ago seen it to their profit as a mere matter of business to make the general public better acquainted with first-class dessert fruit by attaching tastefully-executed labels to the baskets upon their stalls. Depend upon it that he who once bought Winter Nelis by name will ask again and again for the same fruit ere long; demand will stimulate supply, resulting at last in cheap and abundant provision of delicious fruit, "*familiar in our mouths as household words.*"

"UPWARDS AND ONWARDS," in a late Number of this Journal (December 27, page 507), has noted a very important fact on the question of flavour in fruit, showing, it would seem, pretty conclusively that liberal waterings with house sewage, repeated at intervals, exert a very powerful influence on the formation of the various secretions which go to constitute flavour in the Apple and Pear. Now, flavour being altogether a product of a period of the tree's growth when any supply of moisture, and above all of moisture containing sewage, would in every way tend to defeat the object in view, it is an interesting matter to inquire how the happy result referred to in the paper on "*House Sewage*" has been brought about. What "*UPWARDS AND ONWARDS*" has done is the very thing hundreds of enthusiastic fruit-growers have been puzzling their brains how to effect, and if we can see clearly how this has been brought about, there is no reason why what has been done in one well-regulated garden should not be done in every one equally so, within a reasonable approach to it in climate, soil, and situation. I presume the garden referred to is somewhere in the upper valley of the Thames, and, therefore, presenting points in common with a very large section of the country.

In the annual growth of every fruit tree, and to a great extent in that of every fruit, there appear to be three successive stages, indicated in their pomological relations by the three phenomena of the setting, the growth, and the ripening of the fruit. Passing over that important affair of the blossoming time, when the hopes of the fruit-grower are bound up with delicate operations of Nature, which a night's frost or a shower of rain may effectually defeat, let us suppose the fruit fairly set upon trees in the open ground, and ready to profit by the first abundant watering with sewage. We have now, as it were, so many centres of attraction, each attracting and retaining the food elaborated by itself and the leaves in its immediate neighbourhood, and there is little doubt that this process of increase should receive no check till the fruit has reached nearly its full size, or at all events

entered upon its ripening period. A week of cold weather, or a drought of a fortnight during the growing period, puts in peril not the size merely, but also the quality of the produce. Big Apples are unfortunately only too seldom first-rate for dessert, still, as a rule applied alike to big sorts and little, the largest fruit on a given tree are also the choicest in flavour and in texture. The Golden Pippin has charms in its very littleness, but the biggest of the same crop are invariably the best. In passing, it may be asked, Has it been noticed that in fruits generally, when colour is a constant quality, does not the flavour bear some relation to the intensity of the colour; the brighter and the more brilliant the red, the richer and more luscious the juice? Not that highly coloured varieties are in any way superior to those of dull russet, but in varieties having a tendency to colour, or even to russet, are not the individual fruits in which that tendency is most strongly developed, also the best?

Of the positive increase of size, however, there is one portion that would seem more properly to belong to the ripening than the growing period. I refer to that rapid increase in the size of the Cherry and Plum accompanying the change of colour. Does the actual weight of dry solid matter increase during this change? or is the increased size only an accommodation of the size of the vessels to the altered nature of their contents, which are now less amy-laceous and more saccharine? The latter are soluble in water, the former not so. Is the increase in weight not wholly or principally in water absorbed during the ripening process?

Though not so patent, a similar increase seems to take place in the early part of the ripening period of Pears, and I think also of Apples.

The great agents in furthering the production of good fruit during the growing period are light, heat, and moisture. All these are essentials during the entire life of the plant; but, as during the blossoming period, a moderate proportion of each seems all that is requisite for our open-air British fruits; and as, whilst the fruit is ripening, light and heat in quantity, with only a very limited supply of moisture, seem the most favourable conditions, so during the growing period an abundant supply of all three is a necessity. Of light and heat we have never enough to satisfy us, and, somewhat strangely, the limited quantity of the one has been almost universally accepted as a circumstance we must submit to, and, quite as odd, endeavour to compensate for by a disproportionate increase of the other. Some day when we have learned to concentrate upon 9 square feet of soil or leaves the solar rays that would otherwise fall upon two, three, or five times that superficies, we shall have more light thrown upon fruit and fruit-culture.

Of moisture, the third essential during the growing period, we want abundance, and yet we may have more than enough. The natural supply, more especially in this country of naturalised fruit trees, where we want a dry soil and atmosphere to ripen our Cherries in, at the very time when precisely opposite conditions are required for Apples and Pears, is proverbially fickle. So thoroughly, indeed, are we at war with the elements that we may be longing for dry weather for one Cherry, whilst another Cherry equally good would suffer from lack of moisture. The clouds persist in dropping their fatness at most unreasonable times, and always either too much or too little. And here comes in the great question of house sewage and irrigation generally, forced on the attention of both gardener and farmer by the trying season of 1864. Prophets like "UPWARDS AND ONWARDS," who for fifteen years back have been crying aloud in the wilderness to a very heedless generation, have not preached altogether in vain, and the lover of good fruit will see that he, too, may share in the good things foretold if he but consent to turn to its proper use what, if it run to waste, entails heavy retribution upon the spendthrift in a fearful crop of half the ills an hospital is heir to.

Implying by the term "house sewage" all the excreta of the household very largely diluted with water, it may be accepted at once as the cheapest, most effective, and most elegant medium by which in the fruit garden the soil may be compensated for what is abstracted from it by the fruit. The term "elegant" may be a little out of place in a matter of manure, but nearly all adjectives are relative only. As

Liebig says—and a very odd remark it is to occur in a volume on agricultural chemistry—"At all times the better has always been the enemy of the good;" so is house sewage, applied as I saw it yesterday, elegance itself alongside my neighbour's ashpit-emptying of last week. If your garden produce more food than your family consume, and artificial manure be necessary, add it in a soluble state to your sewage; it is then in the best of all conditions to assist successful fruit-culture. However vegetables may thrive on such fare, Strawberries and Gooseberries, here at least, rejoice in copious libations of even extra strength. "UPWARDS AND ONWARDS" says better still for Apples and Pears, and all analogy coincides with his successful practice.

Of all the rainfall in this country in the course of the year somewhat less than one-half finds its way through the crust of the soil, re-appearing, perhaps, in springs and rivulets; the remainder and greater part is returned to the atmosphere by evaporation from the surface of the soil, or from the leaves and other parts of plants. This, however, is but an imperfect statement of the case, for from well-ascertained data it has been calculated that in the summer months in the eastern counties of England the evaporation of moisture reaches as high as 97 per cent. of the entire rainfall in the same period. No doubt for a considerable period much of this is retained by the soil, contributing to the furtherance of vegetable growth, and finally escaping to the air through the stomates of the leaves after having fully accomplished its mission; but the fact that such a small proportion as scarcely 3 per cent. should find its way through the soil by filtration, shows what a fearful check even a very moderate drought must entail upon such fruits as are at the time in their growing period. If, as should be, the rootlets are near the surface, the effect is proportionately increased.

Very unfortunately for the fruit-grower, meteorologists are not all gardeners. Their recorded observations are not tabulated, as they might and should be, first of all in relation to vegetation, the chief end that makes the weather worth studying. We are still treated to the antiquated tables of mean temperature of days and months, as if that were the essential element in the measurement of the atmosphere's caloric, to the virtual suppression, or nearly so, of the average and extreme maxima and minima, which are the only very important points. Very hot days and very cold nights may be the best of all weather, and yet the tables indicate a July with a mean temperature below the average. So, too, as to rainfall. We may have three very wet days in the beginning of the month, and as many near its close, evidencing quite a maximum of wet, and yet the weather of the month may be characterised by intense dryness. Mr. Glaisher, in his abstracts, is happily reforming the method of expressing weather facts, and gives us, both as to heat and rainfall, the length in number of days, of cycles of heat or cold, rainfall or dryness. This is reasonable. We may have a few very cold days, which pull down heavily the average maximum of an otherwise very brilliant month; or an average month, less favourable to plant-progress than a month with alternate cycles of heat and cold, resulting in the same average maximum as the other. Ere long, I hope, in every garden we shall have a cheap sunshine-indicator, measuring the most potent influence of all, the duration each day, and at what times of the day, of the direct solar rays—wonder-working, above all things else, in both animal and vegetable worlds. Now that we know so much, we can afford to look half lovingly, as well as half pitifully, upon the ancient fire-worshippers of the old time before us.

With so fickle a friend as rainfall to help us to grow delicious fruits, sometimes deluging us beyond our heart's content, at others withholding the longed-for showers, we may consider ourselves as twice blest in having it within our power to make at least a portion of it do double duty. We have happily not often, as in 1860, a preponderance of really wet weather all summer through. We have oftener to regret the lengthened intervals between the wet cycles; and at these times, by previously carefully storing up the water which usually runs to waste, we have, in irrigation, and, in a double sense, in house sewage plentifully diluted, the means of supplying the deficiency in the natural element.

I may have failed fully to comprehend the system of irri-

gation followed by "UPWARDS AND ONWARDS;" but it seems difficult to understand how only two abundant waterings could so materially affect the quality of the fruit. Very wisely, he seems to have apprehended the bearings of the old proverb—"It never rains but it pours," and gives a real, hearty, wholesome watering when he is at it. One hundred tons per acre is roughly calculated at an inch of rainfall, and each of his waterings slightly exceeds an inch and a half, together exceeding a full month's natural fall. Twice, however, seems too seldom in the average of summers for fruit which does not begin to ripen till September or October. The secret of his success must lie in the careful selection of the most profitable times at which to apply the sewage—once, he says, just as the fruit is fairly set, and again when half grown.

How this sewage watering should affect for the better the flavour of the fruit is worth a little inquiry. I have six Sturmer Pippin Apple trees, dwarfs on the Paradise stock, which for some years back I have taken special delight in subjecting to all manner of torture in the way of experiment. The Sturmer does little good with us here (Cheshire), as a standard, and even on a wall, though keeping well, it is never first-rate. In a favourable season it becomes mellow in April or May, but this is the exception; and I have noticed that in ordinary years the cells of which the fruit is formed are smaller and more compact than in the best of seasons, the fruit being also less in size. The same remark applies to the fruit of such dwarfs, in a dry summer, as I have transplanted the previous autumn. In the latter case the leaves seem to have ripened prematurely, and ceased to nourish the fruit. In specimens of the Sturmer, which I have at present from standard, wall, and from under glass, there is a regular gradation in size, in compactness of cell, and in flavour; perhaps, also, in specific gravity. Now, may not the application of house sewage, as favouring increase of mass, tend to increase of the size of the cells, and therefore increase of their contents, perfecting the fruit for entering in due time upon the ripening period, when starch, and fibre, and acid, as by the wand of a magician, are transformed into that delightful combination of "rich, sugary, and delicious," which the pages of Hogg's "Pomology" taught me, years ago, to look for in so many of our best varieties, grown where they can be, and as they should be.

The subject is an interesting one; and if I have been tempted to be too critical, or over-confident in my views, I shall be glad if "UPWARDS AND ONWARDS," or any one else, will help myself and others to a better understanding of a fact so many must have welcomed, as opening up a way to the increase of the varieties of fruit which the average of soils and situations can produce of really first-rate quality. The subject widens as it is looked upon, and a long array of questions rise up, insisting each upon its answer. How may sewage be best applied so as to avoid the loss of temperature consequent on all surface irrigation? Should the liquid be heated before application, and to what degree? and is there any economical means by which its temperature may be elevated, with, in its results, a real profit, calculated in pounds, shillings, and pence? At what times, and how often, should irrigation be employed, and in what quantity? Will not each fruit, and each variety, claim a distinct treatment for itself? But, truce to questions; like every other new idea (and yet, whilst new, a very old one), if there be anything of value in it, discussion, by interested minds, will elicit all that is worth having; and, meanwhile, we may thank "UPWARDS AND ONWARDS" for suggesting new answers to the now-popular query—"What shall we do with our sewage?"—FRUIT-EATER.

## THE MODERN PEACH-PRUNER.

### No. 3.

#### PHENOMENA CONNECTED WITH GROWTH.

THE substances necessary for the life of plants are absorbed by them from the soil, by means of the roots, and from the atmosphere by means of the leaves. De Jussieu calls these last "aërial roots." Their functions, in some degree, resemble those of the human lungs. They absorb from the air the water and carbonic acid which they require. Roots draw from the soil mineral and saline materials,

besides the carbon and nitrogen which artificial manures supply.

The spongioles alone are the absorbing organs of the roots, nutritive substances are introduced by them in the form of liquids, which proves how indispensable water is to vegetation. Fluid nourishment is, therefore, the basis of the growth of plants. It is elaborated in the leaves, under the influence of the solar rays during the day. Under the name of sap it ascends to the leaf-stalks, passes into the venous ramifications, and from thence into the cellular tissue of the leaf. A portion is returned to the atmosphere, the rest remains to feed the plant.

The carbonic acid of the air is also absorbed by the leaves, unites with the matter drawn by the spongioles from the soil, and is decomposed in the tissue of the leaves, in order to become nutritious matter.

The sap elaborated in this manner takes the name of cambium, and changed in the nature which it had during its ascent, it becomes proper and suitable for the increase of the plant. The sap ascends to the leaves through the outer layers of the alburnum, or young wood, during the day. It descends during the night to the spongioles by the innermost layers (that is, by the newest formed) of the liber, composing thus a new layer of ligneous fibre, and a new layer of liber. This is the manner of growth in trees. There is, however, this difference, that while the ascent of the sap increases the length, the descent of the matured sap, or cambium, increases the breadth of plants.

In spring, the sap-vessels are already gorged before the leaves show. Thence arises a pressure on the axils of the buds, which precipitates the young shoot into extension. The cambium descending, on the other hand, solidifies the young shoot by means of the new layers which it interposes. The cambium gives breadth as well as solidity. We can thus readily comprehend how a shoot which has pushed forth in some portion of a tree, deprived of the sun's rays, is unnaturally long, and soft in its component parts. The leaves of that shoot not having been exposed to the action of light, the cambium has not been elaborated in the texture. The sap remains much as it was during its ascent; the inner portion of the growing shoot is spongy and soft, the cambium being the means of hardening it, and the shoot has received little or none. On the other hand, a shoot which springs from that side of the branch which is fully exposed to light is short, and the wood is hard, well coloured, and fruitful.

The descent of the cambium is by the innermost layers of the liber, and it forms the ligneous layers which cover the medullary canal, and also the new vessels of the liber.

These ligneous and cortical layers, when formed from the cambium, elaborated in the upper leaves, are placed above those formed by the lower leaves. The ligneous layers are, however, composed from the centre outwards—*i.e.*, the newest layer is that farthest from the centre. But the cortical layers are formed from the circumference to the centre—*i.e.*, the newest layer is the innermost. Each year, then, a new layer of alburnum covers that formed during the preceding year. When the cellular tissues are filled in they become hard, and of a deeper colour. This is the "heart" of the tree; but the sap does not pass through these obstructed vessels any more. This portion, however, is the real support of the tree against violent winds. In like manner each year sees new liber grow, while the oldest layers, now external, possess no longer vitality, and become dry and wrinkled.

The growth of roots is owing to the descent of the cambium, by the addition of new cellular tissue to the spongioles. It is evident, then, how mutilation of these is injurious to the welfare of the tree, and how a healthy equilibrium between root and shoot is a first requisite to its healthy vitality. When these spongioles become obstructed they cannot absorb the materials of the soil, and thus the tree languishes and dies. A portion of the cambium in the autumn does not descend to the roots, but is reserved by nature to feed the young shoots before the leaves expand in spring. In shoots, the inner epidermis is formed by the aid of this reserved cambium. The first action of the spongioles in spring, may also be due to its influence in some measure.

In like manner we may readily understand the growth of the fruit. Fruit is composed of cellular tissue; like the

leaves, the epidermis is full of stomata or mouths. The parenchyma of fruits has its functions as well as that of the leaves. The sap ascending from the roots is developed therein, the useless portions are evaporated into the atmosphere, the nutritious substances remain in the cells, where they are decomposed by the oxygen to form nutriment for the growing fruit. These fruits absorb a very large proportion of sap for their own use, and do not restore it to the general use of the tree as the leaves do. This is how the too abundant production of fruit exhausts the vitality of the tree, and how the crop of one year affects that of the next.

During the period of growth fruits inhale carbonic acid, and exhale oxygen. But when quite ripe they absorb oxygen, and set free carbonic acid. When, then, all this acid is disposed of, and replaced by oxygen, the fruit is perfectly ripe, and decay is not far off. In all these processes we see what an important part water plays, whether in the soil as the means of conveying the nutriment to the plant, or in the air in the condition of vapour. In the soil it dissolves the substances it meets there; in the body of the tree, as sap, it is the vehicle of these nutritive substances, and in the air, in the state of vapour, it remedies any undue dryness of the soil. A superabundance of humidity is, however, an evil. Trees grow, but produce but little fruit when moisture is too abundant.

Not less important than water is air. Without it the sap would not be converted into cambium. The roots decay when withdrawn from the influence of the air. Soil must, therefore, be permeable.

Without light trees could not feed, nor produce fruit. Light accelerates the maturing of the sap, by causing an evaporation of the superabundant water in the cellular tissue of the leaves. The roots are thus stimulated to absorb more liquid nourishment. The more light, the more root-action. A bright light is needed for the leaves to decompose the carbonic acid accumulated in their tissue. Light flavours and colours the fruit.

Heat is also an indispensable agent in vegetation. It stimulates the energy of plants, especially when combined with moisture. Even during periods of great heat the sap, then much stimulated, brings into the leaves some of the coolness of the soil derived through the roots, thus preserving the leaves from being injured by the solar rays. During the winter, on the contrary, the sap circulates very slowly, but still brings with it something of the latent earth heat, which is higher than that of the atmosphere, and thus counterbalances its coldness.—T. COLLINGS BRÉHAUT, *Richmond House, Guernsey*.

### THE CLIMBING ROSE DEVONIENSIS.

HAVING read in your paper "D., Deal's," remarks on new Roses, I find he mentions having received from Mr. Curtis, of Torquay, two plants of a Rose said to be a fixed sport of *Devoniensis*, and named by him a climbing *Devoniensis*. It may be interesting to your readers to know that a Rose similar in every respect to the one named by "D., Deal," has been most successfully cultivated and sent out by Mr. S. Pavitt, nurseryman, Rose Cottage, Bath, for the last seven years, and it is the true *Devoniensis*. There are several large trees of this Rose in close proximity to the town, and growing with great luxuriance; one in particular has reached the height of 40 feet and is 19 feet wide. It is very hardy, having withstood the severe winter of 1860, blooms in great perfection all the season, and is almost an evergreen.

I visited Mr. Pavitt's nursery this season, and saw fifteen hundred plants of this Rose, budded on the Briar, flourishing to a degree almost beyond belief; nearly all had shoots 3 feet and some of them measured 9 feet in length, with three, four, and five shoots to each plant, and all of the previous year's budding. Many of the trees were in full bloom, and most magnificent the blooms were.—T. F. ANDREWS, 3, *Locksbrook Place, Bath*.

EARLY KING POTATO.—In reply to the inquiry of "E. W." I beg to state that a season or two since I received from a friend residing at Bude, North Cornwall, a few sets of a new

Potato, I believe raised and only known in that district, under the name of "The Early Emperor." They are in shape flattish-round, colour rosy red, very shallow-eyed, and altogether a remarkably handsome Potato. They were highly recommended to me for their cooking qualities. Of the latter I cannot speak from experience, as up to the present my aim has been to secure a sufficient stock. Should this prove the kind wanted by your correspondent, I shall, on receiving his address, be only too happy to send him a few sets.—JAMES NICHOLLS, *Higher Market Street, Tavistock*.

### PROPOSED EXHIBITIONS OF THE ROYAL HORTICULTURAL SOCIETY.

We have been requested to publish the following memorial which has been presented to the Royal Horticultural Society.

TO THE COUNCIL OF THE ROYAL HORTICULTURAL SOCIETY.

The undersigned members of the Exhibitors' Society and other exhibitors beg to call the attention of your honourable body to the very objectionable arrangements just announced for the exhibitions and meetings of your Society during 1865.

It is with great regret that we feel bound to comment on them in this manner. They have, however, been condemned by the entire horticultural and floricultural press, and we consider them to be diametrically opposed to our interests as exhibitors, as well as to that of the Royal Horticultural Society, and totally adverse to the practical purposes of horticulture.

It is not our object or wish to dictate to the Council. On the contrary, it is our earnest desire to co-operate with them if they will meet us in a practicable form; but with the arrangements as they at present exist we must most respectfully decline to exhibit at any of the Royal Horticultural Society's exhibitions for the year 1865; and we feel it our duty as horticulturists to communicate this intention to the Council without delay.

At a meeting of the Exhibitors' Society held a short time since, the following letter from a distant member, a well-known and successful grower of Orchids and other plants, was read, and heartily approved as embodying the views of the members generally:—

"Your letter respecting the meeting of the Exhibitors' Society is to hand. I am sorry it is not convenient for me to attend, owing to the great distance I am from you, and the loss of time it would entail.

"As the meeting is to take into consideration the programme of the Royal Horticultural Society, I may venture to express my opinion of it in a few words.

"In the first place, I decidedly object to the shows at South Kensington taking place on Saturdays. If necessary I might even enforce a stronger argument on behalf of myself and other country exhibitors living at a great distance from London than the one so ably written and published in the *Gardeners' Chronicle* for December 3rd, p. 1157, and signed "G. B.," inasmuch as those exhibitors who are situated as I am are obliged to make the journey home on Sunday, and unload our plants, which keeps us hard at work all day, besides having our several establishments unsightly on the very day they are required to be in the greatest order.

"The letter to which I have referred deserves to be read to the meeting as an answer to Sir Joseph Paxton's letter respecting his visit to an establishment near London when the plants were gone to win the stakes. It is what it deserves.

"In the second place, I consider the special weekly and floral decoration shows a complete farce. The fortnightly meetings might eventually be of some interest if small prizes were offered for small collections of different subjects in their respective seasons, in addition to awards which are at present offered for new and rare horticultural productions, so as to make them partake more of the character of a minor flower show—something after the character of the meetings which were formerly held in Regent Street.

"In the third place, I consider the whole general programme a great mistake, more detrimental to horticulture than otherwise; and I think this meeting should take into consideration the propriety of offering advice to the Horti-

cultural Society in time—that is to say, we should not, as a society of exhibitors, deeply interested, see it fall to the ground without some exertion on our part.

“As the expenses attendant on all these endless exhibitions, fêtes, &c. (and of no practical use), would ruin any society however wealthy, the fact that our young Society has been the means of working much good already should encourage us all to persevere in the good work.

“It is useless for me to say more, other than to give you some idea of the views I entertain regarding the Horticultural Society’s proceedings. Should you think it worth while you are quite at liberty to read this to the meeting.”

It will be seen that holding the exhibitions on a Saturday is one great grievance; but there are many other unsatisfactory matters of detail that cannot be stated in a letter, but which can if desired be pointed out by a deputation to confer with the Council, or otherwise, as they may decide.

It is right to add that it was unanimously resolved at the meeting above alluded to that—

“In consequence of the programme of the Royal Horticultural Society for the year 1865 being so diametrically opposed to the interests of exhibitors, the members pledge themselves not to exhibit at any of the Society’s exhibitions unless the arrangements are modified to a practicable extent.”

 CANNELL, —, Woolwich.  
 J. & J. HAYES, Edmonton.

We are informed that there are four or five other influential nurserymen, who, though they decline to sign the memorial, will act in accordance with the memorialists.

To this memorial the Council returned the following answer:—

Royal Horticultural Society, South Kensington, W.  
 25th January, 1865.

SIR,—I am directed by the Council of the Royal Horticultural Society to acknowledge the receipt of a memorial, which, on behalf of certain exhibitors at the Society’s former shows, you have done me the honour to transmit for the consideration of the Council.

The Council desire me to express their regret that the arrangements they have made in respect to the exhibitions of the ensuing season should have proved distasteful to any exhibitor, but as the programme has already been made public they feel themselves pledged to adhere to it. At the same time they would observe that they will not consider themselves precluded from introducing any modification or alteration in them that experience may hereafter prove to be desirable.

It would appear from the memorial that exception is taken—1st, To the special shows; and 2nd, To the day (Saturday) on which the great and special shows are to be held.

As regards the first, the Council have only to remark that their object in establishing what they have termed special shows was to give a fresh impetus to horticulture by calling special attention to particular tribes of plants; and as regards the second objection, they have only to remind the remonstrants that in making choice of Saturday they are but reverting to the practice of Chiswick in its palmy days, when the facilities for locomotion were infinitely less than at present.

The Council desire me, therefore, to express their hope that those who have signed the remonstrance will reconsider their decision as to the course they intend to pursue.—I am, Sir, your most obedient servant,

ANDREW MURRAY, Assistant Secretary.

Mr. O. Rhodes, Secretary, Exhibitors’ Society.

## ROSE GOSSIP.

FROM all quarters one hears the cry, “Never was there such a demand for Roses as this season.” The difficulty has been, I have been told by more than one grower, to execute the orders; while such kinds as have received favourable notice from time to time are so run upon that it has been impossible to obtain them. Charles Lefebvre, for example, has not only been largely increased here, but I know more than one nurseryman who has imported hundreds of them from France, and yet they have been “sold out.” This is very encouraging—encouraging to Rose-fanciers, for it promises them a treat, for unquestionably all this implies an increased number of exhibitors and perhaps of exhibitions; and encouraging to those who venture to act as guides in such matters, for it shows that their opinions are well read, considered, and acted upon, while it imposes on them great carefulness in their recommendations when they know that it is not merely that they are expressing their opinion, but that in so doing they are unconsciously acting for weal or woe on hundreds of others. I have ascertained that the demand for standards has not equalled in proportion what it used to be. It is just possible that the severe lesson taught in 1861 has led people to see the greater advantage of dwarf plants, or that the Rose is now more grown for ornamental purposes than formerly, and that standards are not considered so slightly. Doubtless there is a vast number still sold, but those budded on the Manetti and grown as dwarfs are more in favour. This being the case, I would desire to say a few words once more in favour of the plan adopted first either by Mr. Charles Turner, of Slough, or Mr. C. J. Perry, of Castle Bromwich—viz., that of pegging down the shoots instead of cutting them short back. I am sure that if it were tried with, say, a few only for the present year, the number so treated would be increased every year. To those who, like myself, dwell in a windy corner of the world this plan has immense recommendations; for so much am I exposed, that in one of our recent gales a dwarf plant of Cécile de Chabillant budded close down was blown clean out of the stock! This plan, known to many of your readers, consists in pegging down the shoots instead of cutting them back, the tip of the shoot being shortened a few inches. The result is that from each eye on the upper part of the branch a shoot springs, and when these are in bloom the effect is charming; and then from the centre, thus well exposed to all the influence of air and sun, shoots 4, 5, and 6 feet long start up in the summer. These are to be in a similar manner laid down, and the old ones cut away at the pruning-time some time in March. I am sure that if growers were to try it they would see the advantage of it. Of course, it is only when the buds are put in very low down that this can be done; and then the bud should be completely covered, by which means a double supply of strength is gained, roots coming out from the Rose as well as from the stock.

I find that I made a slight blunder in my notice of climbing Devonians in saying that the sport had been fixed by Mr. Curtis, such not being the case, as he tells me he is quite ignorant of the manner in which it was obtained; but the fact is none the less sure that to him is due the credit of

giving us a great acquisition to our gardens, for he informs me that he has had shoots on it 12 feet long—enough to make any one's mouth water; and as we have a climbing Fairy Rose in Cinderella, there is no knowing what sports we may have.

I have heard some rumours of reviving a National Rose Show, the proposed plan of having all shows at the Royal Horticultural Society on Saturdays completely precluding many of the most ardent admirers of the Rose from being present, and it being thought by many desirable to have an independent show, such as it was when first originated by Mr. Hole. Whether this will be effected it is impossible to say; but certainly there is no flower but the Rose which can support of itself an exhibition as it has done for years.

Have any of your readers, I wonder, experienced this result with regard to that excellent yellow Rose Celine Forestier, that when grown on a wall it will not flower, or at any rate flowers very sparingly? I had a fine plant of it that made shoots 8 or 9 feet long, but I had nothing but a few indifferent blooms; while on plants as standards and dwarfs there was an abundant bloom. *Triomphe de Rennes*, on the other hand, blooms profusely in the same situation. A knowledge of these points would greatly help Rose growers, and prevent much disappointment. Good folk often imagine that their little experience is not worth recording; but I am quite sure that if observations were more freely given, a great deal of valuable information might be gained.—D. Deal.

#### ROYAL HORTICULTURAL SOCIETY.—FEB. 4.

THE speciality for this occasion was Crocuses, but of these there were no exhibitors. Messrs. E. G. Henderson contributed a collection of fine-foliaged plants, comprising *Diefenbachia grandis* and *Baraquiniana*; *Ficus Lyalli*, with polished pale green foliage; *Ficus Grelli*, with shining dark green leaves, not unlike those of *Theophrasta imperialis*; *Cupania filicifolia*, with very graceful and elegant Fern-like leaves; *Dracenas*, &c. From the same exhibitors came also *Cyanophyllum magnificum* and *Sphærogyne latifolia*, the specimen of the latter with fine large broad leaves. For the above exhibitions Messrs. E. G. Henderson had first-class certificates. Mr. Bull, Chelsea, had similar awards for a collection of *Dracenas*, and another of *Agave*, *Yucca*, *Roelia*, *Beaucarnea*, and *Bonapartea*; and a second-class certificate for *Skimmia fragrans*, a fine new hardy shrub, which produces an abundance of fragrant white flowers.

Mr. W. F. Catleugh, Hans Street, Chelsea, exhibited a number of Chinese Primulas, well fringed and high in colour. This strain, it was stated, was obtained by selecting the highest coloured and most perfectly fimbriated, and fertilising the one with the other. For these Mr. Catleugh had a first-class certificate; and a similar award was made to Mr. Ingram, gardener to Her Majesty, for a finely-flowered *Rhododendron*; and to Mr. Miller, gardener to Lord Foley, Workop, for a basket of very good Mushrooms.

We take this opportunity to remark that the conservatory is now well worth a visit, the baskets along the front having been painted afresh; and Mr. Eyles has had them filled with Hyacinths, Early Tulips, *Solanum capsicastrum*, *Skimmia*, *Azalea amœna*, &c., variously arranged. The effect of the whole is excellent. In one basket, at the western end, *Berberis nepalensis* is producing numerous spikes, each about 8 inches in length, of its fine yellow flowers. It is evidently deserving of more extensive cultivation than is at present accorded it.

#### RABBITS AND BERBERIS AQUIFOLIUM.

IN answer to Mr. Fish's inquiries respecting *Berberis aquifolium* being eaten by rabbits and hares, I planted in 1862 about 3000 plants of it with Privet, Yews, Hollies, *Rhododendrons*, and other things, and I am sorry to say it is quite as much eaten by these animals as anything else. In fact, I think more so than the Privet, and it is not the young shoots they eat so much as the old wood. Even strong shoots 2 to 3 feet high they bite in two a few inches from the ground, and there is nothing I know of that escapes their nibbling propensities except *Rhododendrons*; and nothing makes a better cover where the soil suits them.

The best remedy I have yet met with is to dress the trees with coal tar very much weakened by mixing urine, night soil, and soot with it. Of course, the tar must not be used too strong, or the remedy will prove as bad as the disease.

I trust Mr. Fish's inquiries may induce others to give an account of their experience.—W. BROWN, *Elmdon*.

#### STRAWBERRY FORCING.

MUCH of the success attending the forcing of Strawberries depends on the preparation of the plants. The main points are to have strong plants with their buds well developed, and the pots filled with roots. Various modes of preparing the plants are adopted, but there are three which I know to be attended with very good results.

One mode is, to take the moderately strong runners in August, and prick them out in nursery-beds about 3 inches apart every way. If light the soil is made firm by treading it firmly. Water is given freely, and slight shade until the plants become established. The situation should be open. In this position they remain until the following March, when they are taken up with a little ball and potted in 3½ and 4½-inch pots—the former for the early forcing small kinds, as *Black Prince* and *May Queen*; the latter for main crops of the old *Wellington*, *Keens' Seedling*, *Oscar*, and *Sir Charles Napier*; also, for *British Queen* for late crops. The soil should consist of strong turfy loam from rotted turves a year old, chopped pretty fine with a spade, but not sifted; and for the culture of the Strawberry in pots I prefer this compost without any mixture of manure whatever. The pots should be washed clean both inside and outside, and but one crock placed over the hole. On this a little rough sod will also act as drainage, and the roots will ramify through it. If a little soot be sprinkled over it worms will not like to come through the hole, besides the Strawberry roots are particularly fond of the soot, which is the best of manures for Strawberries. Pot the plants firmly, and let the crown be elevated in the centre of the pot. Give a good watering and on no account allow them to become dry afterwards, watering overhead twice weekly with soot water. Soot water is a certain cure for the attacks of red spider. After potting half plunge the plants or pots in coal ashes in an open situation, and if the floor is formed of ashes and boiling coal tar it will be impervious to worms. The flowers should be pinched out as they show.

In June the plants will be strong, and should be potted forthwith into their blooming-pots, which should be six-inch for the early, and seven-inch for the main crops. At this potting the drainage is made more certain by placing more crocks at the bottom than in the former case, but three pieces of pot are ample; a little rough fresh sod is quite as good a drainer as a larger amount of crock drainage. Pot with the ball entire, and ram the soil around the ball quite firm. Be careful not to sink the crown but keep it well up, its base level with the surface, and allow a quarter of an inch below the rim of the pot for watering. The plants should be plunged as before, and be kept well watered, giving water overhead on the evenings of hot days. Move the plants frequently to prevent their rooting into the soil, cutting off the roots outside, which will cause fresh ones to be emitted inside the pot. The plants should not be huddled together, but have room for their foliage so as to enjoy light and air. Under no circumstances ought they to be suffered to flag for want of water. All runners should be pinched off close.

By the second week in September the plants should be stood on boards or slates about 1 foot from the base of a south wall, and no water given except enough to keep the soil just moist, and to prevent the leaves flagging. Towards the middle of October the plants may be placed in a cold frame, especially those intended for first work, the later sorts being plunged in ashes or tan in a sunny place, to be transferred to frames as room can be found for them. Whilst in the frame they are to have air daily, and protection from rains and severe frost by a covering of mats. These plants will please most people, and for a cold locality where runners cannot be had early it is almost the only mode of raising plants to have fruit early and with certainty.

Another method is to lay a runner in a small pot as early as runners can be obtained, placing a small stone on

it to prevent its being blown off with the wind, and if another runner show beyond the first cut it away. Water daily if the weather proves dry. In ten days or a fortnight the roots will show themselves at the drainage-hole; the plant is then severed from its parent, placed in a cold frame, and kept moist and shaded for a few days until it recovers the check consequent on its separation. In a week or ten days at the farthest the plants are potted in their blooming-pots, and treated in the same manner as stated for those from runners of the previous year, except that they are more freely watered after removal to a warm sunny situation, not diminishing the supply much until the end of September or beginning of October. These plants make good forcers, but will not produce so fine a crop, nor be so early or certain in their bearing as those from late runners of the previous year, at least they never were so with me; and it is in a great measure due to the hard pushing of young plants that the Black Prince is an indifferent setter early in the season.

A third method is to prepare six-inch pots for the small growers or early kinds, and seven-inch pots for the late sorts by placing two or three large crocks over the hole, and then a little rough compost. Placing a handful of soil in the pot, beat it firm with a rammer, and continue to add more soil and ram until the soil is level with the rim in the centre, but a quarter or half inch below it at the sides. The soil should not be very wet, but only just moist. The pots are then taken to the beds in the open garden—to those only which are in an open situation—and placed near the plants so that the runners can be laid exactly in the centre of the pots, making no hole or hollow, but simply placing the runner on the soil in the centre of each pot, and laying a small stone on it on the side next the old plant. If there is another runner above the one layered, cut it off close to that in the pot, and if any more are pushed pinch them off as they show themselves. The runners should be watered daily in dry weather, and though they will be rooted to the bottom of the pot in three weeks or so, they will obtain more strength if left attached to the parent until the middle of September than if severed when first well rooted. The pots should be raised frequently, and any roots that run through into the soil rubbed off when young and brittle. If the roots are allowed to take fast hold of the soil the plants receive a check they never recover, besides the roots are wanted inside the pot, which cannot be too full of them. When severed from the parent, the plant or plants should be removed to a sunny situation, placing the pots on rough ashes, or plunging them in ashes, tan, or sawdust, which is better. These form excellent plants for forcing after January; but they are not so good in my estimation as those treated according to the two preceding modes.

A fourth method, and it is the last that I shall name, is to take the earliest runners in the last week in July, if they are to be had, but not later than the first week in August. Select good strong runners and pot them in 60-pots, placing them in a close frame and shading slightly until established. The pots being crammed with roots, in three or four weeks the plants may be potted, the earlier kinds into 4½-inch pots, and these for the main-crop sorts into six-inch pots. After potting they may be placed in an open situation, sunny and sheltered, but not shaded on any account, and if plunged they are all the better. Here they may remain until the last week in November, when they should be transferred to a frame, orchard-house, or any cool house, and be kept dry rather than wet during the winter. These make nice plants for forcing after February, but they are of no value for hard forcing. It is a good system for orchard-houses and cool vineries, but the preceding is a still better one.—G. ABBEY.

(To be continued.)

#### UTILITY OF LOOSENING THE SOIL.

I HAVE seen at different times statements in your paper from Mr. Fish, and others, that the looser the surface, the greater will be the moisture of the soil.

Without questioning the experience of practical men, I venture to ask the reason of this. The looser and rougher the soil, the larger must be the surface of earth exposed to the air, and, consequently, the greater one would imagine the

evaporation to be. A block of ice, we know, is kept from melting by wrapping it in a wet blanket, the rough surface of the blanket throwing off, by evaporation, more moisture, and with it heat, than any covering of a smoother texture would do. How is it, then, that a like irregularity of surface does not produce a like rapid evaporation of moisture from a crumbling and friable soil? Is it that the loose soil is even more quick in imbibing moisture from night dews, than it is in exhaling it during sunshine? This is certainly the case with tan, which for the reason above stated, must evaporate largely, but which must absorb more; for, even if but an inch thick, it has always moisture underneath it. This power of absorption in a loose soil may account for its greater moisture, if there be no doubt about it, but I should like to be assured that this is the fact.

My object is more than to satisfy a curious inquiry. I have reason to believe that the firmer the soil is trodden round fruit trees growing on a light soil, apt to be scorched in summer, the more the trees will flourish. But if it be true that loose soil attracts moisture, then the more that in which my trees grow is trodden, the less moisture they will have, and moisture is above all things what they want.

I have looked into Thompson, Lindley, and Johnson, for information, without success. Perhaps best of all would be a soil beaten hard below, covered with half an inch of loose earth on the surface.—WYESSIDE.

[Loosening a soil by forking and other gardening processes, benefits in various ways the plants grown upon it. It enables the air to penetrate, and the oxygen and carbonic acid of the air are requisite applications to the roots of plants, and the moisture of the air is thus also deposited within the soil. Being so deposited, the looseness of the soil also checks its evaporation, for loose soil conducts heat, or becomes heated, much more slowly than the same soil consolidated, because the spaces between its particles are filled with confined air; air in a state of rest being one of the worst conductors of heat. A blanket is wrapped round ice to prevent its melting, because all woollens are bad conductors of heat, and one cause of their being such bad conductors, is that the spaces between their interwoven fibres are filled with air in a state of rest. That consolidated earth becomes heated more readily than the same earth loosened, has been proved by experiment. Tan and cocconut fibre refuse retain the moisture beneath them for the same reason, between their fragments are spaces filled with confined air. Consolidating the earth over the roots of fruit trees is one of the most fatal of practices, and where it is superlatively effected by having the surface turfed so that no loosening is effected for lustums of years, weakly trees with little of annual growths, but abundance of lichens on the trunks and branches, are the usual consequences.—EDS.]

#### PLANT JUDGING.

I AGREE with Mr. Findlay that plant judging, especially in the country, where local influence is brought to bear, wants looking into. Here are three judges—A, B, and C. A and B know one another, and agree to back each other, and “snub” down the impertinent observations of C. A or B, on arriving at a class, says No. 7 is A1. Exactly so, cries the other. C knows better, and will know presently that he may as well hold his tongue, or agree with deaf and dumb men. If you put two professionals and an amateur together, C will probably represent the amateur.

I cannot but think that concealing names is all moonshine. I never saw fairer adjudications than at the Rose Exhibition at the Floral Hall, Covent Garden, where every man's name was attached to his box. We want men of calibre, who do not care about offending any one, client, friend, or not. The maintained high character and integrity of such men will be more beneficial to them than favouritism and nepotism. The names of the three judges should be written on the prize card, and they should each be made to write opposite their names “For” or “Against,” as the case may be. This would make them cautious; and the people will then see their judgment, and, if competitors are disappointed, they will still be better satisfied. No doubt such a plan is open to objections; but erroneous judgments and intentional dishonesty are open to far greater. If men are

determined to be dishonest, I fear there is no other cure but to get rid of them. The publication of the names of competitors, and the judgments, will enable you to catch more easily (if guilty of palpable favouritism) nurserymen and amateur "chums," and nurserymen and amateur clients. As to country places, the nepotism is fearful.

I only throw out the above as a hint, which more experienced persons may improve upon. I hope false delicacy will never hinder any one from stating his objections to anything that I advance. Human nature is human nature, and I am not for allowing it the flimsy veil of mere nominal concealment. See the folly of it. I helped the year before last to adjudicate the amateurs' Roses with two good painstaking and upright judges, Mr. Wood and Mr. Perry. The first prizes fell in all instances most justly to Mr. Hedge. After I saw the name of Mr. Hedge affixed to class 1, I knew all his Roses in all classes; I knew them by the boxes, by the moss, by the mode of setting out, no less than by the superior growth of the Roses. I may say, from recollection, that he was only once nearly approached—viz., in the twenty-four singles, by Canon Fisher, of Sarum, our most distinguished western amateur. The very superior Roses in both lots stood in the relation of nineteen to seventeen, and in both cases the remainder were good. In country places the concealment of names is a farce. In London you do not want to conceal the names, because first-rate men are appointed, who, had they no conscience, know that the eyes of the horticultural and floricultural world are upon them. The "press" is there! The "press," in London, is a very good judge.

In conclusion, I think that professionals should never be secretaries of societies; that secretaries should not be allowed to accompany the judges, nor to entertain them; that the fairest judges in country places are the gentlemen's head gardeners; that getting distant judges, even leading men, by no means necessarily secures right and honest judgments. In all cases it depends upon the character of the men employed. I am for protecting judges, but I am not for allowing them to make capital out of the public property.

As regards objections made by competitors, they should be stated before the judges leave the show. No attention should be paid to them afterwards. Objections should never be made except where the erroneous or fraudulent judgment is palpable. Some allowance must be made for differences of opinion, or written rules for adjudication must be laid down.—W. F. RADCLIFFE, *Tarrant Rushton, Blandford.*

#### LA CONSTANTE AND SOME OTHER STRAWBERRIES.

I WAS quietly reading your Number of the 10th of January, when I was startled by the account H. Taylor, Esq., of Fencote, Bedale, gave of his plants of La Constante Strawberry. I at once posted off in search of my gardener and thus addressed him. "What do you think THE JOURNAL OF HORTICULTURE says of La Constante Strawberry? That the runners require to be potted and kept under glass during the winter; that it is to be feared it will not suit the climate of England." "Why, sir," he replied, "it is one of the hardiest Strawberries we have." "Exactly so," I said. "And now, can you tell me how many plants we have of this variety?" "Well, sir, there's that long row there. It contains more than 250 runners. Then there's in the border 50 plants I transplanted last September; and there's 90 plants in the Strawberry-bed which bore so well last summer. Besides these, I've a lot more in reserve, as I divided a few of the oldest plants last autumn. You've nearly 450 plants if all of 'em were counted up."

I state this in order to show that I have knowledge of, and acquaintance with La Constante Strawberry. I procured some plants of it years ago from that excellent fragarian, Mr. Nicholson, of Eaglescliffe, when he first sent it out. The summer following I was so pleased with the unrivalled flavour of the fruit, and the close compact habit of the plant, that I have caused it to be grown here extensively. I live in a colder climate than that of Bedale, and yet I am not aware that I have lost a single plant through frost or cutting winds. This variety of Strawberry has endured a

temperature of 12° below zero (for my thermometer placed on the ground at 9 o'clock p.m., on Christmas-eve, two years ago, indicated that extreme amount of cold), uninjured. Surely this is ample proof of its hardiness. It requires, however, good and patient treatment, for it puts forth its runners so late in the autumn that they are not able to gain size and strength sufficient to bear fruit the following summer. I will briefly state the mode of treatment adopted here with success.

In the autumn a trench is dug more than half a spit deep, a quantity of hotbed manure is spread in it and covered over with soil. Here the runners are planted 6 inches apart as soon as they are fit to be separated from the parent plants. They are watered if necessary from time to time, until they have rooted freely into the soil. About Christmas they are mulched with strawy manure, care being taken not to smother the plants. In the August following, another trench is dug about a spit deep. This is well manured, and covered over with soil to the level of the earth around. The yearling plants are taken up carefully with a trowel, and they are planted in this prepared ground in patches of two or three together, a space of 14 or 15 inches intervening between each patch. They are mulched again at Christmas. The following summer plants so treated have never failed to produce an abundant crop of first-rate fruit. The plants may be suffered to remain undisturbed for two seasons, when they should be again removed after fruiting into fresh ground well manured.

Carolina Superba and Crimson Queen receive the same treatment. All my other sorts of Strawberries yield good crops from runners the first year, they are then thrown away, fresh plantations being made yearly about the first week in August, if possible. I have not grown the Empress Eugénie, because Dr. Hogg in his "Fruit Manual," Second Edition, describes it as "Rather a coarse-looking and very large Strawberry, not remarkable for any excellency of flavour." I cannot see the advantage of growing these inferior varieties, Eugénie, Victoria, Oscar, and a host of others, simply because they are abundant bearers. Why sacrifice quality to quantity? Plant a row more of the finest varieties and the desired quantity is also attained.

The following sorts are the finest known, and they will satisfy every want:—British Queen, Carolina Superba, Crimson Queen, Eclipse, Emily, Frogmore Late Pine, La Constante, Rivers's Eliza, La Chalonnaise. This kind, however, is not required where the British Queen succeeds. To this list may be added Dean's Lord Clyde, Bicton Pine, and Elton Pine. The last-mentioned variety, though not remarkable for flavour, is the best late Strawberry. All these I either have grown or still continue to cultivate in my garden, and can safely assert that they are perfectly hardy, unrivalled in flavour, and excellent for preserving.

It may not be generally known that plants of new or rare Strawberries when first obtained from the nurseries, often fail to exhibit their true character, and appear to be of a tender and delicate growth. Here, both Crimson Queen and Frogmore Late Pine did not show to advantage until their third summer—that is, until I had raised plants from runners grown here. This may account for the supposed delicacy of La Constante Strawberry.—A FRAGARIAN.

#### GLAZING WITHOUT PUTTY.

I AM glad to be able to give your correspondent some little experience on the above subject.

First, I do not think it advisable, if possible, so far as horticultural erections are concerned, except on Mr. Cranston's plan. Why I think so will be stated hereafter.

Some two years since wishing to add about 300 feet of glass to my houses, I purposed doing it with rafters and glazing thereon, as I had seen similar erections apparently glazed without putty. I elected to try the plan and save trouble and expense, so I consulted my handy man with whom the idea took considerably, being new I suppose, and we (for I must have a hand in the downfall of putty), having the rafters fixed, began to lay the glass on, beginning at the bottom in the most orthodox manner possible, when, alas! after about half an hour's trial we were forced to give in and confess to being beaten thus far, for if we could fix

not a pane would remain fixed. John wished his rheumatic *pains* as unattached to him, as mine seemed likely to be without putty to my greenhouse. Now, the bright thought illumines our faces, it's as good as done. At it instantler, knock in a couple of tacks to keep up the first pane, and a little tin or lead hook for each succeeding one. Now, we go a-head, covering so much space that, with full employment at 1d. a-foot for glazing, I saw, or thought I saw, clearly how our Kelks and Cubitts had made such fortunes; and as to seed-selling, being summer time, I must confess I was rather false to my old love, and thought glazing without putty at 1d. per foot was the right thing after all.

Hark, what do I hear? "John, what are you doing?" "Nuthun, zur!" "What noise is that?" "Ony the glass a-rattling!" Yes, it was only the glass rattling, but that glass-rattling was on the roof of my new house, and I then thought, that if it rattled like that in such a trifling breeze, it would surely not only rattle but break with an ordinary wind. What's to be done? Why, of course, peg each pane down! How? With some nice V-shaped bits of tin. That's it! Off to Bill Smith's the tinman, who cut 'em to a tee, and not very long about it, and charged but a trifle for it too. Right we were, at least we thought so, so we inserted four of the tin wedges to each pane of glass (12 by 18's), and that day we heard no more rattling of glass.

Thus far, so good, and our glazing was again looking all right, but being about teatime, and as John could go watering, I thought a little cogitation on the subject would be valuable, so I weighed the *pros* and *cons*, and fancied the latter considerably the heavier, so I stopped the work to try an experiment as to how far glazing without putty would be watertight (supposing I had effectually settled the "wind-tightness"), so I poured water on the roof from a watering-pot with a moderately fine rose, about 4 feet above the glass, and the result was the glazing would not act at all, the water permeated under the edges of the glass and down the inside of the rafters into the house in a continuous stream, not in a drip. This was an experiment, and I must confess not at all satisfactory.

Glazing without putty was now at a considerable discount, so I found John another job for a day or two while I finished (to be sure it was done thoroughly), a small portion of the work with some thick paint, which I well worked in by the sides and on the rafters, and on the glass the width of the rebate, and which answered splendidly for the first or lowest pane of glass, but on the upper panes where each rested on the other it gradually soaked under each and down the under pane in a most provoking style, and no idea would suggest itself this time as a remedy, except to put on dry paint! and I concluded glazing without putty, except as aforesaid, was a failure for greenhouses.

Yet I did not give up, but had some thin putty made and placed it on the rebate of the rafters as in the first process of ordinary glazing, placed the glass on this, which with trifling pressure admirably filled up all the little spaces and did not run down the glass, pegged the glass down, used the little hooks and nails to keep each pane in its place as before, and laid on one thick coat of paint well worked into the rebate, and on to the glass about a quarter of an inch on each side. In a few days when a little "set," I took off the putty pressed out on the underside and gave the rafters a coat of paint well worked in up to the glass, and so far all was as perfect in every sense as glazing could possibly be, and was this summer perfectly air and watertight; but I would recommend an annual coat of paint, if possible, to such glazing, as the paint is apt to peel off the glass and look ragged and shabby. All who saw it considered it a good mode of glazing, as I did for some time; but two years' experience tells me that so far as I am concerned the old mode of glazing with putty is better, for this reason—glazing in the above mode must be done perfectly and in good weather, and painted as quickly as possible after placing the glass, consequently, the oil, whitelead, putty, &c., combine as it were into a kind of cement, the action of the weather still hardening it, so that I found it almost an impossibility to take out broken panes, clean as they should be, to replace with new ones without each time cutting away the wood-work, not to mention sundry panes broken from the extreme difficulty of "hacking out." Such difficulty I have rarely

found when they have been glazed with putty, as however hard the top may be, it by excluding sun, and with the moisture, &c., inside, keeps the putty under the glass, unless very old and dry, in such a state as to be easily scraped from the wood; therefore, I am again all right with my old love, and hope to avoid another putty trial, and that my experience may be some guide to your correspondent.—R. H. POYNTEE, *Taunton*.

Your correspondent can glaze without putty provided he gets glass made with the outside edges turned up—the glass to be in the centre of the astragals. The glass may be any length he chooses. Over the squares of the glass thus met he must have sheet iron bent, with small holes in the sheet iron to allow of small screws being fixed at regular intervals along the astragals, then small nuts to screw down the sheet iron as tight as he pleases. To keep the glass from slipping he must use small zinc hooks hooked both ways.—P. M. M.

### OBTAINING SUPERIOR PEAS AND CABBAGES.

THERE are few crops of more consequence than a good crop of Peas in summer and autumn, and plenty of good sound white Cabbage in winter and spring; for next to Potatoes, there are, in reality, no vegetables which are more general favourites, a dish of Peas forming as agreeable an addition to the table of the poor man as to that of the wealthy. Like the Potato, Peas require very little to make them palatable, whilst undergoing the cooking process, so there is no reason why the poor man should not enjoy them as well as the rich.

The season is now nearly at hand when something must be done in the way of providing for another year. I believe there are few that had anything to do with gardening last year, 1864, but found it a very dry season, and all vegetation suffered more or less, especially Peas. A few words as to how I managed to have plenty may not be unacceptable.

Having entered a new situation, I soon learned that plenty of Peas, early and late, would be called for, and being nearly Christmas, I began to examine the soil of the garden, to see if it had been trenched lately. To my disappointment I found the subsoil as hard as stone, not having been dug above 6 inches deep for many years. Now, common sense told me at once that Peas would not produce a satisfactory crop in such soil. What was to be done? I had no time for trenching, for other work was going on at the time, and I wanted a few Peas sown at once. I cut with a trench 18 inches wide and 2 feet deep, partly filled it with dung, well mixed it, and sowed my Peas. I served two rows this way, and two rows were sown afterwards, only digging the ground. The consequence was, plenty of Peas, but only in the rows where the soil was trenched.

The sorts sown were Daniel O'Rourke, in the rows trenched, and Dillistone's Early in the other two rows. I gathered from Daniel O'Rourke ten days earlier than from the Dillistone's. The former variety being strong and healthy, carried a good crop, while the plants of the latter were very weak, and very few pods were taken from them.

I followed this practice all the summer with other sorts, as Prizetaker, Glory, Champion of England, Hairs's Dwarf Mammoth, and Veitch's Perfection, with excellent results, but only from the rows that were on the ground trenched, mildew attacking the two rows on the ground not trenched, some time before they were in bloom. I had abundance of Peas all the summer and autumn, till the first week in November, when a slight frost came and cut my two last rows when in full bloom. If I had had materials for covering them, such as glass, no doubt I should have had good Peas in December.

I must not forget to say I mulched the rows with Mushroom dung, and short grass, and gave them a good watering twice a-week.

I served my Scarlet Runners the same way, and with the same success.

Before I put in my third sowing of Peas, the weather being so hot and dry, led me to believe that Cauliflowers, and early Broccoli, for winter use, would be scarce, also

that the Broccoli would be very small. I pricked out an extra quantity of Cabbage, in sorts, about five hundred plants altogether, and as I cleared away the early Potatoes, Cauliflowers, and early Peas, I planted Cabbages, keeping the plants alive by a watering now and then. Thus I had by October an excellent lot of good Cabbages. I had a six-light frame not in use, I pulled them up, taking the loose leaves from them, and laid them in leaf mould close together. The pit held the lot. I turned them back and cleaned them every three weeks, and I have now enough of good Cabbages to last me till April, and they are quite equal to spring-grown Cabbages. The sorts are Wheeler's Imperial, Enfield Market, and Nonpareil. I find Wheeler's Imperial keeps the best. This is a good practice where families do not care for Savoys.—H. COMLEY, *Gardener, The Hendre, Monmouthshire.*

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

The general preparation of ground for the spring crops having been delayed, no time should now be lost in forwarding the necessary digging and trenching, preparatory to the more thorough preparation of the soil before sowing-time. The principal causes of success in growing vegetables are a fine tilth, and as great a depth of earth as can be obtained without interfering with the subsoil, if the latter is of a sour nature. Clayey and retentive subsoils should, however, be forked over, loosening the ground to some depth. This will facilitate the passage of water from the roots, and by degrees the subsoil will become improved. There are but few vegetables which do not require a medium depth of 2 feet to grow in—some more, and hence the necessity of deep well-pulverised soil for their successful cultivation. To be effective the manure should be completely mixed with the soil to its full depth. For the present, therefore, the dung may be dug in in the process of trenching, and its thorough incorporation with the soil will be best effected when the ground is again worked over with the three-pronged fork. Respecting the application of manures to different soils, we may observe that for warm dry soils such as are of a cool nature, as cow or pig-manure, should be applied; horsedung will answer best in medium loams, while on stiff clayey soils a portion of ashes, road-scrappings, old mortar, or refuse of any kind, may be used in addition to ordinary manure. They will help to keep the land porous, and consequently assist the roots of growing crops to permeate the mass of soil. Old Cabbage ground, which has been under Sprouts since last August, will now become available for other purposes. Where plenty of Coleworts have been provided some of the latest of the July sowings will supply their place, and stand over for early Cabbage. Old Cabbage ground should be trenched and pretty well manured, as the Cabbage is a scourging crop. It is generally followed by a second sowing of Peas; the Peas in their turn are succeeded by Celery-beds, and this course prepares again for any of the Brassica tribe. *Cauliflowers* may be turned out of their pots, putting four strong plants under each hand-glass. See that the spring-sown do not "draw" if raised in heat. Let them be pricked-out betimes. *Spinach*, a small sowing may be made between the rows of early Peas.

### FRUIT GARDEN.

In the orchard get all planting finished as soon as possible, and stake and mulch. Remember to drain thoroughly. Nowhere is this advice more necessary than in the orchard. Although Apples and Pears are fond of adhesive soils, they will never prove profitable where water is allowed to accumulate. Examine all old or overborne trees. Many trees of this character may soon be recovered by applying manure at the extremities of their roots, and also by a good top-dressing.

### FLOWER GARDEN.

Wherever a high degree of keeping is required in the pleasure ground, nothing tends so much to their beauty as a close velvety lawn. It often, however, requires considerable trouble to secure this desideratum. On rich soils the coarser grasses prevail and are difficult to eradicate or keep under, while on soils naturally poor and which have been for some time under the scythe, the different kinds of mosses

are found to increase in a manner prejudicial to the better sorts of lawn grasses. As the present is the season when the mosses attain their greatest perfection, it will be found the best time to eradicate them, and a sharp-toothed iron rake or light drag will be the best implement for this purpose, working it sufficiently to bring up the mosses, which should be cleared off and the lawn left for some time, when a second operation may, perhaps, be necessary. In March sow thickly Sheep's Fescue Grass and Crested Dog's Tail, and apply a dressing of lime rubbish and fresh soil, or the latter and fine bone dust, which with occasional rollings to keep the ground firm will soon produce a good sward.

### GREENHOUSE AND CONSERVATORY.

A slight advance in heat may be made on bright days, but if cloudy skies intervene, revert immediately to decreased warmth, and let the humidity be in the same ratio. Those who are growers of Epacris, Correas, Leschenaultias, Polygalas, &c., will soon enjoy a rich treat in those charming tribes. Camellias at this time require abundance of water. Keep a sharp eye upon Ericas, Epacris, &c., that are pot-bound, some of these will require liberal watering. In addition to keeping the conservatory gay with blooming plants let the arrangement of the interior be occasionally changed, by grouping the plants somewhat differently and adding a few striking ones, as some of the hardiest Palms, &c., for effect. Orange trees in tubs are liable to be affected by a black fungus on the leaf, having the appearance of soot. This should at all times be thoroughly cleaned off. A little soapsuds, warm, with some sulphur mixed with them and applied with a sponge is a good remedy. Fuchsias may now be put in a little heat to start them for cuttings. Such as are wanted for early bloom may be pruned-in preparatory to disrooting them. Pelargoniums for early blooming will now require careful training. Thin out the shoots where too crowded, and tie-out the rest in the desired form. Fumigate on the first appearance of green fly, as it will save much after-trouble.

### STOVE.

The plants here will in general now require an increased amount of atmospheric moisture with a slight advance in heat. We prefer such advances to be for the most part on the afternoons of bright days, when the solar heat may be enclosed, and with a moist and wholesome atmosphere. Begin to repot Orchids, taking them exactly in the order in which they bud. Be sure that your material is scalded or half charred to destroy insects. Keep the plants well elevated and use plenty of charcoal in lumps of considerable size, fastening the whole at least so that the plant cannot be loosened by gentle shaking. Sphagnum or other moss pegged on the top makes a good finish, and is to be recommended in houses which are unavoidably deficient of atmospheric moisture. Syringe plants on blocks occasionally. Keep a sharp eye on insect-baits at this time.—W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

HERE the work done out of doors, owing to the snow, has been very limited. Removed on Thursday the covering from Cauliflowers, Lettuces, Radishes, &c., which had thus enjoyed a night of fully a week, and looked none the worse of it. As the weather becomes milder will give them all the air and light possible. With this object, washed in a thawing day the glass underneath which Potatoes and Peas are growing in pots. Gave also all the light and air possible to Asparagus in frame, and would introduce more, but that we are a little short, and also uncertain as to when it will be most wanted. Planted two frames of Potatoes, the beds having just a little bottom heat from tree leaves, planting rather thickly and putting the earth about them in ridges, so that some temporary things may have standing room between the rows. Finding we were deficient of material to make a slight hotbed just now for early Carrots, sowed some in boxes, so that they may be placed where there is a little heat, and be hardened off by degrees. We will, however, have a two-light box as soon as possible, as a bed of Forcing Dutch or Early Horn Carrots is one of the most useful things about a garden. We always think such quick-grown little dots have a sweetness peculiar to themselves. Re-

potted some nice little Cucumber plants that were growing in a hotbed of leaves. We have seen some of our old gardeners do this at the back of the frame, with a thick cloth covering themselves and the opening that the plants might not suffer—a rather different thing from carrying such tender plants all exposed in a sieve to the potting-shed. We choose a medium course. We had the plants under some little, wooden, bottomless boxes, but with a glass moveable top inside the frame. The plants were taken out quickly, placed in a deep basket half filled with warm leaves, and were then carried with a thick cloth over and round the basket to a warm stoke-hole shed, where pots and soil had been previously warmed ready for them, the pots all drained, soil in the bottom, &c., and warmish water all ready, so that the shifting was soon done, and the plants were quickly put back again by means of the warm covered basket, the bed being nicely forked over whilst the shifting was being done, in the close warm place.

In reference to the mischief accruing from sudden changes of temperature, a correspondent thus writes:—"What you said last week is all true about sudden extremes. I used, though only an amateur, to be very successful with Cucumbers. I was done one year, and I have always thought that my most successful rival had something to do with it. He noticed me taking some things very carefully from the bed into my little workshop, and then he came to talk about some long-winded story. I thought I had shut the door all right, but no, I left it open, and when I was at liberty my poor little plants were in a pitiable plight, and with all my coaxing they did no good afterwards. Thus I was regularly beaten through that good-natured chat." Well, it might be so—the leaving the door open was quite sufficient, without indulging in any uncharitable surmises. But why not have been straightforward, and told Mr. Fry to wait until you had done your job? The truth most likely was that you were determined your rival should not see your fine plants. Such hiding will soon be classed with the things that were, and when the knowing ones are caught at times they may expect to have the joke against them.

**Mushroom-beds.**—These have been producing heavily, and as we were obliged to sprinkle a little litter on the beds in severe weather, we have had it taken off, and swept the beds with a hair broom, so as to leave all clean and firm, then sprinkled gently any part that seemed a little dry, and we have no doubt that we shall have plenty more. At this season we prefer a little moisture in the atmosphere to much watering. A month or two hence water may be applied more freely if the beds are all dry, and some manure water from sheep or deer-dung will be more telling than clean water. Beat down firmly another piece that had been spawned about ten days ago. The beating firm is so far a preservative against woodlice. Do what we may we are always troubled with them as the spring comes on, and there is nothing for it but scalding and trapping. We have no doubt we take them in with the litter and the dung, for it is rare to be able to find one in the autumn after we have cleaned out the house.

Sudden extremes are also bad for Mushroom-beds. We have seen a bed covered up and producing well, all uncovered to gather the produce, and left uncovered and exposed until the bed was chilled, and the working spawn next to killed, so that when the owner went, expecting to gather a basket of fat juicy Mushrooms, he obtained nothing but little dots of brownish buttons, as tough as a blacksmith's apron.

We think we mentioned about double spawning an elevated sparred-bed, and it has done pretty fair on the under side, giving us some very large Mushrooms protruded through the spars. The bed altogether is about 15 inches deep. A little long litter was placed on the spars, then the turf with the grass side uppermost, all being made regular, with a little loam spread over the openings; on this a little of the dung materials for the bed, and on this spawn in little bits. The material was of such a nature that there was no danger of overheating, especially at the bottom. The bed above was treated just as beds are generally treated. Though thus Mushrooms can be had from both sides of a raised shelf bed, except for getting a dish from the under side on an emergency, we do not know if there is in the peculiar system a great deal to recommend it.

We have put in a little more material to help to make

another little piece of a bed on the bottom or floor of the house. The bottom part is chiefly fresh long litter from the stable: on that are placed some droppings that had been thrown together for a week. This would throw up rather too much steam in the house at this season, and, therefore, we cover it over with rough, lumpy, dry loam to keep down the moist steam. This soil is much better than wasting the manure by drying it too much beforehand. When people are scarce of material they must make the most of it. One of the finest beds we ever had was formed chiefly of old stable, with a casing over it of rather rotten dung; but for all that we prefer about equal parts of droppings and litter cut small, so as to mix intimately. At this season when droppings, unless they come direct from the stable, are apt to be too damp and wet, a little chopped straw, or dry litter chopped, will make it all in good condition. If even then the bed should be rather damp for receiving the spawn, a fine produce may be obtained by wrapping each piece of spawn in a handful of dry litter.

#### FRUIT GARDEN.

Looked over fruit-room, pruned a little in orchard-house, damped the Vines breaking, sprinkled Peach trees, and set Strawberry plants in bloom in the best positions we could muster for light. It is a great advantage to have a place for everything, but in these days how few can command such conveniences! Among the thousands who relish their early Strawberries how few there are who have a Strawberry-house, where the plants can be placed and remain until the fruit is gathered, as in the beautiful Strawberry-house at Enville. In all these places we reduced the temperature considerably during the storm, for what was the use of a high temperature when the days gave us nothing but fog and snow? The point of safety in all such cases is quite high enough as respects temperature, and the plants will be found strong and stubby to take the advantage of the sun and clear days when they come. The snow was rather more than a foot deep in this neighbourhood; as it is now melting fast, and filling the pools and reservoirs, it is also filling hearts with gratitude that they will not now be likely without water until the springs rise in the wells.

We are sorry that some amateurs with small greenhouses against the walls of their dwelling-house have suffered from the snow from the roof of their houses falling and crashing through the glass of the greenhouse. We had thus a score of small squares broken ourselves. The roof of the dwelling-house had been altered, and in attending to the roof of the mansion we forgot our own, and at night the slip of the snow went clear over the spouting and in through some of the glass. In all such cases of lean-to's where there is a high roof above them, some sort of parapet should be erected to prevent such an accident; or when a heavy fall of snow takes place, and there is a prospect of a thaw, a covering in the shape of shutters or thick canvass should be placed over the lower part of the greenhouse roof, as it will be easy to tell where the snow is apt to fall after it pitches past the spouting.

On steep roofs the snow remained only a short time; but on flatter roofs, as on the late vinery, it lay well, and thus gave a good protection to the Grapes, and we took care not to give as much heat below as to melt this snow whilst the frost lasted. The snow also protected all vegetables and young crops out of doors more effectually than could have been done in the sharp frost by any other means.

#### ORNAMENTAL DEPARTMENT.

Out of doors nothing has been done here, except clearing paths of the snow, and placing a good portion of it about the garden so that it would find its way to our reservoirs as it melted. If it had continued we thought of having a snow plough made for the roads and walks. For the former a good plough is formed of three strong planks, say 2 inches thick, 10 inches deep, two 8 feet long and one 6 feet long. The 6 feet forms the base of the triangle, the two others the sides terminating in a point, to which horse-power is attached; the handles are placed at the base. The three sides are strongly braced together, and if the snow is deep there is a heavy weight placed on the bracing or the box thus formed, or a man sits or stands there to keep all clear. For one or two men, for garden use, one about the third of the

size and much lighter is very useful where snowstorms are frequent.

In snowy days washed pots, cut tallies, made stakes, split wood, sharpened tools, put soil in warm places, picked over plants, regulated creepers and twiners, &c., washed stages, &c., and proceeded with potting, making a temporary bench in some of the houses to save the trouble of taking the plants out and bringing them back again in the cold. The top of the furnaces, and even the pathway of the Mushroom-house, are capital places for warming soils, almost as good as our amateur's hearthstone if the mistress of the establishment can be coaxed into permitting such encroachments on her domain.

*Calceolarias*.—Uncovered the pit of shrubby *Calceolaria* cuttings that had been made snug by the snow for a week. One light, we noticed, looked a little yellow, all the rest were quite green. The above pit-light will be all right after a few days of mellow light. The young things there had begun to grow, the green ones had grown less, and, therefore, suffered from darkness less or none at all. Let us again impress on our young readers the fact, that to withstand uninjured continued darkness the inside temperature must be so low that the plants shall have no inducement to elongate. If they do the seeming growth will become sickly and of a yellow tinge.

Any large plants saved, intended to bloom early in pots, should now receive their last shifting into good-sized pots, and into rich loamy soil well firmed round the balls. Such plants are useful for early blooming. To get late flowers from shrubby kinds in late autumn and the beginning of winter, either autumn or spring-inserted cuttings should be used, be turned out in May into a shaded border, no blooms permitted in summer, and the plants raised and repotted carefully in September.

*Herbaceous Calceolarias* sown in July and August should now be repotted and placed on a cool bottom near the glass, all the light possible given to them, and plenty of air when the external temperature is above 38°, and cold water used for watering when necessary. A good compost for this section is equal parts of good loam and very sweet decayed leaf mould, and half a part of sand. In April and May few things are more beautiful than a shelf or house of these pretty plants. For seedlings, pots 6 or 8 inches in diameter are quite large enough, but for approved kinds there is no limit to the size of the pot, or the size to which the plant may grow from a nice hotbed little plant in the autumn. When huge plants of these herbaceous *Calceolarias* are desired, it is always best to commence with a young plant, or a piece of an old one, but not to continue shifting an old plant that has bloomed. A plant with a single stem in September by frequent shifting all the autumn and winter may fill the largest pot before it blooms, if afforded all the little attentions it needs. Among these are plenty of sweet air, and a cool, moist, medium to stand upon, and if this healthy coolness is given there will be less need of tobacco smoke, though it should be used, and but moderately, whenever more than two or three green flies are discovered, supposing that these two are at once nipped up as soon as they are seen.

*Cinerarias*.—Watered the most forward with weak manure water. Potted younger ones and approved sorts, bearing in mind that whenever large-flowering plants are wanted the balls must not become pot-bound until a short time before you wish them to show bloom. This plant is more easily injured by frost, and is nearly as much averse to heat as the *Calceolaria*. Both will enjoy a great amount of sunlight and a very fair proportion of sun heat, provided the roots are moist and cool. Bottom heat, unless for particular purposes, is the abomination of both.

*Chinese Primroses*.—Watered with manure water those in full bloom. Shifted successions, and potted young plants. In dull, damp, foggy weather, when the soil becomes dry, avoid dipping water on the stem or the heart of the leaves, for gangrene or rotteness is apt to follow. This should be particularly avoided in the case of the double varieties. These, too, will also like a warmer temperature than the single, semi-double, and fringed kinds. In crowded conservatories the double kinds should stand elevated on reversed flower-pots, so that air and light may permeate all round them. If the least speck of damp or mouldiness appears at the collar or the base of the leaves remove it carefully,

using a small pointed knife if necessary, and fill the place and the surroundings with fine powdered charcoal, with a little powdered chalk or mild lime in it, and after a few days shake off the powder and use it again fresh bruised. These are useful for many purposes, as the bloom stands so well, which cannot be said of the single kinds, however beautiful and interesting they look.

As to *Camellias*, *Azaleas*, *Epacris*, and other hardwooded plants, we must refer to previous Numbers, and also as respects the forcing-house or pit; we have only to add, that as respects *Dielytras*, *Lily of the Valley*, *Roses*, *Deutzias*, *Rhododendrons*, shrubs, &c., all will now force more satisfactorily than they would have done before Christmas, and for all of them a slight bottom heat and a gradual increase of top heat will suit them well, bearing in mind that nothing is gained by sudden rises of temperature, and that Nature performs all her great operations gradually.

But we must leave all these to oblige by answering here the request of a lady as to *Lobelia speciosa*, and we do so by saying, that we would rather not decide whether the blue *speciosa*, or the lighter *Paxtoniana* and *Gordoniana*, and several others are best, as we really believe they are all good, and that a decided superiority in either will depend more on our own tastes and culture than on the direct intrinsic merits of the varieties; and then as to obtaining lots of these varieties, we decidedly say, for all small beds that are wanted to be first-rate and unique, and thoroughly alike in tint and habit, propagate every plant carefully by cuttings. Where vast quantities are needed, as for ribbon-lines or edgings, and strict shade is not so much a matter of consequence, then the best plan would be to sow the seed saved, and prick off and prepare as fast as possible until the end of April. The seedlings will cost far less trouble, and most likely they will stand through the autumn better. We believe the long lines of blue *Lobelia speciosa* at Enville were all raised from seed. You must now set about either sowing or propagating, according to the quantity you want, or better try both plans, and then give us the benefit of your experience, as we are all learners.—R. F.

COVENT GARDEN MARKET.—FEBRUARY 4.

There is a fair supply both of out-door and in-door produce. Apples are still plentiful and good, consisting of *Blenheim Pippins*, *Russets*, *Court of Wick*, *King of the Pippins*, *Stamford Pippin*, *Old Golden Pippin*, *Golden Knob*. Of good dessert Pears there is a short supply. They chiefly consist of *Beurré de Rance*, *Easter Beurré*, *Jean de Witte*, *Ne Plus Meuris*, *Colmar*, and *Passe Colmar*. Grapes have advanced in price, but are still very good. Some new ones may be had, but they are not equal to the old ones at present. Pines are scarcely sufficient for the demand; Oranges and Lemons abundant. Greens of all kinds, notwithstanding the late severe weather, are brought in quantities sufficient to meet all requirements. The usual imports from abroad are well kept up, and to the articles named in previous reports we have to add *Artichokes*. *Asparagus* is more plentiful; *Spinach* has advanced in price; of *Rhubarb* and *Sea-kale* there is a good supply.

## TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

FLORA will find an answer at page 15 of our Journal issued on January 3rd.  
DWARF CELINE ROSE STOCKS (J. B.).—Mr. W. Paul, Nursery, Waltham Cross, can give you the information you require.

EDLWEISS (M. A. E.).—Will some of our readers tell us what is the botanical name of the Alpine plant which has the above local name?

FAILURE OF CROPS (E. Fenzy).—On a sandy soil, having a sandy subsoil, full of couch grass and other weeds, and unmanured for nine years, no crop can be profitably grown. If there is chalk or clay to be had in your neighbourhood one hundred one-horse-loads of them per acre should be added to improve the staple. Save all your house sewage, and water your crops with it. Buy some guano, and put 2 ozs. of it to each gallon of water, and apply that to your crops. It will in your case be the best mode of manuring. No variety of Potato is specially adapted to such a soil—one will do as well as another, and any will do badly unless you apply plentifully one or other of the liquid manures we have named. The same observation will apply to Peas. Carrots might succeed on such a soil ifrenched two spades deep, a little manure turned in with the bottom soil, and liquid manure poured between the rows during the growth of the Carrots.

MUSSETT'S HOT-WATER APPARATUS.—I am sorry to say I can get no satisfaction with it; as yet I have not been able to warm the water. Have any of your correspondents succeeded with it? if so, I should be glad to know how they manage.—M.

CELERY—CUCUMBERS IN FRAME (W. B.).—A good red Celery for main crops is Cole's Defiance, and there is no better white than Incomparable. Cole's White is also good. Lairg's Mammoth is a good keeping Celery. As a rule red kinds of Celery keep better than white, being hardier, and not so liable to bolt—that is, to run to seed. About the last week in February make a bed of horse-dung, or stable litter that has been turned over once or twice to sweeten it, or get rid of its rankness. Let the bed be 1 foot wider than the frame all round, 4 feet high at back, and 4 feet in front; shake the hot dung, and beat it down with the back of the fork. On this place the frame, and put on the lights. In a week or ten days the greatest heat will be attained. A test stick, placed in the bed, will enable you to tell when to soil the bed, the proper time being when you can bear the stick in your hand without experiencing any sense of burning. When this is the case level the surface of the bed, and place about 3 inches of soil all over it, also half a barrowful under each light, exactly in the centre, in the form of a cone with a flattened top. The soil should be moderately strong turfy loam, but any kind of fresh loam will do, if not very strong. In about three days the bed will be ready for the plants; but where are they to come from? Perhaps some neighbouring gardener will be able to let you have a couple of plants, or accommodate a couple of pots in his frame, the seed being sown on or about the 5th of February. The sort we would grow for table use is Sion House or Carter's Champion, both very prolific and excellent Cucumbers for table. If you want size, Kirklees Hall Defiance, or Lynch's Star of the West, are large, fine-looking, and good for use. The plants being at hand, and having been stopped at the second leaf, plant them on the cone, and leave the top a little hollow, in order that the plants may be watered at planting. Water with tepid water, and always keep the soil moist; but do not give much at first, and, before May, always early in the morning. Admit a little air at back by tilting the lights there on fine days, and if you have a thermometer in the frame you may regulate the temperature to a nicety. In the morning, for the first fortnight, it should be from 65° to 70°, and when it sinks below the former degree, cover at night with mats, taking them off in the morning. Admit air at 80°, and close at the same, or a little higher rather than lower. After the plants become established, air may be given at 75°, and the frame shut up at 80°. When the roots come through the sides of the hills cover them with soil, leaving some in the frame twenty-four hours previously to be warmed; and as fast as they come through add more, until there is, all over the bed, 10 inches or a foot thick of soil. Stop the plants about a week after planting out, which will induce shoots, and spread these out evenly all over the surface of the bed. When they show fruit, stop the shoots one joint above the fruit, and this throughout the season, thinning out any shoots that have done bearing, and such as crowd those bearing. When the heat begins to decline, line the bed with fresh dung, and if you manage well you will have fruit in May, and onwards through the summer. In summer they will require water about every other day; and in July, if you add a little fresh soil, and lay some of the young shoots into the soil, they will do all the better. If you cannot obtain plants we would not make the bed until the middle of March, and then sow the seeds in small pots, plunging them in the bed after covering it with a few inches of soil, but not placing any in the centre just then. In a few days the seeds will be up, and when the rough leaves appear put the young plants in larger pots, watering carefully, otherwise they will damp off. When they have made two rough leaves nip out the growing point, and then is the time to place some soil in the centre of each light, and in a few days afterwards plant on the hills. The necessity for lining the bed will be increased, and the fruit will not be produced so soon by three weeks or a month. If you have convenience to make up a seed bed, and raise the plants, a bed 3 feet high will do, and you may sow the seed early in February, and so time the fruiting-bed that it will be ready for them when fit to plant out.

SELECT GLADIOLI (F. L.).—The following twenty are showy and moderate in price—viz., Adonis, Berenice, Brencleyensis, Ceres, Clemence, Duc de Malakoff, La Quintinie, Lord Raglan, Madame Binder, Madame Haquin, Mathilde de Lmdvevoisin, Napoleon III., Neptune, Oracle, Ophir, Penelope, Rebecca, Rembrandt, Vesta, Vulcaïn.

COVERS (Kenterian).—You can have a cover for the volume free by post from our office if you enclose fourteen postage stamps with your direction. A binder will charge 1s. for putting it on.

WALTONIAN CASE.—"A. C. C. H." wishes to know where he can obtain one.

PROTECTING WALL-TREE BLOSSOMS (J. E. W.).—You will have seen what we replied at page 95. Tobacco smoke will not injure Camellia buds. You keep the air of your greenhouse too dry.

HOT-WATER HEATING (W. Howard).—Your proposed house for Cucumbers and stove plants has some of the features of a house we gave a section of in our second volume (first series), only the Cucumber-house, or small stove, was heated by a tank without pipes, and the back house, separated from it by a glass partition, was a greenhouse instead of a stove. We instance the difference because, though the division of glass did well for ventilating the stove and Cucumber-house, it would not be equally effectual when the back house also was kept at a stove heat. We mention this because you do not speak of or show any separate means for ventilating the Cucumber-house. Neither do you mention the size of the two houses that form the general width of 20 feet; but we presume the Cucumber-house will be 8 feet, and the stove 12 feet in width, and we will act on this supposition in answering your questions. 1st, The dip of the flow-pipe through the tank will affect the circulation, unless there is an air-pipe fixed there at the lowest point, and that lower part or bend is above the height of the top of the boiler. Even then, if from an open cistern we lowered the pipe to the tank, we would not raise it at the farther end, but return it in the tank, and thence to the boiler; but there need be little difficulty if the bend in the tank is above the top of the boiler. 2nd, You will need two pipes in the tank for early Cucumbers. Of course the openings at the sides, to let out steam, must be under control. 3rd, For winter Cucumbers you would need three pipes for atmospheric heat. To have them about May two pipes would do. 4th, You would need at least four rows of pipes in the stove. If you wanted it above 55° or 60° in winter, five pipes would be safer and better. If you contemplated having bottom heat under the stage you would require still more, and then the pipes must be nearer the stage or platform, and not so near the ground as the section shows. Is not your platform for such a house too high? seemingly 4 feet 6 inches from the ground. This will place the plants mostly abreast of the eye. We should think from 2 to 3 feet would be better. 5th, Two pipes would be sufficient for the Peach-house, along front and one end, if it was deemed necessary that the Peaches should come in towards the middle and end of June; but to have them much earlier it would be advisable to have a third pipe, especially along the front. 6th, The two pipes would do very well for a late variety.

ROSES IN POTS (W. B.).—Roses may be grown in pots plunged in the open ground. Drain the pots well. Use a compost of turfy rich loam, and keep the pots plunged in coal ashes, in a sheltered yet open situation. They should be watered copiously when growing, and syringed overhead, except when blooming, in dry weather. In after years pot them in the latter part of September, or in October, and prune in March, cutting well in. Noisettes are too vigorous for pot culture generally, and very few Teas will do in your climate. *Tea-scented*: Gloire de Dijon, Abricoté, Bougère, Homère, Melanie Ozer, and Sombreuil. *Bourbons*: Souvenir de Malmaison, Queen of the Bourbons, Soubret, Coupe d'Hébé, Charles Lawson, and Paul Ricaut. *Hybrid China*: Général Jacqueminot. *China*: Mrs. Bosanquet, Madame Bréon, Madame Bureau, Cramoie Supérieure, Eugène Besunarnais, Marjolain de Luxembourg. *Moss*: Common, Reine Blanche, Vandaël, Frederick Soulie, Princess Alice, and Unique de Provence. *Hybrid Perpetuals*: Géant des Batailles, Duchess of Norfolk, Comte de Nanteuil, Jules Margottin, Lord Raglan, and Madame Vidot.

HEDGE PLANT—IVY FOR WALL (Idem).—You are rightly informed—nothing will grow so fast as Elder; but as a fence it is worth less. Nothing is so good as Thorn or Quicks; and you may have a fence in four years or so by planting strong Quicks. Ivy is best propagated by layers, and is also increased by cuttings. Strong plants would cover a wall 4 feet high in about three years, if planted a yard or so apart.

STANDARD ROSES (W. N. B., Northallerton).—Géant des Batailles, Madame Fritado, Madame Charles Wood, Madame Vidot, Sénateur Vaisse, William Griffiths, William Paul, Jules Margottin, Maréchal Vaillant, Comte de Nanteuil, Charles Lefebvre, and Caroline de Sansal. The above are all Hybrid Perpetuals. Your proposed planting is good, only dig them out deeply, and be liberal with manure. Too many plants in the circles are bad. Justice is not done the Roses. We do not undertake to furnish plans; we only criticise those sent to us. We will, however, see if we cannot make one to suit; but you ought to have told us what you proposed putting in the beds.

STOCKS FOR PEACH-GRAFTING (Idem).—We never met with Peaches on Cherry stocks that we recollect. For poor light soils it may at times be an advantage to graft or bud on the Almond or wild Peach; but that will not, in our opinion, conduce to the longevity of the tree. We should, for all outdoor work, prefer the Plum stock, and the one that made the most mop-like fibres we should like the best. We would not advise following the proposed plan except in the way of experiment. We would rather prefer common trees, and fresh rather poor soil. Owing to mistaking your letter for a few days, the bit of plant was much shrivelled; but we think it must be the Genista triquetra from your description. The pit for Vines will do very well, if the boards, coated over with tar, are so thoroughly dried and sweetened that no tar fumes are given off in the sun. If they are so given off, farewell to the health of your Vines. On this account we seldom use tar inside; even pitch would be better. Secondly, the pit will answer if it is not so deep as to keep the action of the sun from the roots. We do not, however, see the use of the chamber below the slate floor as tending to secure or husband sun heat. This it will do but to a small extent, whilst the open space will tend to keep the roots cool, whilst the tops are exposed to the greatest heat. Such a pit would do better if nearly all above the ground level, instead of being so much sunk. We are obliged by the explanations you have given of the proposed pit, and the one now existing.

HEATING CUCUMBER-HOUSE (Y. Z.).—For such a house, for winter produce, you will need about double the piping. The quantity of fruit must depend on the cultivator.

**BOOKS (A Constant Subscriber).**—The first book you mention is very good, but Hogg's "Vegetable Kingdom" is far superior to the other. (J. C.).—Hentfrey's "Rudiments of Botany," and Hogg's "Vegetable Kingdom" will give you ample instructions. They are both small in price.

**PLANTING VINES ON A FLUE (Delta).**—If we understand you aright, your flue, along the back wall, is so low, and so close to the wall, that you cannot well have a border of any sort there, without going over the top of the flue. If so, then, the covering the flue at each end, where you wish to plant a Vine, with a flagstone is a good plan, as it will give a little bottom heat. Three feet square is not large for a Vine, but it will do for several years. Place 6 or 8 inches of drainage over the flag, with a hole to let out extra moisture, and from 20 to 24 inches of good loam over it, with half a bushel of broken balled bones, and a bushel of horse-droppings to each place, nicely incorporated with the soil. After two or three years, if the Vines are continued, you will have to top-dress with rich manure, such as best cow-dung, or 4 ozs. of guano, or 1 lb. of superphosphate of lime at a time. A white Grape, planted in such circumstances, ought to be in two or three weeks before the Hamburgs planted in front, if you plant such kinds as the old Dutch Sweetwater (the earliest Grape), Buckland Sweetwater, or the Royal Muscadine. The two last are early Grapes, but not so early, in our experience, as the Dutch Sweetwater; but the latter requires more trouble in setting, but there need be no difficulty, if, as stated lately in "Doings of the Last Week," you just gently draw a dry hand over the bunches when they are in bloom, for several days in succession, and especially if you happen to get an hour's sunshine. These are all sweet Grapes, of what we may call the sugar and water kinds; but if you wish in addition a very rich aroma and Mu-cat flavour, we would recommend the White Frontignan as a free bearer and early ripener. To our taste, though the berries are small, it is far richer than any of the Muscats. We have mentioned none of the latter, because, under the same circumstances, the Frontignan will ripen from a month to six weeks before the earliest we have met with. We are glad our former answers were found useful. Such information makes duty a pleasure.

**STANDARD VINES IN POTS (Ruby).**—Vines can be grown as standards in pots by disbudbing the lower part of the Vine-stem, and leaving three or four buds at the top to break; but to keep them in continuous bearing two things are necessary—rich feeding and moderate cropping.

**ORCHARD-HOUSE IN SCOTLAND (J. Beckett).**—We quite approve of a flow and return pipe in such a house; but then that takes away from the character of an orchard-house and makes it one of a general character, as an orchard-house, properly speaking, should have no heat but sun heat. That extra heat must neutralise to a certain extent the low position of the house. In fact, with such heat to counteract vapours, the low position, 80 or 100 feet below the surrounding ground, ought not to have told much against the site if there was a free opening to the sun's rays. With fruit trees on walls the position would have been bad without extra protection, but in a heated house the position would tell less unfavourably. We think there must have been something besides the position. What about ventilation? A little at the apex might be necessary, or at least an opening at the apex over each doorway. Probably too much air was given at the sides at once. Though we would have liked a better site there seems nothing insurmountable to anxious effort.

**PLANTING VINES (Amateur).**—There is no objection whatever to planting the Vines in the middle of the house, either two together or one, and then train that one up and down. Some time ago we described a splendid viney at Wrotham Park, where the Vines are so planted. We have also mentioned several cases where, in such a house, with the border inside, the Vines were planted against the back wall, and also a yard or so from the front wall. It is a mistake to suppose that the mere place of planting is a matter of so much moment. Vines raised from a single bud are generally preferred; and if, instead of grubbing at 3s. 6d. per plant, you obtain strong plants at 5s., or even a little more, you will have made a better bargain than if you had paid 2s. for a small plant from a layer, the wood of which is likely to be poorly ripened.

**CINERARIA STEMS AND ACHIMENES DECAYING (An Amateur).**—We can only account for the stems decaying through drip falling upon them, or the supply of water being in excess of the requirements of vegetation, which will cause a soddened soil, and consequent decay of the roots, and ultimately of the stems and leaves. It may be due to something pernicious in the soil; but, without data on which to form an opinion, we can only hazard an idea of the cause. Send us a leaf or two, and part of the decayed stem, and these, with further particulars, may enable us to give a more decided reply. We may state that the temperature is too variable for Cinerarias. A temperature of from 45° to 50°, at this season, is quite sufficient for blooming plants; 65° from fire heat, is hot enough for a Pine Apple. The Achimenes are destroyed through bad packing, and their being subsequently kept in paper packets. You have done well with those remaining sound; and you would have done better had you placed them all in sand, or any light, dry, or but slightly moist soil, as soon as received. They may be kept in a dry place, free from frost, until potted. The cause of the roots rotting is their being insufficiently ripened before you had them, or their being kept in wet soil.

**HEATING BY GAS (Idem).**—We have known a house, 23 by 15 feet, economically heated by hot water, the heat being furnished by gas, it being kept at greenhouse temperature at a cost of 3s. 4d. per week; and the plants did well in it, besides being so cleanly in operation. This apparatus was Clarke's New Gas Hot-water Apparatus, and we have no doubt it would answer your purpose well. We also hear good accounts of Mussett's Patent Hot-water Apparatus, which will heat either with lamps or gas. Our practice is not to recommend dealers. Your best plan would be to consult those who advertise in our columns. Write to them, stating your wants, and they will furnish estimates, stating how much they would furnish the apparatus for.

**WATER FLOWING OUT OF SUPPLY-CISTERN (A Subscriber).**—Under such circumstances it would be as well if the supply-cistern communicated with the bottom of the boiler. We presume it now is in connection with the flow-pipe, and the pipe in the house to be heated is considerably below it. The air-pipe should be at the highest point of the pipe that goes round the house. We confess we do not quite understand your description nearly so well as a section of the boiler, cistern, and heating-pipe would have enabled us to have done. At present we would either take the pipe from the supply-cistern to the bottom of the boiler, or make the cistern double or more in size to allow for the expansion and contraction of the water.

**PELARGONIUM LEAVES SPOTTED (T. B. Thorpe).**—The leaves were spotted from an excess of damp air, and the parts spotted have had moisture on them for some time. You have no doubt done the best to remove the evil by giving an abundance of air, but this, in a cold frame, during muggy weather, is often the reverse of a source of dryness. Your only remedy rests in keeping the air drier by applying a gentle fire during damp weather, accompanied with air. Keep the leaves dry and they will not spot.

**WOODLICE (A Tormented Subscriber).**—We have nothing to add to what we said last week, page 97, on this subject.

**NAMES OF FRUIT (J. Sandy).**—2, Carlisle Codlin; 3, Very much like Flower of Kent; 4, Dumelow's Seedling; 5, Chaumontel. We cannot make out No. 1. It is an excellent Apple. (D. J.).—1, Wormsley Pippin; 2, Dumelow's Seedling; 3, Lewis's Incomparable; 4, Ord's Apple; 5, Augustus Pearmain; 6, Beauty of Kent; 7, Hunthouse; 8, Northern Greening; 9, Cockle Pippin; 10, Flower of Kent; 11, 19, and 20, Augustus Pearmain; 12, Scarlet Nonpareil; 13, Winter Hawthornden; 14, Margil; 15, White Nonpareil; 16, Norfolk Beefing; 17, Winter Queening; 18, Is not this the same as 5? 19, Golden Winter Pearmain; 20, Northern Greening; 21, London Pippin.

**NAMES OF PLANTS (A. B. C.).**—Your Fern is *Stenochlæna tenuifolia*. (Fred Silva).—Yours is *Asplenium palmatum cristatum*, but not quite so well crested as the specimen you mention. Yours may improve as it gains strength. (M. D.).—It is *Cyanotis vittata*, often called by gardeners *Tradescantia zebrina*. It is a trailing stove perennial of the natural order Spiderworts, and requires the same cultivation as the other stove species. It is a native of Mexico. Does well for hanging over the edges of suspended baskets in which the other plants are growing. (A. Broadclister).—*Erica colorans*. (C. B.).—*Eleusine indica*, a widely-distributed grass, found in warm countries of both hemispheres.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SUPPLY FOR THE LONDON MARKET.

I HAVE sometimes envied the writers in your columns; some, because they seem to have such well-regulated minds that they are always cheerful; others, because they seem well informed, and have quotations always ready; and another class, because they seem masters of the subject they treat on. I have doubted whether anything is requisite to justify an appearance in print beyond the last qualification.

On reading your article in last week's Journal I felt that many would read and doubt, because the consumption of poultry is large in London, and it is always to be had. It must then be produced, and it is produced. Living in the midst of it, I can speak positively on the subject—I see the whole process daily. Sussex is our largest poultry-producing county, so far as fowls are concerned. It not only is an article causing large returns, but it is important in the accounts of the railways; yet if you were to ask me to take you to any place where the operation could be seen on a large scale I could not do it; nor could I take you to any place entirely devoted to poultry breeding. The trade is in the hands of higglers. They attend all the markets, and they have besides regular houses where they call, and where they take all the fowls. There are many of them, and there is great competition among them. Many of these men have work enough to employ constantly two, and sometimes three horses. They do not breed, but they buy fowls, sometimes fattened and fit to kill, at others lean. These latter are taken home and fattened. It is not an uncommon thing for one to have thirty or forty dozen at a time undergoing the process.

These would be the most numerous stock I could show in a small space. These higglers in order to keep up a regular supply of some dozens weekly, travel hundreds of miles, and go twenty, sometimes twenty-five, miles from home to secure three or four dozens of good fowls. They are mostly bought in small lots of from twelve to eighteen, and it is not an uncommon thing for the higgler at a known good house, when he is taking away birds ready for market, to buy all the chickens he sees running about at a certain age for a fixed price.

It is thus the large supply of the London markets is maintained throughout the year. Those who breed the fowls are certain of a market for them, and can nearly tell beforehand the price they will make.—SUSSEX.

### POULTRY CLUB.

WILL you ask what the Poultry Club mean by the following passage in their circular?—"That the Club has for one of its main objects the discountenancing of the appointment of dealers as judges at any show." If Mr. Douglas is not a dealer, who is? Only last December he stated at Leeds,

that he had sold £300 worth of poultry last year to one lady. I, for one, shall not join the Poultry Club until I am convinced that the affair is not got up to satisfy the prize-list appetite of a few of the largest exhibitors. It may not be so, but a great many are very much afraid that such is the case. I give you my name and address as a guarantee of good faith.—A TIMID EXHIBITOR.

**PRICE OF EGGS.**

MR. GEYELIN is correct in his supposition, I do reside in the country. However, since I last wrote to you relative to the price of fresh eggs, I have been in London, and as I am in a position to supply a few hundreds weekly, I thought I would try to obtain a price similar to that quoted by Mr. Geyelin. The highest offer I had was exactly 5s. per 100 for fresh-laid eggs. At this time of the year they are worth more than that in the country, so I did not succeed in doing a trade. If Mr. Geyelin or any of your readers would be good enough to tell me where I could dispose of my produce at his prices, I should esteem it a favour.—C. S. J.

**PRESERVING EGGS.**

I SEE various plans mentioned for preserving eggs. The best and simplest of these plans I have not yet seen in your columns. Let me describe it. Take a half-inch deal board, bore in it as many 1½-inch holes as it will conveniently hold, then take four strips of the same deal, two of the length of your board, and two of the breadth, and 2 inches broad; fasten them to the edges of your board with sprigs, allowing half an inch of each to project above the board as a raised edge. You will then have an egg-crate, which will keep eggs good for an indefinite time if they have never been allowed to get wet. In my household they are kept in this manner from August to February, when eggs again become plentiful and good for all culinary purposes, except, perhaps, for bringing to the table as boiled eggs. A crate which I have just been measuring, is 40 inches long and 12½ broad, and I find it holds seventy-five eggs—viz., fifteen rows of five each. The half-inch projection above is to prevent any egg from rolling off.—T. G.

**POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.**

(Concluded from page 100.)

ESTIMATE of annual revenue and expenses for a poultry-breeding establishment with 3000 stock fowls:—

Profit from 1000 breeding fowls at 12s. each .....	£	s.	d.
Ditto from 2000 laying fowls at 13s. 6d. ....	1850	0	0
Extra profit from the sale of choice birds .....	500	0	0
Profit on the sale of 50,000 fat chickens at 1s. 6d. each .....	3750	0	0
Extra profit for eggs laid in winter (see page 16) .....	625	0	0
Or a nett profit of .....	£7325	0	0

This large profit on an outlay of about £3000 for buildings, fittings, and stock is explained in detail hereunder; and when it is considered that there exists an almost unlimited demand for eggs and poultry, that the sales are effected free of trouble and at a moderate commission by wholesale salesmen, and that the proceeds of the sales are remitted the day after the consignment, it must be from want of knowing these facts that so little has hitherto been done by capitalists in keeping one of the most useful but most neglected of domestic animals.

Estimate of revenue and expenses of one chicken, six months old, fattened for the market:—

REVENUE.		£	s.	d.	EXPENSES.		£	s.	d.
Selling price .....	0	2	6	Interest, rent, fuel, and sundries .....	0	0	3		
Feathers .....	0	0	1	Cost of chickens when hatched .....	0	0	2		
Manure .....	0	0	3	Food .....	0	0	9		
				Labour .....	0	0	2		
				Nett profit .....	£0	1	4		
							0	1	6
							£0	2	10

Chickens sent to the market at four or nine months old

will realise a proportionate profit, but the above may be taken as an average.

The expense for buildings, machines, hatching-appliances, stock, &c., does not exceed £1 per head on the breeding-stock; and allowing for wear and tear, and interest at the rate of 10 per cent. per annum, there will be a charge of 2s. per annum on each hen.

Estimate for one breeding-hen per annum:—

REVENUE.		£	s.	d.	EXPENSES.		£	s.	d.
150 eggs at 10s. per 100 .....	0	15	0	Interest .....	0	2	0		
24 chickens at 3d. each .....	0	6	0	Food, including share of cock .....	0	4	6		
Manure .....	0	1	0	Labour .....	0	2	0		
				Rent, fuel, sundries .....	0	1	6		
							£0	10	0
				Nett profit .....			0	12	0
							£1	2	0

Estimate for one laying-hen per annum. A hen kept from the cock will lay at least 180 eggs per annum.

REVENUE.		£	s.	d.	EXPENSES.		£	s.	d.
180 eggs at 10s. per 100 .....	0	18	0	Interest, rent, fuel, and sundries .....	0	1	6		
24 chickens at 3d. each .....	0	6	0	Food .....	0	4	0		
Manure .....	0	1	0	Labour .....	0	1	0		
							£0	6	6
				Nett profit .....			0	13	6
							£1	5	0

Epitome of the total estimated revenue and expenses of a poultry-breeding establishment, with 3000 stock fowls and 50,000 chickens per annum, as per preceding details:—

REVENUE.		£	s.	d.	EXPENSES.		£	s.	d.
50,000 chickens at 2s. 6d. each .....	6250	0	0	50,000 chickens, interest, rent, fuel, and sundries at 3d. each .....	625	0	0		
The feathers at 1d. each .....	208	0	0	Cost when hatched 2d. each .....	416	0	0		
The manure at 3d. each .....	625	0	0	Food at 9d. each .....	1875	0	0		
2000 laying-hens at 18s. .....	1800	0	0	Labour at 2d. each .....	416	0	0		
Chickens at 6s. .....	600	0	0	2000 laying-hens, interest, rent, and sundries at 1s. 6d. each .....	150	0	0		
Manure at 1s. each .....	100	0	0	Food at 4s. each .....	400	0	0		
1000 breeding-hens at 15s. .....	750	0	0	Labour at 1s. each .....	100	0	0		
Chickens at 6s. .....	300	0	0	1000 breeding-hens, interest, rent, fuel, and sundries at 3s 6d each .....	175	0	0		
Manure at 1s. each .....	50	0	0	Food at 4s. 6d. each .....	225	0	0		
From extra eggs during winter .....	625	0	0	Labour at 2s. each .....	100	0	0		
From extra price for choice birds .....	500	0	0						
				Total annual expenses .....	£4482	0	0		
				Nett profit .....	7326	0	0		
				Total annual revenue .....	£11,808	0	0		

From the above it will be seen that ample allowance is made for

Interest, rent, fuel, and sundries, which in the aggregate amount to .....	£	s.	d.
The food figures for .....	2500	0	0
The sum charged for labour will allow of an efficient staff of at least thirty hands, young and old, of both sexes .....	616	0	0

The revenue, on the other hand, will bear disappointment in any or all its items, and then leave an enormous profit in proportion to the capital employed.

The revenue from stock is represented in the aggregate by .....	£	s.	d.
From hatching chickens by artificial means .....	8800	0	0
From feathers .....	900	0	0
From manure .....	208	0	0
	725	0	0

**GENERAL PLAN OF BUILDINGS.**

A breeding-establishment on the above scale will require about four acres of land for the buildings. Six buildings, each 300 feet long, will contain 1200 poultry-homes; then a building at each end joining the six buildings will be used for artificial hatching, for stores, and all necessary offices. The cost of the whole will be about £3000. An uninterrupted covered

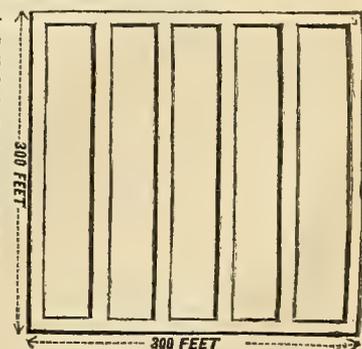

Fig. 24.—General Plan of Buildings.

communication with every part of the establishment is thus secured, and the whole forms a quadrangle.—G. K. GEYELIN, *Civil Engineer, London.*

### KELSO POULTRY AND BIRD EXHIBITION.

This was held in the Corn Exchange, Kelso, on Wednesday and Thursday, 1st and 2nd February, 1865. The following is a list of the awards:—

**SPANISH.**—First, R. Turnbull, Selkirk. Second, F. R. Pease, Darlington. *Chickens.*—First, W. McF, Aberdeen. Second, Miss B. Cuthbert, Causewayside, Edinburgh. Third, E. Brown, Sheffield. Highly Commended, J. Shortrose, Newcastle; I. G. Purk, Whitehaven.

**DORKING (Coloured).**—Cup and Third, Lord Binning, Mellerstain. Second, J. Gunion, Sandwith, Whitehaven. *Chickens.*—First, Lord Binning. Second, J. Steel, Kelso. Third, J. Bulman, Kelso. Highly Commended, A. Cameron, Mainhouse; Hon. Miss E. de Flahault, Tully-allan Castle.

**BEAUMA POOTRA (Any variety).**—First, Mrs. Gordon, Castle Douglas. Second, J. Shortrose, Newcastle. Third, Miss H. Scott, Anernum House. Highly Commended, Miss H. Scott. Commended, J. S. Kerse, Mounteviot.

**COCHIN-CHINA (Any variety).**—First and Second, J. Shortrose, Newcastle. Third, G. Tawse, Tillbrae House, Helensborough. Highly Commended, R. J. Chartors, Kalmouth (Cochin-China). Commended, Mrs. Dickins, Cornhill House.

**GAME (Any variety).**—First, W. Boyls, Beverley. Second, J. Fletcher, Stoneclough, Manchester (Black Red). Third, Easton & Mabon, Jedburgh (Duckwing). *Chickens.*—First, J. Fletcher (Black Red). Second, J. Perry, Netherby (Brown Red). Third, W. Boyls. Highly Commended, D. Broomfield, Kelso (Black Red). Commended, F. L. Roy, Nenthorn (Duckwing Game). *Single Cock.*—Cup, W. Boyls. Second, J. Fletcher (Black Red). Third, Mrs. Turnbull, Jedburgh (Black). Highly Commended, W. Easton, Jedburgh (Black Red).

**HAMBURGERS (Gold-spangled).**—First, A. Hatelie, Selkirk. Second, C. Anderson, Nenthorn. Third, R. Dickson, Selkirk. Highly Commended, R. Tate, Leeds.

**HAMBURGH (Silver-spangled).**—First and Third, Mrs. Craw, Jedburgh. Second, F. L. Roy, Nenthorn. Highly Commended, J. U. Somner, Jedburgh. Commended, F. L. Roy.

**HAMBURGERS (Gold or Silver-pencilled).**—First, J. M'Innes, Paisley (Golden-pencilled). Second, Miss H. Scott, Anernum House (Silver-pencilled). Third, W. Cheyne, Selkirk (Golden-pencilled). Highly Commended, J. M'Innes (Golden-pencilled).

**BANTAMS (Game).**—First, C. W. Brierley, Middleton. Second, D. Broomfield, Kelso (Duckwings). Third, T. Reid, Heaton (Brown Red). Highly Commended, W. Mabon, Jedburgh (Black Red and Game); F. L. Roy, Nenthorn (Black-breasted).

**BANTAMS (Any other variety).**—First, F. L. Roy, Nenthorn (Silver). Second, C. W. Brierley, Middleton. Third, T. C. Harrison, Hull. Highly Commended, A. Lindores, Kelso (Silver); F. L. Roy (Silver-laced); Lord Binning, Mellerstain House (Sebright).

**DUCKS (White Aylesbury).**—First, S. Swain, Bush, Jedburgh. Second, J. A. S. E. Fair, Gilliestongues. Third, J. Rutherford, Melrose. Highly Commended, R. J. Benson, Darlington; J. James, Samieston; Lord Binning, Mellerstain House.

**DUCKS (Any other variety).**—First, W. Hood, Edgerston Rig, Jedburgh (Rouen). Second, C. Hall, Bowmont Forest (Rouen). Third, Miss Lilly, Queenscairn (Rouen). Highly Commended, W. Edgar, Selkirk (Rouen); J. Patterson, Floors Castle (Rouen); J. R. Jessop, Beverley Road, Hull (East Indian).

**TURKEYS.**—First, F. R. Pease, Darlington. Second, T. L. Jackson, Bush of Ewes (Cambridge). Third, J. James, Samieston.

**GESE.**—First, S. Swan, Jedburgh. Second, F. R. Pease, Darlington. Third, Lord Binning, Mellerstain House (Toulouse).

**ANY OTHER VARIETY.**—First, C. W. Brierley, Middleton (Polands). Second, J. A. S. E. Fair, Gilliestongues (White Dorking). Third, Hon. Miss E. de Flahault (Creve Coeur).

**COTTAGE'S PRIZES.**—First, A. Henderson, Jedburgh. Second, Mrs. Noble. Third, J. Cairns, Kelso.

**SELLING CLASS.**—First, T. L. Jackson. Second, J. A. S. E. Fair, Gilliestongues. Highly Commended, W. Easton, Jedburgh; R. Tate, Leeds; A. Waugh, Helton; J. Robertson, jun., Kelso; Miss H. Scott; Miss Roy, Nenthorn; J. Rutherford, Melrose.

**SWEEPSTAKES (Dorking Cook).**—First, J. Henry. Second, T. Y. Craig, Kirkcaldy. Highly Commended, F. Anderson, Nenthorn.

**SWEEPSTAKES (Bantam Cook).**—First and Second, F. L. Roy. Highly Commended, M. Ballantine, Sprouston; J. Brooks, Kelso; A. Walker; I. G. Park.

### PIGEONS.

**CARRIERS.**—First and Third, H. Yardley. Second, J. R. Robinson, Sunderland. Highly Commended, R. Thompson; J. R. Jessop, Hull.

**TOMBLERS (Any variety).**—First, H. Yardley. Second, J. R. Robinson, Sunderland. Third, W. Bryden, Cumberland. Highly Commended, P. A. Renwick; F. Key; J. Bell, Newcastle. Commended, R. Thompson.

**FANTAILS.**—First, W. B. Van Haansbergen, Newcastle. Second, W. R. Park. Third, J. R. Jessop, Hull. Highly Commended, J. R. Robinson, Sunderland; Lord Binning, Mellerstain House. Commended, H. Yardley.

**JACOUBS.**—First, P. A. Renwick, Kelso. Second, G. Yale, Mellowlee. Third, W. Veitch, jun., Kelso. Highly Commended, Mrs. Craw, Jedburgh.

**BARBS.**—First, H. Yardley, Birmingham. Second, W. B. Van Haansbergen. Third, J. R. Robinson. Highly Commended, H. Yardley; J. Gow, Kelso. Commended, J. Mollison.

**TURBETS.**—First, J. B. Jessop, Hull. Second and Third, W. B. Van Haansbergen. Highly Commended, G. M. Byres, Northumberland; G. Yale; H. Yardley.

**ANY OTHER VARIETY.**—First, J. U. Somner, Jedburgh. Second, W. B. Van Haansbergen. Third, Mrs. Craw. Highly Commended, H. Yardley, Birmingham; Lord Binning.

**PAIR OF PIGEONS (Any variety).**—First, P. A. Renwick, Kelso. Second, A. Ormiston. Highly Commended, R. Porteous, Kelso; J. Brooks, Kelso; P. A. Renwick; H. Paterson, jun., Kelso. Commended, K. Porteous.

### CANARIES.

**DONS (Yellow).**—*Cock.*—First, J. Mather, Kelso. Second, J. Hervey, Jedburgh. Very Highly Commended, G. Trotter, Kelso. *Hen.*—First, J. Kemp, Galashiels. Second, J. Hervey. Very Highly Commended, A. Ferguson, Kelso.

**DONS (Buff).**—*Cock.*—First, J. R. Thomson, Hawick. Second, J. Bannister, Galashiels. Very Highly Commended, A. Ferguson, Kelso. *Hen.*—First, J. R. Thomson. Second, J. Mather, Kelso. Very Highly Commended, A. Ferguson. Commended, W. Balmer, Galashiels.

**BELGIANS (Yellow).**—*Cock.*—First, J. Aitken, Kelso. Second, W. Dryden, Hawick. Highly Commended, W. Tinlin, Galashiels. *Hen.*—First, W. Dryden, Hawick. Second, J. Kemp, Galashiels. Highly Commended, J. Aitken, Kelso.

**BELGIANS (Buff).**—*Cock.*—First, W. Tinlin, Galashiels. Second, G. Laidlaw, Galashiels. Very Highly Commended, P. Jeffrey, Kelso. *Hen.*—First, J. Kemp, Galashiels. Second, J. Marshall, Galashiels. Highly Commended, J. Stocks, Kelso.

**FLICKED DONS (Yellow).**—*Cock.*—First, A. Brown, Kelso. Second, A. Henderson, Kelso. Very Highly Commended, J. Crosbie, Kelso. *Hen.*—First, G. Laidlaw, Galashiels. Second, J. Mather, Kelso. Highly Commended, A. Ferguson, Kelso.

**FLICKED DONS (Buff).**—*Cock.*—First, T. Stoddart, Kelso. Second, W. Broadfoot, Portobello. Highly Commended, J. Mather, Kelso. Commended, J. Kemp, Galashiels. *Hen.*—First, T. Stoddart, Selkirk. Second, J. Kemp, Galashiels. Highly Commended, Miss Clay, Kerche-tera. Commended, A. Brown, Kelso.

**FLICKED BELGIANS (Yellow).**—*Cock.*—First and Second, A. Rutherford, Kelso. Very Highly Commended, J. Gibson, Gordon. *Hen.*—First, J. Gibson. Second, S. Smith, Gordon. Commended, G. Bennet, Kelso.

**FLICKED BELGIANS (Buff).**—*Cock.*—First, W. Dryden, Hawick. Second, J. Gibson, Gordon. Very Highly Commended, J. Creelman, Galashiels. Highly Commended, T. Lindsay, Kelso. *Hen.*—First and Second, J. Gibson, Gordon. Highly Commended, W. Hardie, Kelso.

**SWEEPSTAKES.**—First, J. Mather, Kelso. Second, J. Aitken, Kelso. Very Highly Commended, T. Stoddart, Selkirk.

**BEST PAIR OF CANARIES.**—First, A. Ferguson, Kelso (Dons). Second, P. Jeffrey, Kelso (Belgian). Very Highly Commended, A. Ferguson (Dons). Highly Commended, J. Mather, Kelso.

**JUDGES.—Poultry and Pigeons:** Edward Dixon, Esq., Gold Island; S. Brilby, Esq., Beverley, Yorkshire. *Canaries:* J. Forrest, Esq., Edinburgh.

### LONGTOWN POULTRY EXHIBITION.

JANUARY 25th AND 26TH.

**DORKING.**—First, — Hardie, Sorbie. Second, F. R. Pease, Darlington. Highly Commended, J. Jardine, Arkleston; J. Murray, Murray House. Commended, P. Scott, Netherby. *Chickens.*—First, Miss I. Hardie, Sorbie. Second, Miss Maxwell, Priors Linn. Highly Commended, Mrs. Graham, Braidlee. Commended, Miss L. Hope, Square.

**SPANISH.**—First, W. Hobson, Milnholme. Second, T. Franklin, Burnfoot. Highly Commended, F. R. Pease, Darlington. *Chickens.*—First, Miss J. Hardie, Sorbie. Second, — Gunning, Burnfoot. Highly Commended, Mrs. Graham, Braidlee; T. Musgrave, Longtown. Commended, G. Tait, Douglas.

**HAMBURGH (Golden-spangled).**—First, R. Dickinson, Selkirk. Second, R. Burrow, Longtown. Highly Commended, K. Holliday, Wheelbarrow Hall. *Chickens.*—First, T. Musgrave, Longtown. Second, R. Burrow. Highly Commended, Mrs. Ritchie, Selkirk; R. Dickinson, Selkirk. Commended, Miss M. Palmer, Dashwell Green.

**HAMBURGERS (Golden-pencilled).**—First and Second, F. R. Pease, Darlington. *Chickens.*—First, R. Burrow, Longtown. Second, F. R. Pease. Highly Commended, J. Towns, Longtown.

**HAMBURGERS (Silver-spangled).**—First, J. Hargreaves, Carlisle. Second, G. Tait, Douglas. Highly Commended, T. Franklin, Burnfoot. *Chickens.*—First, W. Cheyne, Selkirk. Second, J. Wilson, Crooked Holme. Commended, W. Benson, Longtown.

**HAMBURGERS (Silver-pencilled).**—First, T. Franklin, Burnfoot. Second, J. Smith, Canobie. *Chickens.*—First, J. J. Scott, Longtown. Second, Miss A. Little, Dickstree.

**GAME.**—First, John Brough, Carlisle. Second, James Brough, Carlisle. *Chickens.*—First, W. Gadders, Harker. Second, W. B. Thomson, Parcelstown. (Disqualified, cockerels' legs painted in each of the three pens, D. Brown, Lyne-side; J. Porter, Holmefoot.)

**ANY OTHER VARIETY.**—First and Second, F. R. Pease, Darlington (Gold Polands, Black and White Crests). Commended, W. Beaty, Longtown; J. Carruthers, Hornick Hill.

**GAME COCK.**—First, John Brough, Carlisle. Second, James Brough, Carlisle.

**BANTAMS (Game).**—First, J. Wilson, Longtown. Second, T. Davidson, Longtown. Highly Commended, F. R. Pease.

**ANY OTHER VARIETY.**—First and Second, F. R. Pease, Darlington.

**TURKEYS.**—First, F. R. Pease, Darlington. Second, Miss J. Hardie, Sorbie. Highly Commended, Mrs. Weightman, Sandbed; Mrs. Graham, Braidlee.

**GESE.**—First, F. R. Pease, Darlington. Second, Mrs. McBurney, Fauld Mill. Highly Commended, D. Little, Randalston; Mrs. Bell, Horsgills; T. Watson, Newbiggin. Commended, W. Bell, Carwinley Mill.

**DUCKS (Aylesbury).**—First, Miss Bell, Hirst. Second, Miss Maxwell, Priors Linn.

**DUCKS (Rouen).**—First, Mrs. Graham, Braidlee. Second, Miss Moffat, West-k-w. Highly Commended, Miss Palmer, Dashwell Green. Commended, F. R. Pease, Darlington.

**DUCKS (Any other variety).**—First, R. Jackson, Longtown (Wild). Second, R. Holliday, Wheelbarrow Hall.

### PIGEONS.

**CROPPERS.**—First, W. Cheyne, Selkirk (White). Second, A. Thomson, jun., Parcelstown (Red). Highly Commended, R. Irving, Langholm; Miss M. Malcolm, Milnholm.

**TOMBLERS (Almond).**—First, A. Thompson, jun., Parcelstown. Second, — Bryden, Netherby.

**TUMBLERS** (Any other variety).—First, A. Thompson, jun., Parcelstown, Second, — Bryden, Netherby (Black). Highly Commended, R. Irving, Langholm. Commended, — Bryden (Blue).  
**PANTAILS**.—First, J. Campbell, Langholm. Second, A. Thomson, jun., Parcelstown. Commended, — Bryden, Netherby.  
**CARRIERS**.—First, A. Thompson, jun., Parcelstown. Second, J. Tweddle, Longtown.  
**JACOBS**.—First, I. Cullen, Mount. Second, — Bryden, Netherby. Commended, R. Irving, Langholm.  
**ANY OTHER VARIETY**.—First and Highly Commended, J. Campbell. Second, — Bryden, Netherby.

**CANARIES.**

**BELGIAN** (Yellow).—Cock.—First, P. Little. Second, J. McKie, Longtown. Hen.—First and Second, J. Beeby, Carlisle.  
**BELGIAN** (Buff).—Cock.—First and Second, J. Beeby, Carlisle. Hen.—First, D. Marrs, Longtown. Second, P. Little, Longtown.

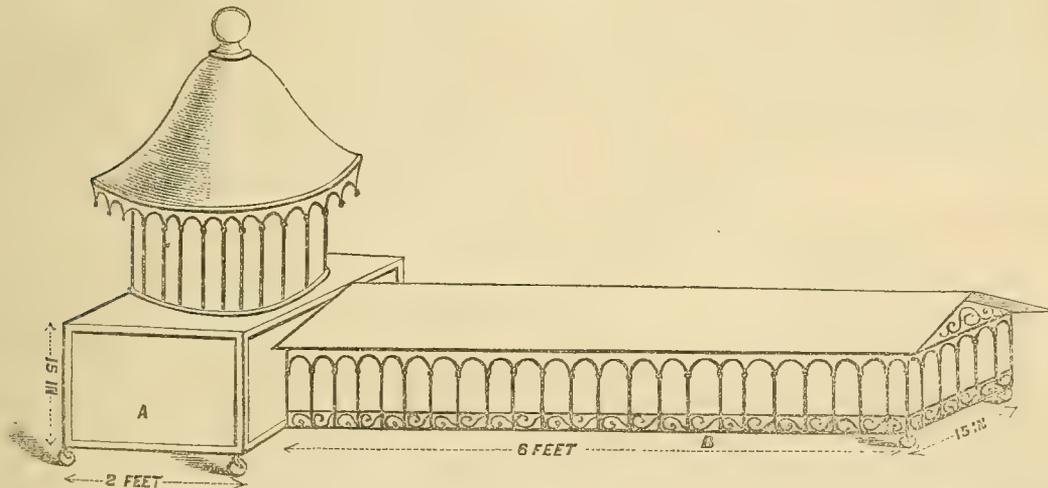

**SCOTCH** (Yellow).—Cock.—First, W. Davidson, Longtown. Second, G. McKie, Longtown. Hen.—First, J. McKie, Longtown. Second, P. Little, Longtown.  
**SCOTCH** (Buff).—Cock.—First, D. Marrs, Longtown. Second, J. McKie, Longtown. Hen.—First, W. Davidson, Longtown. Second, P. Little, Longtown.  
**COMMON CANARY** (Any colour).—Cock.—First, J. Beeby, Carlisle. Second, M. Little, Longtown. Hen.—Prize, J. Beeby, Carlisle.  
**MULE** (Any colour).—First, R. Jackson, Longtown. Second, T. Doughall, Carlisle. Commended, R. Crosslands, Carlisle; F. Anderson, Kirkpatrick-Fleming.  
**BEST BIRDCAGE**.—Prize, W. Davidson, Longtown. Highly Commended, J. Beeby, Carlisle.

**JUDGES**.—Poultry and Pigeons: R. Teebay, Esq., Preston. Pigeons and Canaries: John Armstrong, Esq., Carlisle.

**ORNAMENTAL HEN COOP.**

In compliance with the desire of your correspondent, "F. P.," for a design of a hen coop, and your offer to publish it if found suitable, I enclose a sketch which I believe combines all the requisites of a perfect hen coop—viz.,

1st, Free admission of sun light and air; 2nd, Shade and non-exposure of chickens to change of weather; 3rd, Easy supervision of the chickens by the mother; 4th, Being easily moveable to fresh ground.

A is a wooden box without floor, on rollers, and say about 2 feet square, and 15 inches high, with a circular opening at top, on which a wire gauze, with the projecting zinc cupola, are fixed, and which may be called the observatory

of the mother. B is a run formed of wire, the top covered with oil cloth or American cloth. This run can be detached in fine weather if desirable.

This subject alone would be sufficient for the foundation of a most interesting volume, but your Journal is too practical, and your space too valuable, to be so taken up: there-

fore, I will illustrate the necessity of a hen coop by one sentence—viz., "Maternal affection too often blinds discretion."—G. K. GEYELIN, C.E.

**THE BRADFORD POULTRY EXHIBITION.**

Most poultry amateurs felt a lively interest in the success of the Bradford Show, and the result was, not only a very large entry, but such general excellence throughout, as to form a theme for universal congratulation. In short, it was the uniform opinion of the three gentlemen who officiated as arbitrators, that taking a very close review of the whole, as classes, their experience did not call to mind a show which was open to so little exception. The prizes offered were liberal and numerous. Silver cups did, no doubt, not a little to secure this pleasing result; but another feature that as certainly tended as much as any to ensure public confidence, was the well-known fact, that a few of our largest poultry-breeders were "lashed to the helm," and under their care every confidence was entertained, not only of perfect justice being secured as to the awards, but also a feeling that the best and most judicious management might be depended upon, as to the welfare of the really first-rate specimens entrusted to the care of the Committee. Nor were the expectations of exhibitors disappointed, for the management of the Show was as faultless as possible, and our impression is, that many of the competing birds will actually return from Bradford in improved condition, rather than otherwise. Rough weather, accompanied by a fall of

snow, was the only drawback, and in all probability this did tend to lessen the number of visitors, but still the attendance was very much superior to the common run of such meetings. The Rifle Barracks in which the show took place, is a most suitable building for such a purpose, and affords an equalised light throughout, a feature so desirable at all such meetings.

The Spanish was a capital class, as evidenced by the fact that ten pens out of fourteen secured the favourable mention of the Judges. The Dorkings were equally good, but Lady Holmesdale's unapproachable collection was so triumphant as to leave only the less prizes to be competed for by her rivals. The Game classes were unusually strong, and the result was, the prizes were completely broadcast among some of the most noted Game fowl breeders; in fact, in these classes it was a very close run in almost all cases. The Brahmas were magnificent; and the Cochins classes were composed of most of the principal winners of the season. Capt. Heaton here still kept his mastery, though subjected to a number of very hard tests. Hamburgs, at Bradford, would be expected to be of first-rate character, the district being to a proverb, the locality of all others their own; they certainly well supported the prestige, for it re-

quired no small amount of forethought and experience to allot a silver cup in classes of all *Hamburgh* breeds competing, and, consequently, to the best pen. The *Golden-spangled* were the recipients of this much-coveted honour. We do not recollect ever seeing a better show of *Polands*, and the *Game Bantams* were as worthy of especial remark. The "selling class" was a downright success, many capital pens being entered at exceedingly moderate prices, whilst buyers were almost struggling to secure the most favourable specimens. The entry for this one class only was fifty pens.

*Rouen Ducks* were good, and the remainder of the *Duck* tribe were huddled indiscriminately together, forming, however, a beautiful class. Mr. John Jennison, of Belle Vue Zoological Gardens, Manchester, exhibited some exquisite specimens of *Carolina Ducks*, and the common *Teal*; *Aylesbury Ducks*, *Buenos Ayrean*, and a multitude of "cross-breeds," making a praiseworthy competition. Next year, we are told many of the classes of the *Bradford Show* will be sub-divided, and this meeting's present success justifies so doing.

The *Pigeons* were excellent, and attracted a very large amount of public favour, whilst a *Dog Show* attached to the Exhibition was filled to overflowing. Though late in beginning we do not hesitate to say, the *Bradford Committee* have now secured a standing for their local show unprecedented as a first success, and it must in such hands continue to increase in its prosperity.

We published the names of the *Judges*, and the list of prize-takers last week.

## A NEW CHAPTER IN THE NATURAL HISTORY OF THE BEE.

BEE COMMOTIONS AND QUEEN ENCASEMENTS.

(Concluded from page 104.)

THIRD question. Let us now consider the effects of introducing a queen into a queenless hive. Under this head I need scarcely bring forward cases in illustration. The fact is, there is no uniform rule that I know of, and the practical apiarian will find not a little dissimilarity of conduct on the part of the bees in such a case. We know it was *Huber's* opinion, that "if before substituting the stranger queen twenty-four hours elapse, she will be well received, and reign from the moment of her introduction into the hive." Greatly as I admire that distinguished and pre-eminent apiarian for his unrivalled knowledge of the bee, and for the general accuracy of his observations and experiments, I confess I have not found my experience on this point to coincide invariably with his; indeed, I am constrained in some important particulars to differ from his views as expressed in his letters, "On the combats of queens," and "Reception of a stranger queen." The German naturalists, *Schirach* and *Riem*, held diametrically opposite views from *Huber* on this subject. They thought it was the office of the common bees to settle the question as to the choice of queens, and to kill supernumerary ones; while we know that *Huber* maintained that not only virgin queens engaged in single combat, but that fertile queens also when placed together in one hive decided the question of ascendancy as between themselves after the same fashion—in short, "that the bees in no case ever sting a queen." We also know that the celebrated French naturalist, *M. de Reaumur* did not agree with *Huber* on some of these points, more especially in regard to the reception a stranger queen meets with, when introduced into a hive having a queen. *M. de Reaumur* affirmed that bees "having a queen they are satisfied with, are, nevertheless, disposed to give the "best possible reception to any female seeking refuge among them." In combating an experiment of *M. de Reaumur*, in which he had been successful in presenting a stranger queen to some four or five hundred bees which he had expelled from their native hive, *Huber* remarks—"To render such an experiment conclusive, it must be made in a populous hive; and on removing the native queen the stranger must be immediately substituted in her place. Had this been done, I am quite persuaded that *M. de Reaumur* would have seen the bees imprison the usurper, confine her at least twelve or fifteen hours among them, and frequently suffocate her. No va-

riation has occurred in my experiments regarding this fact." Here, then, we have very conflicting opinions entertained on this subject by these eminent men. Of course, great naturalists must be allowed to differ in opinion on some points, as great doctors do, but here the discrepancies are too wide, I think, to be the result of careful study and observation.

It is not my intention here to discuss this question at large, though my own views are decided enough. We must always bear in mind, that in operating upon bees, we frequently place them in an unnatural position, a position which, more or less, affects their instinct and dispositions, so that we cannot always calculate with certainty what the results in any particular case may be. *Huber* himself has admitted, that on one occasion a queen was stung in removing her from the centre of a cluster, but he thought it arose from pure accident and irritation caused by himself, and "that had he not interfered they would have been content with confining the queen, and she would not have perished."

My own opinion is, that in the great majority of cases in which the queen falls a victim to imprisonment, she is not stung, but succumbs through lengthened captivity, to inanition, privation of air, and ill usage. The truth is, a queen cannot be stung when densely surrounded by bees: hence I see in the very encasement itself a wise provision of nature to prevent such a result. It is in this way often converted from a proceeding, which at the first seems threatening and hostile, into one which ultimately becomes her very safety. For it is certain that in cases where the bees are so inclined, the queen emerges from a somewhat protracted confinement without the smallest injury; but if otherwise inclined the captivity is one of unsparing death. Hence when a queen is on any occasion encased, and it is desirable to release her, the utmost caution must be observed in doing so, for it may happen that just as you are in the act of divesting her of the last bee that encircles her, that remaining little vixen may in an instant, when all hindrances are removed, curve its body, and inflict a mortal wound. Caution and dexterity, therefore, are equally necessary in preventing such a contingency.

Bees are admitted by all to be creatures easily irritated, and highly pugnacious; but most apiarians, I think, err in viewing the queen as a mere passive instrument, having no likings or dislikings in whatever position you may be pleased to place her. Her dispositions, are, in fact, entirely ignored. This is a popular error, I think. Who can tell but the conduct of the bee may very often be guided by the dispositions of the queen? So that when a queen is introduced on any occasion to strange bees, her own want of submission may tend to a mode of dealing which might not otherwise be necessary. The lower animals are very quick in discovering in others of their species the different dispositions which affect their conduct towards each other, and when strangers meet amity or hostility may be the result, according as these dispositions betray themselves. Hence, therefore, at different times, I may introduce a queen to the same hive with different results. I was much amused during the past summer at the pluck and pugnacity of a young queen just begun to be fertile. She was removed from a *unicomb* hive for the purpose of being presented to a hive which had failed to rear a queen for themselves. After being confined in a little wire cage she was taken out and a single worker bee of the hive in question was presented to her. The bee examined the queen all round with its antennae, too curiously it may be, for pugnacious dispositions were evidently aroused in the royal breast, she being the first to attack, and a conflict resulted in which the queen, however, only came off second best. They were separated before any injury was inflicted on either side.

I said I differed from *Huber* in regard to results following the presentation of a stranger queen to a hive deprived of its own queen. True, it is safer in presenting a queen in such a case to allow twenty-four or thirty-four hours to elapse before doing so, and for this very obvious reason, that the bees will by that time have given over all hopes of finding their own sovereign; but the rule does not hold good invariably. I have found a queenless hive sometimes reject and kill a queen offered to it in such circumstances, even weeks after the loss; and, on the other hand, I have presented a queen successfully to a hive immediately after

depriving it of its own, and this, too, strange to say, without even an encasement. I shall narrate a case in point.

I deprived an observatory-hive of its queen to substitute a more youthful and prolific one. The substitution of the one was simultaneous with the deprivation of the other. I watched through the glass as a stranger queen ascended the comb, to see what was to be nature of her reception. She extended her proboscis to the first bee that encountered her, and was liberally fed by it. Her reception by others as they gathered around, though somewhat equivocal at first, was, on the whole, deferential and kind. Being struck with this indifference on the part of the bees, as to a change of queen, I thought of introducing a second queen, in order to test still further that indifference. This I did in about half an hour after, but this queen was immediately attacked in the usual way, and speedily surrounded by a dense cluster of ferocious enemies. I noticed a little commotion occurring in consequence of this encasement, and the first queen introduced also got a little excited, so that her timidity in traversing the comb caused some of the bees in her path to attempt to stop her progress. Seeing this I withdrew the encased queen, and the whole hive immediately became quiescent. I should mention that both these queens were reserve queens kept over with some few bees for experimental purposes. This case is, no doubt, an exceptional one; but it is on that very account I mention it. When in ordinary cases I have introduced a queen in such circumstances, a speedy encasement was the sure consequence. This does not always result, however, in the destruction of the queen. I have frequently succeeded in such cases without the aid, even, of any of those appliances generally resorted to. I shall give one instance in point out of many.

In the month of May last, the surviving Ligurian queen of two\* I had received from Mr. Woodbury (neither, I am sorry to say, prospered), was at the head of a thinly-populated hive. I took away this queen with the view of presenting her to one of the most thriving and populous stocks in my apiary. I first expelled the whole bees from this hive and deprived it of its black queen. After this I beat out the whole swarm upon a sheet, and allowed the bees to enter first an empty skep, and afterwards their own hive again, which they did with a joyful hum. At this moment when all was jubilee, I placed the Ligurian queen in the midst, and she entered in the throng unmolested. When all was housed and had settled down, however, the stranger queen did not escape observation. She was encased, but her captivity was neither severe nor protracted. She was very soon afterwards restored to liberty and honour. On a former occasion, and for a like object, I caused this same queen to pass through a similar ordeal, but allowed her workers to accompany her. All these were killed, and she alone escaped after a protracted encasement.

Of course, I have frequently introduced stranger queens to queenless hives without any opposition on the part of the bees, but I wish to show that bees are sometimes so capricious in all matters of this kind, that what suits to-day may not answer to-morrow.

I may here say that I have great faith in Wildman's method of dealing with bees—namely, by operating on their fears. I have in this way converted the most infuriated hive I ever witnessed, by a few manipulations, into the most submissive and docile, metamorphosed the most irascible soldiery, with every dagger ready to be unsheathed, into the most peaceful of subjects, which I could cause to march or counter-march without one rebellious murmur, and among whose moving masses I could thrust my uncovered hand without sustaining the smallest injury.

I do not know what amount of knowledge is possessed by German apiarians regarding the curious and interesting phenomena I have been in these columns discussing, and endeavouring to solve; but I see it is stated to be Dzierzon's opinion that "the queen bee cannot pass beyond the limits of the 'brood nest,' except at the risk of her life." This is a most extraordinary opinion to emanate from such a high authority in apiarian science as the distinguished Silesian

bee-master. I am certainly at a loss to account for it. It seems to me to be on a par with the opinion ascribed to Schirach in regard to foul brood, that an abnormal deposition of the eggs by the queen might originate it. In other words, that the reversed position of the eggs in the cells might give rise to a reversed position of the pupæ, "so that the young bees, unable to extricate themselves from their prison, die and putrefy." Every apiarian who studies the internal economy of the bee by the aid of his unicombe can disprove both these mistaken theories. Fancy may suggest one thing or another—an abnormal arrangement of eggs in the ovaries, or an erroneous oviposition; but it is quite clear that in whatever way the egg may be placed in the bottom of the cell originally, on its head or the reverse, granted only that it hatches and becomes a larva, and that that larva is found to assume an annular or curved position in the cell and retains that normal position till sealed—what influence, let me ask, could the original position of the egg in the cell have in such circumstances on the subsequent position of the pupa? Then, again, as to Dzierzon's theory of the queen being in danger when out of the "brood nest," how often may the queen be seen in the unicombe hive, as I have often watched her through the glass, in the remotest corner of it, away from the so-called "brood nest," as if on purpose to enjoy undisturbed, and with greater freedom, those intervals of repose which from time to time intervene, and which nature seems to require in the arduous work of oviposition? Often in such circumstances when the queen was enjoying her *otium cum dignitate* have I roused her from her royal slumbers by a tap on the glass to a resumption of her maternal duties.

But I must conclude. I know I have not exhausted this interesting subject, nor alluded to all its varied phases and aspects. I have, however, out of a great mass of materials, selected what I conceived to be most to the point. The question is, as I have already stated, intensely interesting. I have prosecuted it with great keenness. I do not profess to be confident in all the conclusions come to with respect to these curious phenomena in all their different aspects; but I have stated my views such as they are, and shall be ready to alter or abandon them when additional light shall make it manifest I have erred. It may be difficult, perhaps impossible, for us to get at the motives of the bees in every case when surrounding their sovereign. Perhaps this, like some other subjects of physical inquiry, will afford materials for new observations which will never be completely exhausted. But be this as it may, I agree with the following remark made by Professor Owen in his treatise on a more mysterious subject still—namely, parthenogenesis:—"The true and rational explanation of natural phenomena is usually the result of the exercise of common sense and careful observation."

One remark, in connection with this subject, I must be allowed to make before closing. We must not, I think, look to the conduct of the bee as being in all cases of this kind guided by unerring wisdom, more especially in circumstances where external influences of an artificial character are brought to bear upon it. The intuitive principle of instinct is no doubt sufficient to direct it in all ordinary emergencies; but when we see it in some abnormal instances or conditions depart from what we know to be for its true good, it is unfair in us to measure its doings by a higher principle of action which it does not possess. Reason, it must be remembered, is above instinct, and we are not to expect that the bee will, in all possible cases in which it may be placed, act up to the mark by which we would gauge its wisdom. The bee is confessedly a very irascible creature when provoked, and in such circumstances I have often witnessed it do many things exceedingly foolish, just as its master may, in similar circumstances, be seen doing things exceedingly foolish; but aside from provocation and artificial appliances, the instinctive wisdom of the bee as displayed in all its varied aspects is such as to draw forth our wonder and excite our praise, and thus to lead our minds to the contemplation of that Great and Wise Being who hath implanted in this tiny creature such wonderful instincts and dispositions. I say this in exculpation of the conduct of our little favourites where, in some such instances as those occupying our attention in these pages, they have, in my opinion, been visited with unmerited

\* Both these queens were, I understand, artificially reared in 1862. One of them bred a few small drones in March, 1863, but no drones at all in summer. In the following spring of 1864 she became a confirmed drone-breeder, and perished. The other produced no drones in 1863, very few in 1864, and died in January, 1865, a few days after the above was written.

censure, as if their instinct was radically at fault. I have always thought, and still believe, that when Nature is left to her own free and unfettered course—undisturbed and unmolested—instinct in the bee is a rudder which will be found almost invariably to guide it in a true and unerring course.—J. LOWE.

**BEEES DEAD IN THE CELLS.**

WHILST unable to look after my bees myself, a hive which required feeding was neglected, and I found all the bees dead. I wish to keep all the combs which are in a frame-hive, ready for a swarm in the spring, but I find several dozen bees have thrust themselves so far into the cells that it is impossible to remove them without crushing them. Would it be safe to leave them for the swarm to remove, or would it produce disease amongst the new occupants of the hive? and would not the labour of removing the bees be quite as much as building new combs?—A LADY BEE-KEEPER.

[We always extract the bees one by one with a pair of tweezers, such as are used by watchmakers, and although this is often a long and troublesome operation, we do not grudge our labour. We doubt if the dead bodies would produce disease, but the bees would be compelled to gnaw off the cells on either side of the comb and construct new ones.]

**SUPERIORITY OF LIGURIAN BEES.**

WILL you inform me in what the Ligurian bees are superior to the common bees, excepting being such great breeders? Are they generally preferred by those who have fairly tried both? I have ten stocks of the black bees, five of them are in the Woodbury bar and frame hives. One was an artificial swarm of May 7th, 1864, and gave me a super of 31 lbs. of pure honey on the 31st of July.—A. BROADCLISTER.

[Much greater beauty must also be conceded as an additional point in which the Ligurian is superior to the common bee. It must, however, be remembered that superior breeding powers argue greater powers of collecting honey, and really include every other good quality that can be named. We never knew any one who had once fairly established Ligurians in his apiary willingly return to the common honey bee.]

**TORTOISES.**

We have in the garden here two land Tortoises—the one a very old one weighing 7 lbs. 6 ozs., the other a very small one, which I received from a friend as a present about three months since.

They were both put in the same greenhouse and seemed to be doing quite well until about a fortnight ago, when from some cause or other the smaller one died. I should be obliged if you or any of your correspondents could inform me what was the cause of its death, as it received the same care as the older one has for the last thirty years; also, as I should like to polish the shell, how I am to get the body out of the shell to do so?

I should have stated the weight of it when living was 6 ozs.—J. PROSSER, Longford.

**AVOIDING RANCID BUTTER.**

ONE of your correspondents inquires about good butter-making. I have suffered from bad butter for three years, every autumn, and having four fine healthy young cows and a cleanly dairy-maid I thought it ought not to continue to be the case. My butter is now always good, and I have it up sixty miles from the country twice a-week. When the fresh 8 lb. arrives if there is any left of the 6 lb. which arrived at the beginning of the week, one is as good as the other. The whole secret is this: Have two cream pots, and let the dairy-woman stir her cream round the first thing when she enters her dairy, and empty the cream into the clean pot which was emptied and washed the morning before. This must be

done regularly every morning, and good butter will be the result, provided, always provided, the dairy-maid is clean with the dairy things. Mine are all scalded directly they have been used, pans, pails, prints, churn, &c., and placed in the open air, and rinsed with cold water before they are again used.

I may mention that glass is the best material for a cream-pot. A lump of salt should be kept in the cream-pot.—F. C.

RANCIDITY in butter is caused, in my opinion, by dead leaves eaten by the cows amongst the grass.—A FARMER'S WIFE.

[A gentleman informs us that he knows an instance where good butter never is obtained in autumn, and this is attributed to the cows eating the fallen leaves of oak and ash trees which fall on to the pastures from the trees around them.—Eds.]

**OUR LETTER BOX.**

KENDAL AND JEDBURGH SHOWS.—A first-class pen of Golden-sprangled Hamburgs exhibited at the above Shows has been exchanged in mistake or stolen. They were sent direct (or ought to have been) from Kendal to Jedburgh by the secretaries of the former Show, and a most wretched pair of mongrel-bred Hamburgs were returned from Jedburgh in lieu of the above, in a different hamper, but the proper direction label. Any exhibitor having received them in mistake will much oblige by writing at once to the secretaries, or the exhibitor, Mr. W. Cooper, Helmsley, York.

BRABHA POOTRAS (H. Leeworthy).—We were obliged by your communications, and, although you think they prove Brahma Pootras a pure breed, we think they support our opinion that they are a variety of the Cochinchina. You think the pea comb and more sunken eye are sufficient to prove a pure breed. We think they are no such proof, otherwise the Rose-combed Dorking might be considered a breed different from the single-combed. However, we have in recent Numbers fully stated why we think the Brahma Pootras a variety of the Cochinchina, and we refer you to those Numbers. Our opinion is confirmed, not changed, by the arguments and evidence elicited.

POULTRY CLUB (A Looker-on).—General innuendoes and sarcasms are not fair. If you have any specific charges, and furnish us (not for publication) with your name, we shall not hesitate at finding space for you. That the Club is a failure, and that a president and secretary resident in Ireland may not tend to renovate it, is probably true, but before we can allow it to be attacked in our pages we must be made aware of specific delinquencies.

KEEPING BANTAMS AND MALAYS ON THE SAME RUN (A. Broadclister).—You may run them together with impunity. Malays are not much in demand, but there is sale for good ones.

HENS LAYING SOFT EGGS (G. T. B.).—As some of your fowls lay hard, and some soft-shelled eggs, it is a proof the run provides all that is necessary. The Silver-sprangled Hamburgs are probably weakly-constituted birds. Give them castor oil, and put some preparation of iron in their water.

FOWLS FOR TABLE AND EGG-PRODUCING (Delta).—Spanish will do far better in confinement than Dorkings. Good ground oats are better food than thistle. Potatoes are not egg producers. The mixture is not a bad one; the fat is a good help. The grain enclosed is food for young chickens, but hardly good enough for adults. It is amusement for them to find it when it is scattered about. The cross between Dorking and Cochinchina makes a very useful fowl. If the produce are put together they do well; but the second use of either of the parents makes the breed incline so much that way as often to defeat the object sought. The cross between Spanish and Dorking is a bad one.

COTTAGERS' REMUNERATION FOR CHICKEN-REARING (Subscriber).—Your pay (1s for each chicken reared) is not good enough. Each old fowl would consume 8s. per year for food. A very common arrangement is to give 3d. per week for every chicken reared, if they are taken away at a certain age, or at the will of the owner. It must be borne in mind they are very troublesome and more expensive the first few weeks of their lives than they are afterwards. The cottager should have £2 for the keep of the fowls (one cock and four hens—Dorkings); and if the chickens were not kept after eight weeks, and were forty in number, 1s. 6d. each for the chickens.

LARGE SUPPLY OF EGGS.—F. W. Schroder, Esq., Frogmore House, Rickmanworth, wishes that "F. C.," to whom we replied in our Journal of the 21st ult., would communicate with him.

HIMALAYAN RABBITS (A. R. M.).—If you send us a letter in a stamped envelope, we will direct it, and forward it to "HIMALAYA."

AILANTHUS SILK WORM EGGS (F. C.).—If you write to Lady Dorothy Nevill, Dangstein, Petersfield, Hants, you will be furnished with a supply on reasonable terms.

**LONDON MARKETS.—FEBRUARY 6.**

**POULTRY.**

We have a good supply and a dull trade. We may now look daily for an improvement, as the House meets and London fills.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 45.9°, and its night temperature 31.0°. The greatest heat was 59° on the 16th, 1863; and the lowest cold, 2°, on the 17th, 1855. The greatest fall of rain was 0.51 inch.

THE AERATION OF VINE-BORDERS.

DO not know whether the aëration of Vine-borders has received that attention from Vine growers which its importance deserves. I fear it has not. I sometimes think that this question has not that prominence assigned to it which its merits demand, in the pages of THE JOURNAL OF HORTICULTURE, and similar periodicals. As an

element of success in Vine culture, I believe it to be of great importance, and in practice, wherever I have seen it judiciously carried out, other conditions being favourable, the results have always been highly satisfactory.

In the formation of Vine-borders, we should not forget that the Vine is an exotic, requiring to grow it successfully a much warmer climate than we have. To compensate for inferiority of climate, it is not enough that we plant it under glass, surround it with any amount of warmth, and treat it otherwise on the most approved principles. So long as we neglect to use means to raise the temperature of the soil around the roots, and place them in an equally favourable medium with the leaves and branches, so long will our success be limited, crippled, and unsatisfactory, the power of the Vine to mature a large crop of fruit greatly impeded, and the quality of that which it does produce inferior. This is, perhaps, more apparent in the northern than the southern portions of these islands.

By raising the temperature of the soil around the roots to suit the various periods of growth, the root-action is largely increased, the roots being able and ready to appropriate that food which is within their reach, and necessary for the healthful and vigorous development of the wood, leaves, and fruit.

In an aërated border comparatively few of the spongioles die during the winter; at all seasons they are to be seen a few inches below the surface in large numbers, ever ready to perform their proper functions when called upon to do so. In a cold, wet border, the reverse is the case, the roots being out of reach when wanted in the spring. The consequence is well known to most who have had to do with Vine culture.

Many of our best gardeners have in one way or other aërated their Vine-borders. The reason this has not become general, may be the very considerable expense incurred when chambered borders are formed. For successful aëration this is not necessary; the same end can be better attained by adopting other, more simple, and less expensive plans, and one that has been adopted here, and been in operation for a number of years, I purpose shortly to detail. One of the advantages of this plan will be apparent to most people at a glance—viz., the greatly

increased surface presented to the air, in passing below the border from the exterior to the interior of the house, and, consequently, the greater amount of heat absorbed—the principal, although not the only object to be gained by aëration, or subterranean ventilation. The atmospheric air is every fine day during the growing season from 10° to 25° warmer than the soil of an ordinary Vine-border not artificially heated. By taking advantage of this, and conducting it beneath the Vine-border, by a few openings outside and inside the house, causing it to pass amongst the drainage, which is used in almost every Vine-border in considerable quantity, a rude system of aëration might be secured, and found to work pretty well, particularly when 10 or 12 inches of stones or similar material have been used.

When new borders are to be made, it is generally necessary to concrete them, to prevent the roots from finding their way into the subsoil, which they will do, however well the borders may have been prepared, unless in some way prevented, and nothing is cheaper or more certain than concrete composed of lime and gravel. The borders of all the forcing-houses here have been concreted to the average thickness of 2½ inches, the surface of the concrete being 3 feet below the surface of the border when finished. The object which I have at present in view, will be best served by confining my description to one house.

The inside border is 30 feet by 16 feet. The external border is about 20 feet in breadth. At the outside of the border, and parallel with the house, a retaining wall is built with bricks on bed, strengthened by pillars every 5 feet, the whole rising to near the surface, the pillars having been built with openings in the centre 4½ inches square, and through these openings communicating with an air-drain below, running the whole length of the house, at the base of the wall, and acting both as an air and water drain. This drain is about 6 inches in width, and 10 inches in depth, being pigeon-holed on the side next the house. Four-inch drain tiles are laid across the border, 2 or 3 inches being left open at the joints, in parallel rows 10 or 12 inches asunder, and connected with the air-drain by the pigeon-holes, and with the interior of the house by pipes rising above the surface, beneath the hot-water pipes, passage, &c. The rows of tile-pipes lying on the concrete are overlaid with old slates, flat stones, &c., so as to leave as much open space as possible betwixt the rows, to be occupied with air currents. Above this covering a few inches of stones have been laid, finishing with very small ones, and about 2 feet of soil above.

After the month of March commences, advantage is taken of every warm hour, to admit atmospheric air below the border (the proper time to do so is ascertained by thermometers). This is done by opening the lids which cover the eyes in the pillars, keeping the front lights of the house shut, and opening the back ventilators, which at once sets a current in motion. As the season advances, and the weather becomes warmer, the aëration continues the greater part of the day, and in the

warmest months both day and night. Tiles and stones being good conductors of heat, they extract it rapidly from the slow-air currents, and gradually pass it to the soil above, thus improving the root climate of the Vines. And now for the result, which will be best seen by referring to the success of a few of the finer varieties of Grapes, but which are also more difficult to grow well.

The Muscat Hamburg, which is generally admitted to be one of the very finest Grapes in cultivation, is also, according to general report, considered to be one of the most difficult to manage. On its own roots here, in an aerated border, it grows and fruits as freely as the Black Hamburg, and why should it not, seeing that in some parts of America it grows so well? A friend writes me from near Baltimore, that "the Muscat Hamburg is a great favourite here, growing freely, and fruiting abundantly." Doubtless, the higher root temperature has to do with this. The Golden Hamburg, another Grape difficult to manage, also does well on aerated borders, but requires to be some years established before it swells its berries thoroughly. The Black Morocco thus grown, and allowed to hang till the fruit begins to shrivel, is not only a very showy, but a very delicious Grape, having a fine Damson flavour, very different from what it is as generally grown, being then considered a rather coarse Grape.

I shall only notice another variety, which is not generally well grown, but which luxuriates on an aerated border—viz., the Black Barbarossa. I cut it here in December, 1863, 8 lbs. 1 oz. in weight; bunch, berry, and bloom, all that could be desired, as symmetrical as the finest Hamburg, and when fully ripe not far behind it in flavour. When thus grown we never miss a full crop, the principal drawback is, that it requires from eight to ten months to mature its crop.

Other varieties succeed equally well. I only bring forward these important witnesses to assist in proving that much is to be gained by aerating our Vine-borders.—ARCHIBALD FOWLER, *Castle Kennedy, Stranraer.*

#### THE EXHIBITORS' LETTER TO THE COUNCIL OF THE ROYAL HORTICULTURAL SOCIETY.

It is with the deepest regret that I have read in the last Number of THE JOURNAL OF HORTICULTURE a letter from the exhibitors addressed to the Council of the Royal Horticultural Society. I say it is with regret, because I am certain the cause of horticulture must suffer from such a course of proceeding. I will place myself in the position of a disinterested looker-on, and, if you will allow me a corner in your valuable journal, attempt to reconcile, or, at any rate, diminish the objections offered.

The Council have evidently proposed a new, and, as it appears, objectionable scheme for the exhibition of plants for 1865. May they not have had some reason for making this great change? Now, it cannot be denied that, excepting for the pleasure of meeting so many friends and the general interest excited by so large a concourse of people, especially of the *élite* of the land, it has been a very general observation of late years, "How stale this thing is! We come to see the same plants exhibited by the same growers not only year after year, but at every and each exhibition of the season." It is well known in the horticultural world who will carry off the principal prizes. Mr. A may do so at one meeting, Mr. B at another; and why? It is often the circumstance of the condition of the plants, which even the difference of twenty-four hours may decide. It may be asked, Is there no merit in the cultivation of these perpetually successful specimens? Great merit is indeed due: great expense is incurred, and infinite labour and skill is required to produce these magnificent specimens of art. But after all what has this to do with horticulture? I am ready to admit that such well-grown specimens tend to the grandeur and effect of our exhibitions; but we must not forget that a repetition of the same things, whether of plants or any other objects of admiration, may at last lose their attraction. And here I think something may be said for the new scheme. Desirous of breaking through monopoly and monotony, the Council seem to have determined on holding more numerous and special meetings for certain

classes of plants, forgetting, no doubt, the necessary expense which attends these frequent exhibitions. The simple motive seems to have been to give a new feature to our old worn-out exhibitions, by no means adverse to the success of horticulture.

I now come to the day on which the exhibitions are to be held. The great objection has been made to Saturdays. I admit, for very many reasons it would not have been the day that I should have proposed; but it has been thought proper to try that day. The old Chiswick meetings were held on Saturdays. The Crystal Palace meetings have never, that I have heard of, been objected to by the complaining exhibitors. But this is not the question. What I would plainly ask is this—Has the Council of the Royal Horticultural Society, or the Council of any scientific body, the right to propose any scheme which they may think conducive to the advantage of that Society? I suppose no one will deny the power and right. Why, then, should the Exhibitors' Society take upon themselves in such defiant terms to refuse to exhibit? Surely it would have been more generous and courteous to have given credit to the Council for having reasons for making this change in the character of the exhibitions; and if objectionable terms had been proposed to the consideration of the exhibitors, it remained optional for them to decide whether they would send their plants or not, without entering into a combination not to exhibit.

The spirit in which the exhibitors have acted appears to me to bear something of a rebellious character. They seem to have placed themselves in a false position, and have as much as said, "We must have our own terms, or we will not exhibit." I am informed they even prepared, and actually sent, schedules to the Council, with their own value of the prizes affixed, and in their letter, after proposing a conference if the Council desired it, they, in the concluding paragraph of the same, declare themselves pledged not to exhibit. The insertion of an anonymous letter, however great the authority, does not strengthen their case. You will perhaps say, "What is to be the end of this rigmale?" The end is simply this, that if a mistake has been made on the part of the Council (and I am willing to allow they have made a mistake) then let the exhibitors do what becomes them as mortal men to do, who themselves are liable to make mistakes. Let them overlook the unintentional error on the part of the Council, let them banish all selfish feelings, and display that noble spirit of good will which is inseparable from the love of pure horticulture. However inconvenient the Saturday may be, let them choose the days fixed for the exhibition of their own specialities during the present season, feeling assured that some adjustment of the present disputed point may be made. Nor let it be forgotten there are many interests to be considered in the Saturday arrangement. There is a large proportion of Fellows, simply lovers of pleasure, gay meetings, and crinolinic exhibitions: Saturday is to them their day of holiday. Of the difficulties and inconvenience attending Saturday exhibitions I am quite aware; but as the exhibitors cannot alter the arrangements for 1865, will they from personal considerations stand in the way, if their lives be spared, of altering and improving the schemes for 1866?—F.R.H.S.

#### CHEROPHYLLUM BULBOSUM.

PERMIT me to ask the readers of THE JOURNAL OF HORTICULTURE, whether any of them can give a favourable account of the *Cherophyllum bulbosum*, or Turnip-rooted Chervil?

Unless others have met with greater success in their treatment of the seeds than has fallen to my lot, I fear the hope I had placed in these roots, as being a vegetable likely to be of great service in winter, will be disappointed.

It will be remembered that the introducer of these roots was Mr. William Paul, who exhibited some, I believe French-grown specimens, at the meetings of the Royal Horticultural Society. I am convinced very many, like myself, would be glad to receive any further hints tending to better success. It would seem that the secret rests in the seeds not germinating. I have tried a variety of ways having this object in

view. I have sown the seeds, and treated them precisely as advised, and I have soaked them in the autumn in warm water, placing them afterwards in sand kept moist all the winter. I have also sown these in the open ground in spring, and some upon hotbeds. The only success, however, I can note is, about eight roots produced last summer upon a south border. Over these seeds, however, I placed early in April a two-light frame, the plants came up in May, and the specimens produced were very large.—WILLIAM EARLEY, *Digswell.*

### WINTER-FLOWERING PLANTS.

THE subject of winter-flowering plants is one, I think, which ought from time to time to be brought prominently forward, and the difficulty is as important as any, in a decorative point of view, that a gardener has to contend with. During the dreary months of winter, when our gardens are fast bound in the grasp of the icy king, and everything of a floral character, except, perhaps, the Christmas Rose, has succumbed to his severity—when the trees are leafless, and the earth covered with a carpet of snow; while the winds are howling through the bare branches of the skeleton-like forms which occupy our plantations and shrubberies, how pleasant to be able to walk to and fro in a nice genial temperature of some 50° or 55°. What a contrast to the outside desolation will such a warm greenhouse afford, sheltered from the nipping wind, and surrounded by all the beauty and loveliness of spring. How pleasing at such a season to promenade amid flowers of every hue, hanging like tassels, or standing like sceptres, or curving gracefully to meet your gaze, some of them filling the air with sweet perfume, until one could fancy oneself transferred to some fairy land. Surely the accomplishment of such a result is worth an effort; worth an occasional column in your paper; and worth all the accommodation necessary to secure it: and last, though not the least, deserving of a good show-house in which to enjoy the display.

Many plants flower naturally at that season, others by special treatment can be induced to do so, while others, again, by a little forcing can be brought in about the same time. Lists of such plants as flower through the winter months would very much assist in the attainment of this object, and in order to make a beginning in this direction, I send you a list of those that have flowered at this place during the months of December and January. Part of them have flowered in the stove, and part in the conservatory; but in a good show-house kept at an intermediate temperature, such as indicated above, I have no doubt that the whole would do well during the time they were in flower. I have purposely excluded Orchids from the list, in consequence of the letter published by you a short time ago, from Dr. Ainsworth's gardener, Lower Broughton, giving the names of those belonging to that lovely tribe that have flowered with him through the winter; but I cannot help mentioning that little gem, the *Goodyera discolor*, with its dark velvety leaves, and pure white flowers.

In the stove we had *Begonia insignis*, a fine variety; *B. nitida*; *B. Ingramii*; to which might be added *B. lucida*, white and very free; *Ardisia crenulata*, both varieties, more for their red and white berries than their flowers; *Eranthemum strictum* and *E. pulchellum*, the latter, a beautiful blue, coming into flower just as the former is over; *Euphorbia jacquiniæflora*; *Poinsettia pulcherrima*; *Hæmanthus albus*, a curious but pretty Cape bulb; *Heterocentrum mexicanum* and *H. roseum*; *Justicia speciosa*, very beautiful and lasting a long time; *Thysanacanthus rutilans*; *Pentas carnea*; *Sericographis Ghiesbreghtii*; to which might be added *Goldfussia anisophylla*; *Manettia bicolor*; *Geissomeria longiflora*; *Aphelandra aurantiaca*; *Centradenia rosea*; and *C. floribunda*.

In the conservatory, of course *Chrysanthemums* take a prominent place in December; then *Camellias* follow through January, or earlier, according to the treatment they receive. *Primulas* (Williams's strain), are very fine. The Fern-leaved variety is a pretty addition. Besides these are *Epiphyllum truncatum*, varieties violaceum, purpureum, salmonum, magnificum, and cruentum; *E. Russellianum*, varieties rubrum and Saowii. The varieties of *Russellianum* succeed those of *truncatum*, and thus prolong the blooming season.

Of *Epacris* there are many sorts, *Lady Panmure* and *Viscountess Hill* deserving special notice; also *Erica mutabilis*, *E. colorans*, *E. melanthera*, *E. scabriuscula*, and *E. Lambertiana rosea*; *Corræa picta superba* (scarlet), *C. delicata* (blush), and *C. magnifica* (white); tree *Carnations*, *Linum trigynum*, *Monochætum ensiferum*, *Luculia gratissima*, *Daphne indica rubra* (powerfully scented), and *Solanum capsicastrum* for the sake of the berries.

To these must be added *Hyacinths*, *Narcissus*, *Tulips*, *Crocus*, and *Snowdrops*; forced *Azaleas*, especially that beautiful variety called *amœna*; choice *Rhododendrons* of the earliest varieties; *Acacias oleifolia elegans* and *rotundifolia*. If any of your correspondents can furnish the names of any others that flower through the winter, I, and no doubt many other of your readers, would be glad of the information.—THOS. JONES, *Rusholme, Manchester.*

### EARLY KING POTATO—GENERAL CULTURE.

"E. W." asks for information respecting this Potato. In the first place, he is mistaken in the name. It was named the King Potato, or King of the Flukes, being a seedling from that kind. It is a second early, not an early one, a great cropper, and very handsome, having a beautiful straw-coloured clear skin, but, as "UPWARDS AND ONWARDS" says, of all shapes, still fit for exhibition, being beautifully equal. As you take a root up, part of the tubers will be good-shaped Kidneys and part quite round, but there will be more Kidneys than round ones.

I have taken prizes with this kind at several shows for early round, early Kidney, late round, and late Kidney; and after the show the Judges would hardly believe me the tubers were all one kind. The first year I grew them they took the first prize everywhere I sent them, including Birmingham, the International Show at Kensington, and at the Crystal Palace, so we may safely say it is the best exhibition Potato grown.

The heaviest twelve I ever grew weighed 12 lbs.

It is a good eating Potato if grown upon a light soil. I have seen it waxy, with a cavity in the centre, when grown upon a heavy or damp soil.

It was raised by Mr. Spencer, who a few years ago lived at Hartshill, near Atherstone. The same gentleman raised the Queen of the Flukes, the best late Kidney grown.

I obtained a few of each kind from Mr. Spencer, and found them both first-rate. If "E. W." will send me his address I shall have great pleasure in sending him a few Kings for trial. They are as important to the grower of Potatoes for exhibition as Charles Lefebvre Rose is to the Rose-fancier.

I am surprised that "E. W." uses manure and manure water to his Potatoes; I never use either, and take many prizes. Try this year half your Potatoes with manure, and half without. I will back those without for size and quality. I always select a piece of ground that has been highly manured the year previously for some green crop, such as Cabbage, Kidney Beans, or Greens, and dig two spades deep some time in the winter, or any time before frost, the earlier the better, keeping the top spit at the top, for clay or gravel is of no use. The early kinds I sprout in boxes, but only allow one top or sprout on each set, for to grow large Potatoes there should only be one top. The late kinds I cut till there is but one eye or set.

Eighteen or twenty inches between the rows I have found wide enough for early kinds, and from 2 to 3 feet for late ones; indeed, I have one kind that requires more than 3 feet, the top is so large. It is a scarlet Potato.

After growing this year and last forty-seven kinds, the following proved the best:—Sutton's Racehorse, first early Kidney; Leamington Kidney, rather similar to Jackson's Seedling, first early, all shapes like the King's; King's, second early; Dalmahoy, round second early; Red Regent or Red Holland, round late; Queen's, or Queen of the Flukes, late Kidney.

I dare say "E. W." will hardly agree with me about the manure, but let him try a few without it. Of course, if you plant a field with Potatoes, and that field is in a poor state of cultivation, manure must be applied; it should in that case be put on in November, and the soil well worked. A Potato only requires the soil to be moderately rich, and

luriance in the top is a bad sign for the crop. Again: Potatoes grown with manure do not keep well. I have seen clamps with every Potato rotten in them, and the people said they were a bad sort, when the adjoining clamps of the same sort grown without manure were all sound.

I dare say before now "E. W." has entered twelve Potatoes for a show, and put them up for a time in a safe place till the show morning, when to his amazement half or all of them had become rotten. If he will keep the manure from them in the garden this will not be the case, and his Potatoes will be larger.

The best way to keep them for an exhibition is to put them in damp drift sand. This is the best thing possible if they are a little green from exposure.

I have not found any advantage in planting very early. The end of March or beginning of April is quite soon enough for the general crop. Hay is a capital thing to keep the frost out, but I like mine to keep under the ground till the frosts are gone. It is very important to mould them up well when the soil is dry. The only manure I have found to suit the Potato is rotten turf.—J. CHOYCE, JUN., *Harris Bridge, Atherstone.*

### VINES IN POTS AT COMBE ABBEY.

Your correspondent "P. M." has been rather too sharp upon me. Vines may be fruited in the time he names, and I wish I had no more difficult problem to solve than that.

The Vines which "P. M." saw here in 1863 were grown partly through necessity. In 1862 we were engaged in pulling down the old range of houses and putting up the new. During this transition some eyes which I had struck were but indifferently cared for, and at the end of that year were nothing better than mere straws. Early in the spring of 1863 about two dozen of these were cut back and put into heat; by June they had made very good growths, and thinking it a loss of time to grow them on for fruiting during the third year, I resolved to adopt the plan of Mr. Hardy, for which he drew upon himself at the time so much odium for tampering in such a manner with his permanent Vines. The Vines had run up about 6 feet, and before showing symptoms of ripening, they were stopped, denuded of all leaves and laterals, tied closely down to assist their breaking regularly, and continued in the same heat. They soon broke their latent buds, showed fruit freely, and all went on pleasantly throughout the autumn. The result was that which "P. M." saw, and to which he has been pleased to call attention.

Last year I had a little pit, 40 feet by 12, of pot Vines, in which we fruited thirty-eight Vines, each bearing from three to six bunches. Altogether there were 150 bunches, averaging in weight from  $\frac{1}{2}$  lb. to 1 lb., and some of them 1 $\frac{1}{2}$  lb. per bunch. The Black Hamburgs maintained their usual good character; but if I may be allowed to give a preference to Black Grapes (but, in fact, I claim it), I must decidedly give it to the Trentham Black for magnificence of bloom, equality of bunch and berry, and every other good trait desirable. I was also very much pleased with the Golden Hamburg, which had the same treatment as the others in this pit.

Much has been said about finding a stock for the Barbarossa. To me this seems about as ridiculous as "Diogenes with a lantern looking for an honest man." Why not grow it on its own roots? Whether the bunches grown here during the past season were a freak of nature or of mine, it matters little, the bunches were grown, and the Vine was on its own roots. I here give the opinion of the Barbarossa Grapes in the words of my employer:—"The Barbarossa Grapes were very good, very sweet, and thin-skinned. Decidedly better than Lady Downes', although the latter is decidedly a good Grape."

I take this opportunity of thanking those gentlemen who visited Combe, and gave public notice of those Grapes while they were still growing. Mr. McDonald, as might be expected from a man of his genius and enterprise, is a strong advocate for experiment by grafting; but in the case of the Barbarossa I believe he has but one opinion, and that is that it is best on its own roots.

The mania for grafting is at this moment running very high, and there is no doubt but it will produce some wonder-

ful results. In the midland counties Osborn's new White Winter Broccoli is inclined to be rather delicate, would it add, do you think, to the strength of its constitution to work it on a Brussels Sprout?—Wm. MILLER.

### LA CONSTANTE STRAWBERRY.

AFTER several recent efforts to throw a doubtful light upon this really grand Strawberry, I was particularly gratified this morning, on perusing the last Number of THE JOURNAL OF HORTICULTURE, to see that "A FRAGARIAN" (and a very clever one too), who evidently has no reason to further the interests of one party rather than another, renders full justice to the superior qualities of La Constante. Much has been said already about this splendid variety; still I may be permitted to add a few words, as I am, and shall always be, proud of having largely contributed towards its distribution in France, as well as in England and elsewhere.

Soon after I had procured the first plants from the raiser, M. de Jonghe, I sent some to my late and much-regretted friend Nicholson at Eaglescliffe; and I believe it is from thence that most parties who possess it now in Great Britain have obtained their stock. Mr. Nicholson, in one of the last kind letters he wrote me, insisted particularly upon La Constante being a kind that "ought to be in every garden." Still Mr. N. lived a good deal further north than Bedale. I have had the satisfaction of seeing with my own eyes, during several visits to England, the great success of La Constante with gentlemen who are numbered amongst the most skilful Strawberry growers; suffice it to mention W. Roden, Esq., of Kidderminster, and Henry Doubleday, Esq., of Epping, who I am sure will readily endorse what I say.

Mr. Thomas Rivers, a first-rate authority, writes in his last fruit catalogue as follows:—"No. 14, La Constante.—Large, conical, and of a deep crimson. Its peculiar aroma is remarkable. A great bearer. Much resembles seedling Eliza in its peculiar robust growth."

In America, where people generally have a great prejudice against European Strawberries, La Constante has obtained the highest honours, and at a Boston Show the highest prize, a silver cup, ever awarded to any Strawberry. It is now so popular in the United States, that they call it the best foreign Strawberry introduced.—FERDINAND GLOBE, *Les Sablons, Seine-et-Marne.*

### DUTIES OF A FOREMAN IN A GENTLEMAN'S GARDEN.

WILL you inform me what you consider the duties of a foreman in a private establishment, where the work is principally under glass? Ought he to be expected to look round the establishment every Sunday—say once—when he has what he terms permanent duty every third Sunday (about three hours)? Lodging is provided at the place.—YORKSHIRE.

[There is no rule for regulating the duties of a foreman in a private or any other establishment. These rules must in every place be a matter of arrangement between the head gardener and yourself, and it is best for all parties when these matters are stated clearly in detail. You should not, however, forget that the position of foreman gives you great advantages over the other gardeners, and especially when you are chiefly employed in the houses; and these advantages should lead you rather to increase than to lessen your responsibility. Now to your question—"Ought he to be expected to look round the establishment every Sunday—say once—when he has what he terms permanent duty every third Sunday (about three hours)?" In general we say Yes; and more especially when houses constitute your charge. No doubt if you wished to leave on a Saturday night, or very early on a Sunday morning, at times, there would be a willingness to make arrangements to meet your wishes; but without such arrangements we can easily fancy what would be the result in houses—say forcing-houses—at this season, if the person who generally superintended them were to leave them to anybody's care, just to do as he

liked, for two days out of every twenty-one days. Unity of system is one of the means of success. In such a case, whatever the time the foreman left, we should expect him to give the necessary instructions to the person in charge on Sunday, and also to see that everything was right before he went to sleep at night. The man who would decline to do this is not a proper person to be a foreman, and should not undertake the responsibility. In fickle times and fickle weather he will not confine his attention even to these two times, and, without this anxiety, there can be little progress.

There are few places where the duties of Sunday are not made as light as possible, by everything being watered that needed it on Saturday; but in most cases, where there is much glass, attention must be given to air, shading, covering, &c., not involving so much labour as attention, as a neglect of air-giving for half an hour or an hour might ruin a crop; and a whole bushel of "I'm so sorry—it can't be helped," will not fix Peaches on trees from which they have fallen. It is true that some men object to do anything on Sunday, take their stand on the fourth Commandment, decline to do what is not a work of necessity or mercy, and tell us that contributing to mere luxury is no work of necessity. Well, we find no fault with them for holding such opinions, and acting up to them, but we may question their prudence if they have anything to do with gardening in these times, when it is becoming more and more a matter of luxury. The looking after what is grown under artificial circumstances, must be considered quite as much a work of necessity and mercy as the giving of water and food to our domestic animals. There is, however, bad management in foreman and master, if work has to be done on the Sunday which could be equally well and profitably done on the Saturday or Monday.]

### THE BALANCE SHEET OF THE ROYAL HORTICULTURAL SOCIETY.

As I do not expect that many of your readers will take the trouble to wade through the accounts of the Royal Horticultural Society, I propose, with your permission, to put forward a few of the most salient points in as short a compass as possible.

First, as to the form of the accounts. As long as the balances were in favour of the Society we had an account headed in one year "Assets and Liabilities;" in another year "Profit and Loss." In 1861 this account showed a balance in favour of the Society of £10,623. Since, however, the tables have turned, and our liabilities on each year's account have been greater than our assets, this heading has been carefully struck out, otherwise this year it would have stood thus—

Assets..... £3295 | Liabilities ..... £10,939

I propose, before I finish, to show by what confiscation of property even this small amount of assets is obtained.

Secondly, as to the accounts themselves. The balance of £1433 from 1863 is equalled by the liabilities from 1863 of exactly the same sum of £1433; but there is this to be observed, that the sum of £500 for sculpture, which still remains unpaid, was in the 1863 account charged to the balance of £1433. In 1864 the admission fees were £420, in 1861 £1990.

The fêtes stood thus—

Receipts in 1864 ..... £1433 | Expenses in 1864 ..... £2174  
 " in 1861 ..... 4003 " in 1861 ..... 2897

Thus, in 1864, with a vastly increased number of members, we have a loss of £691, where in 1861 we had a gain of £1206. Among the items of expenditure we have, in 1864, an item of about £400 for a *conversazione*: as only three members of the Council were present to receive the guests, they cost the Society a little more than £100 a-head. It may be said that the loss has been caused by increased expenditure on horticulture; but, as an example, in 1864 the Society allowed their Fruit and Flower Committees £150, when in 1861 these same Committees were credited with £285. On the skittle alleys and funereal embellishments of South Kensington the Society expended the sum of £2552; but surely that is museum art, not horticulture. Pisciculture cost us £130. What did we get by it? Nothing. The Journal cost £333, and except as a vehicle for praising the

Council, what is it? The next item I beg to call your attention to is rent, rates, &c., £714. In the English of the Council rent does not mean rent, for this £714 is the amount of the rates, taxes, &c., without anything being allowed for the annual rent of £2400. I should like to analyse the other accounts, but fear to infringe on the patience of your readers.

To show how the assets balance of £2647 was arrived at, I take the life-composition account. By that a sum of £6713 stands to the credit of the life-composition fund. By the spirit of the Charter, and the 13th clause of the Agreement, this fund is sacredly set apart, under certain conditions, to meet the claims of the composition life-holders. This year, under the dictatorship of Mr. Cole, has been so terribly disastrous that, to prevent the Society seeing the whole amount of the deficit, the Council has (besides £500 of last assets), confiscated, out of this sum of £6713, no less a sum than £4066. This leaves the balance of £2647, really the remainder of the property of the composition life-holders, so sacredly guaranteed to them in its entirety by the Charter. This balance, even, does not really exist, as £2748 is now due to the Treasurer. Had this fund not been confiscated the deficit this year would have amounted to more than £15,000!

Now, shortly I propose to consider the effect of the balance sheet on the prospects of the different classes of Fellows. The annual subscribers will withdraw directly the insolvency of the Society is declared. As to the life-composition holders, their fund, guaranteed by the Society, is gone—not one farthing really remains. Practically, anybody now paying a life composition, pays it not on the guarantee of the life-composition fund and the Charter, but on that of an insolvent society—their money is spent before it is actually paid!

Lastly, as to the debenture holders. The Society has not paid a tangible amount of rent for two years. This debt, before the end of the ten years, when the gardens become forfeited to the Commissioners of 1851, will amount to about £20,000. To this sum must be added the sum of—say £3500 yearly deficiency, which, without interest, will amount to about £24,000. As the Commissioners, to whom this £20,000 will be then due, are only responsible for £20,000 of debentures, the unfortunate holders will have only Chiswick to look to for payment. What dividend will they be likely to get, after the public creditors for £24,000 have had what they can from the realisation of Chiswick?

One question more. Where is the interest on the debentures to come from next year? (see clause 14, "Agreement.") Do let us have one more struggle for honesty and the Horticultural Society. Let us try to prevent the evil day, when

"To E. T. Smith the gardens sold,  
 Shall trodden be by hoids bold;  
 And Cremorne nymphs the livelong day  
 With D— and C— at 'skittles' play."

—AN UNFORTUNATE LIFER.

### THE ROYAL HORTICULTURAL SOCIETY.

WITH the snow whitening the earth, and the roads so slippery as to render locomotion, whether to man or horse, a task of no little difficulty and some danger, there was but little prospect of there being much to be seen at the weekly show, more especially as Begonias were to be its special attraction; accordingly we were not disappointed when we found none there, save a few from the Society's own garden.

Mr. Bull, Chelsea, sent some Aracariæ, among which were Cooki, Bidwilli, and a nice little plant of Rulei; also, four plants of Libocedrus Doniana. W. Mercer, Esq., Staplehurst, had Eucharis amazonica; Lady Caroline Legge, Camellias; Mr. W. Smyth, gardener to Lord Sondes, Elmham Hall, a very good specimen Epacris, Ardisia crenulata, Scarlet Nonpareil and Boston Russet Apples, and Beurré de Rance Pears; and Major Trevor Clarke, Chrysanthemums Prince Albert and Andromeda. Mr. Melville, gardener to the Earl of Roseberry, Dalmeny Park, Edinburgh, sent his Improved Hardy Autumn or Winter Broccoli, in which, from the leaves growing over the curd, the latter is protected from the frost and sudden thawing by which this crop is so frequently cut off.

### WHITE ZINC PAINT.

I AM pleased to be able to inform your correspondent, "J. K.," No. 201, page 91, that three years ago I was recommended to use zinc white in lieu of white lead paint. I did so on some "frame work," and as I had not quite enough to complete the job, I finished with white lead. I have just examined each, side by side, and did I now use white paint, I should for the future continue to use white zinc; it is hard and smooth though dry-looking, whereas (as I have many times observed), all the oil appears dried out of the white lead, leaving a dry coat of lime-like substance that with little trouble will rub or wash off. This led me to ask the cause of a friend, an experienced house painter, and ask for a remedy. He replied, "Use (if it must be white), zinc white; but the most durable, and I think the best, colours of all other paints for out-door buildings, are stone colours."

I fully agree with him, having by chance, thinking the colour would best harmonise with its surroundings, had a little greenhouse painted with a tolerably light stone colour four years ago, and it is, though equally exposed, in a much better state of preservation than that where zinc white was used three years since, the shiny appearance given by the oil remaining to a much greater extent than in any other paint I have ever noticed out of doors; therefore, I recommend stone-coloured paints only, and biennial painting. One good coat of paint carefully laid on will then in most instances be sufficient to keep horticultural buildings in first-rate condition and appearance; and then, that "J. K." would find the annoyance of putty more imaginary than real, is the conviction of—R. H. POYNTER, *Taunton*.

### AZALEA SHOOTS AND LEAVES TURNED BROWN.

WILL you please give me your opinion of the enclosed pieces of Azaleas? My employer imported a large collection about fourteen months ago. They all did well last season, made good wood, and set well with bloom-buds. I anticipated a good show next spring, but my hopes are blighted. Soon after they were put into their winter quarters a few of them began to turn brown at the points of the leaves, and in time the whole leaf was brown. The brownness then got into the bud, and next into the branch, until the whole head of the plant was gone. I am puzzled to find the head dead, and the roots and stock in good health. If they began to go at the roots first I might then think it was some mismanagement; but I do not think it is that, as it is a general cry about here that most gardeners have their Azaleas more or less gone, or going. A friend of mine has lost a dozen specimen plants, worth £2 each, in the same way as that in which mine are going.—J. M., *Edgbaston*.

[We cannot make out the cause of this decay. We thought we noticed a trace of thrips, but could not be quite sure. Of course they have not been frosted? A similar case was brought under our notice last season; but in that case there was strong suspicion that they had been maliciously syringed with a saline or acid solution. We advised, however, the matter to be allowed to rest, as it would have been difficult to establish the point. We hope you have no suspicions pointing that way.]

### GARDENERS' DWELLINGS AND CLOTHING.

YOUR worthy contributor Mr. Fish, I was glad to observe, has given prominence to the two very important matters of gardeners' dwellings and the clothing of men who are employed in forcing-houses, and consequently exposed to violent and sudden variations of temperature.

All who have a spark of humanity about them must admit that these are subjects of great importance, involving as they do the health and comfort, aye, and morality too, of a class who administer so largely to the most rational enjoyment and pleasure of their employers, and whose life, before they are capable of filling a head gardener's situation, is one attended with a very considerable amount of privation. It must, therefore, surely be admitted that these are subjects well worthy of being brought under consideration in the pages of such a periodical as THE JOURNAL OF HORTICULTURE.

The improvement of the dwellings of agricultural labourers has for some time been prominently agitated in agricultural literature with good results; and why should not the improvement of gardeners' dwellings be similarly dealt with in the gardening press? It certainly cannot be said that there is no necessity for improvement in the houses which are inhabited by both head and under gardeners. True, as Mr. Fish observes, there is improvement going on, and some few gardeners, such as Mr. Robson, occupy houses which may be considered models for even first-class establishments, being roomy, healthily situated, worthy of the intelligence and persevering energy of those by whom they are inhabited, and creditable to the employers and their estates. But this is by no means the rule, for it is well known that too many, both head and under gardeners, still occupy an apartment in which my lord and the squire would not trust their hunters or retrievers for a month, and in which, in fact, these animals would not exist in health. Too often are gardeners to be found huddled up into these north lean-to's, referred to by Mr. Fish, into the windows and doors of which the health and life-giving rays of the sun can never enter. Most especially is this applicable to the young gardeners of the establishment; they are huddled into some out-of-sight corner with a north aspect, and in numbers of cases have only one apartment in which to cook, live, and sleep, without the comfort-giving hand of a woman either to cook or clean for them. How, then, can it be otherwise than, as Mr. Fish instances, that the seeds of disease are sown and fostered in such places of abode? There they are under the necessity, after a hard day's toil, of inhaling over and over again the damp stagnant air of a small apartment with a chilly north aspect, which is rendered more poisonous still by being turned into the abode of a human being. Ventilation and aspect, which are so duly and carefully studied and provided for in the case of plants, are entirely overlooked in the housing of the human machines that are required to possess the intelligence and unwearied application which are necessary for the cultivation of plants.

This picture is a dark one, but not one shade beyond the truth. I could cite numberless instances as proofs of this. Doubtless great improvement could be brought about by head gardeners, both in their own and in the dwellings of those under them, were they to earnestly bring the matter under the consideration of their employers. I have no idea of heaping all the blame and responsibility on the employer. Surely there are, it is to be hoped, not many among the nobility and gentry who are so callous to the well-being and comfort of servants who suit them as not to take some steps towards at least mitigating the evils under consideration; and I know for a fact that many gardeners continue, and make up their mind to experience, all the ills entailed upon them and their offspring by small and unhealthy apartments, merely because they do not like to incur obligations or expense on their account. I submit that there is no obligation in the matter, and that a gardener who suits his employer has at least a moral right to be housed in such a manner that the lives of himself and family may not be placed in jeopardy. Such delicacy is a false delicacy, and the moral sense of that employer must be low indeed who will not listen to the representations of his servants in such a case, and take steps accordingly.

Speaking of gardeners' families I cannot refrain from referring to those who advertise their little ones as incumbances. What a libel upon the best feelings of our nature! Surely the term has been originally coined in the shrivelled heart of some old bachelor.

I agree fully with Mr. Fish as to the rash folly of young men employed in the hothouses needlessly exposing themselves suddenly, with their coats off and sleeves tucked up, to chilling winds, while they are perspiring at every pore. The strong may, and often do, brave such cruel and foolish treatment of themselves for years, but if they like to have grey locks they will wish they had acted otherwise, or the experience of their fathers is not worth much. The infraction of the laws of health in so violent a manner will sooner or later be followed by punishment and suffering, as surely as shadow follows substance.

I know of few employments which warrant more care in clothing than that of a young man who has the care of hothouses by night and by day, and in saying this I speak from

some experience. Such an employment requires warm clothing to prevent the sudden reactions which will otherwise take place in the system. Let me advise all young gardeners, and old ones too, to wear next their skin a flannel, and over that and under their shirt a chamois-skin waistcoat, double-breasted up to their throat, and reaching down to their loins. The writer never wore anything from which he derived so much comfort, and I may say safety against cold. It is light and pliable, and when coming out of a high temperature, with the blood at the surface, the wind cannot pierce the chamois and send the blood suddenly to the vitals to breed catarrh and other inflammations. I have to go frequently from hothouses into the teeth of a bitter east wind off the sea, and it is astonishing how little its effects are felt with such an article of clothing.

Mr. Fish refers to the good practice of old gardeners in preventing the cold frosty air from coming suddenly in contact with their young Cucumbers, and to their practice of "sifting" the wind through a mat, or something else; and on the same principle he might have wisely recommended gardeners to wear their moustache, which wise provision of nature, if good for the protection of the lungs of any class of men against cold air and dust, must be especially so in the case of young gardeners who have to attend to fires and work in hothouses loaded with moisture. I do not know whether Mr. Fish be patriarchal enough to recommend the moustache for the protection of the human lungs, but certain I am that he will not treat plants so cruelly as to deprive them of any appendage with which their Maker has furnished them for their protection.

By many a strong young fellow these precautions may be smiled at; but I would add my warning voice to that of Mr. Fish, that the strongest, if they live, will ultimately wish they had paid more attention to the laws of health.—ONE WHO IS COMFORTABLY HOUSED.

RAISING GOOSEBERRIES FROM SEED.

In the Journal of the 31st of January attention is called to raising new kinds of Gooseberries from seed. I give the results of an effort in that direction, which as regards success in number is poor encouragement, but for quality satisfactory.

It is five or six years since I selected ninety of what appeared the best seedlings, judging by the leaf, and although I have none but what I consider good, either as to size or quality, in my garden, and no other garden near it, there were twenty of the most worthless imaginable, and only two out of the ninety were worth saving.

Although not large, they are such distinct new varieties, and of such superior quality, as to be well worthy of cultivation. No. 1 is a dull red, very early, very fine skin, full of juice, and very sweet, and to my taste superior to the Red Champagne. No. 2 is not a dessert fruit, but the most splendid in appearance for bright colour I ever saw; its syrup is the same colour, and makes a beautiful preserve both in colour and flavour. A nobleman's gardener, who has seen it, considers it the handsomest Gooseberry he ever saw; it is in appearance most like the Ashton Red, but nearly double its size, although not to be considered large compared with prize kinds.

It is desirable to raise improved varieties of fruit if possible; but if my trouble, time, and experience are any rule, there is not great inducement to make the attempt.—J. CARLEIDGE, Kirton-in-Lindsey.

THE CLIMBING DEVONIENSIS ROSE.

I HAVE received a very kind letter from Mr. Henry Curtis, of the Devon Rosery, Torquay, and also two splendid Briar specimens of the above Rose. He is kind enough to acknowledge the benefit that he has received from my articles of one kind or another. One of the specimens is on a dwarf Briar, and the other on a standard. The growth of both is quite wonderful. The Rose bids to be a great acquisition; the wood is not only luxuriant but of a hardy nature.

As letters addressed to me continually go to the Rushtons, in Yorkshire, I shall be obliged to all correspondents, if they will add the word Tarrant before Rushton.—W. F. RADCLIFFE, Tarrant Rushton, Blandford, Dorset.

The highest barometer during the year was 30.840 on Nov. 6, at 9 A.M. Calm. The lowest ditto..... 28.718 on Nov. 14, at 9 A.M. N.N.W. The greatest heat of the ground at 1 foot deep was 65°.50 on Aug. 16 and 17. The prevailing wind, S.W., 64 days. The least ditto..... 28.718 on Nov. 14, at 9 A.M. N.N.W. The lowest temperature of the air was 16° on Feb. 25. N.E. The greatest rainfall in 24 hours was 1.10 on April 5; wind calm. Note.—I have reason to think that my barometer reads 1-10th of an inch too high.—T. WARNE.

METEOROLOGICAL OBSERVATIONS FOR 1864, WARRINGSTOWN, CO. DOWN, IRELAND. Latitude 54° 25' 52" North. Longitude 6° 17' 56" West. Height above sea level, 190 feet.

## THE ARBORETUM—DECIDUOUS TREES.

(Continued from page 90.)

## ACER (THE MAPLE).

The genus *Acer* includes a great variety of species, a few of which are evergreen, but these are chiefly tropical or subtropical. All, or nearly all, the deciduous kinds are perfectly hardy, and most of them extremely valuable for their timber. Some are low, others medium-sized trees; but *Aceriocarpon*, *A. macrophyllum*, and other large-leaved kinds form timber trees of considerable magnitude. Their foliage is as varied as their size, and gives them their ornamental character. The Maples, therefore, should be a conspicuous feature in the arboretum. The flowers are green and inconspicuous; the fruit is double, each division containing one single-seeded cavity, and extended at the back into a kind of wing, called a key in English, or *samara* by botanists.

*ACER TATARICUM* (the Tartarian Maple), has heart-shaped leaves, oblong, unequal-ly serrated, and usually undivided; hence, a very distinct variety. A native of southern Asiatic Russia, Tartary, &c.

*A. SPICATUM* (the Spiked Maple).—A low tree found in the United States and Canada. Loudon says, "That it is very ornamental in autumn, from its small keys which are fixed upon slender pendulous spikes, and have their membranous wings beautifully tinged with red when ripe."

*A. OPULUS* (the Guelder-Rose Maple).—A small tree growing plentifully on the Pyrenees and French Alps. "It is considered preferable to all the other Ma-

ples for its wood, which is hard and compact, not easily split, and so homogeneous in its texture that it is almost impossible to distinguish it in its annual layers."

*A. OBTUSATUM* (the Neapolitan Maple).—Leaves heart-shaped, roundish, five-lobed, woolly beneath. Found in Hungary, Croatia, and many parts of Italy. It frequently reaches the height of 45 feet, and is extremely striking with its reddish purple branches. Of this beautiful tree we read—"It is certainly very singular that so fine a tree as this, occupying so large a tract of country, frequently visited by English tourists, should be almost unknown in this country; and yet, although it is perfectly hardy and very easily multiplied, it is scarcely ever met with in any but botanical collections." Here, then, is a case calling for attention. Loudon says there is a specimen in the arboretum at Chiswick.

If so, the Royal Horticultural Society would do well to propagate and distribute it. I am inclined to believe that the *Acer* reported by Mr. Gordon, in the Number for September 6, 1864, is, in reality, *A. obtusum*, his description corresponding with it, and the distinctive character between it and *A. platanoides* correctly pointed out. Although Loudon has given *A. Lobelii* as a variety of *A. platanoides*, he evidently had some doubts about it, as may be seen by referring to his "Arboretum," vol. i., p. 431. I feel no hesitation in stating my belief, that when trees are more generally studied, and their character better understood, it will be found that many that now go by a distinct name will be found to be the same as some other variety. Of *Acer obtusum* there is no doubt; of *A. Lobelii* there appears to be much. So *A. opalis* (Italy), and *A. opulus* (France), formerly described as two different kinds, are undoubtedly but one.

*A. MONSPESULANUM* (the Montpellier Maple), has leaves slightly cordate, with three entire, nearly equal, diverging lobes. Found in the south of France, and in Spain, in rocky situations. In its native countries it sometimes attains a height of 40 feet; but in England the tree is much less, and "may be considered as purely one of ornament, and as such, it well deserves a place in every collection."

*A. PLATANOIDES* (the Norway Maple).—One of the finest and best known of the exotic Ma-

*Acer circinatum.*

ples, with very handsome, glossy, deep green leaves, not unlike the common Sycamore. A striped variety of this species, called by gardeners the Silver-striped Maple, is sometimes met with in kept grounds. Loudon describes another variety of it, called *A. platanoides laciniatum*, as very distinct, with leaves deeply and variously cut. *A. platanoides purpureum* can hardly be reckoned as another variety.

*A. MACROPHYLLUM* (the Broad-leaved Maple).—Leaves divided into five deep, spreading, slightly lobed segments, the middle one of which is often narrow at the base, and the lower ones generally smaller than the others. The finest of the North American varieties. It also produces useful timber.

*A. VILLOSUM* (the Downy Maple).—Described as a large tree, found in the Himalaya mountains, approaching the limits of perpetual snow. There are very few specimens

in England, and it is one of the kinds but yet very little known.

Acer Monspeulanum.

**A. STRIATUM** (the Striped-barked Maple).—An American variety, growing from 10 to 15 feet high, forming a considerable part of the underwood among Beeches, Hemlock Spruce, &c. Its wood, which is very white, is useful for inlaying. When cultivated it grows much larger than in its native wilds. "The trunk and branches are covered with a smooth green bark, longitudinally marked with black and white stripes, by which the tree is readily distinguished at all seasons of the year." It is likewise remarkable for the bright rosy tint of its young leaves in spring.

**A. SACCHARINUM** (the Sugar Maple).—Leaves five-lobed, taper-pointed, and very coarsely toothed. A native of British North American provinces, where it is found in immense quantities, giving in autumn to the woods of those countries a fine crimson hue, caused by the changing of the leaves. It is called the Sugar Maple, from the saccharine matter contained in the ascending sap, from which brown sugar is obtained. It is said that the Sugar Maple does not thrive well in England, and that even when in health it does not attain a greater height than 15 feet, whereas in its native home it has been found to reach 80 feet. This may arise from the comparative mildness of our winters, or its being subjected to much smaller extremes of temperature at opposite seasons. It would be satisfactory to know if there are specimens which have exceeded 15 feet in this country.

**A. ERIOCARPON** (commonly known in America as the White Maple).—It is a very rapid grower, and its wood is of little value except for charcoal for gunpowder. "It is often

confounded with *A. rubrum*, which in the leaves it nearly resembles, but it differs in its fruit and flowers."

**A. RUBRUM** (the Red Maple).—It derives its name from the deep red colour of the flowers in spring, and the leaves and seed-vessels in autumn. The leaves are heart-shaped at the base, glaucous beneath, deeply and unequally toothed, very much like *A. eriocarpon*, but the leaves are altogether smaller than that variety. Its wood is also harder and of a finer and closer grain; hence, like the other harder kinds of Maple, it is easily wrought in the lathe, and acquires by polishing a glossy and silken surface. It is one of the most ornamental of the Maples, but thrives best in damp situations. Found in Canada, and abundantly in different parts of the United States.

**A. CIRCINATUM** (the Curled Maple from North-western America).—Its leaves are seven-lobed, the lower two smaller than the others, acutely notched. Loudon says, "The wood is fine, white, close grained, very tough, and susceptible of a good polish." We are told that it is a small and almost worthless tree. The light tint of its foliage, and the regular form of its leaves, give it a distinctive character, and a right to a place in the arboretum.

**A. CAUDATUM** is remarkable for the long-pointed middle lobe of its leaves, whence its name. It is found in the higher regions of Himalaya Mountains, in Nepaul. It is as yet but little known in this country.

**A. BARBATUM**.—An American variety, and it must be considered a shrub rather than a tree. It has been propagated and distributed under the name of *A. trilobatum*, but it is seldom met with.

**A. PALMATUM** is described as a Japanese kind, introduced in 1832. It is also said to be a very striking variety, which, judging from whence it came, would most likely be the case. Loudon thought it rather tender; but now that we know more about Japanese plants, there is not much fear that it would not flourish in our climate.

mate. Can any one kindly furnish information on this or any other Japanese variety?

**A. CAMPESTRE** is the common Maple of our shaws and hedgerows.—ADOLPHUS H. KENT.

(To be continued.)

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

It is now necessary to determine what the different quarters of the garden shall be cropped with during the season. The chief rule to be observed with all annual vegetables is never to have two crops of the same class directly following each other. Though excellent plans of rotation may be laid

Acer eriocarpon.

down, yet the period that will elapse before the ground is again occupied by a similar crop will depend upon the wants of the establishment and the quantity of ground at the disposal of the gardener. Those who require to have several crops on the ground at the same time will find that Celery is a good preparation for Carrots, Turnips, Parsnips, Onions, and early Cauliflowers, or for Peas, with Potatoes and Winter Greens, or Broccoli, between the rows. Autumn-sown Onions may be succeeded by Spinach, Lettuce, &c.; and early Cauliflowers by autumn Onions. Spring-sown Onions will be advantageously succeeded by Cabbages in beds, with Scarlet Runners between; and if the Cabbages stand all summer and next winter the ground will come in in the spring, along with Broccoli ground, for Celery, Potatoes, and Peas, the early Potatoes being planted in the trenches, and the Peas sown on the ridges. *Asparagus*, give plenty of air to this and all other crops in frames, and make fresh beds. *Carrots*, sow in frames, and thin those already up. Sow seed for succession crops. *Cauliflowers*, plant out from the seed-pans all the young plants before they become too much crowded, and if needful make fresh sowings. *Cucumbers*, the fruiting-bed should now be made, if the seeds are sown; and as soon as the heat is up the lights should be raised to allow the steam to escape. After this has taken place, twice or three times a-week fork up the dung to the depth of a foot or more until the plants are nearly ready to turn out. As soon as the seeds are up, and the two seed-leaves fully developed, pot in leaf mould in 48-sized pots; let the roots touch the bottom, and only partly fill the pot with soil, adding more at intervals of a day or two. *Lettuce*, sow a crop of Cos in frames and in the open ground. *Potatoes*, plant some early sort in a sheltered situation if not already done. *Spinach*, a small quantity of this may now be sown with advantage.

#### FRUIT GARDEN.

If any root-pruning of fruit trees has yet to be done let this be attended to without further loss of time, and see that trees exposed to wind are securely staked. Prune Raspberries. Any Gooseberries or Currants not previously pruned should forthwith be attended to. Make arrangements to procure a sufficient supply of pea-sticks, and collect fir boughs to protect the blossom of Peach and Apricot trees.

#### FLOWER GARDEN.

See that all planting is completed forthwith. Improve as much as possible all outlines. Plant fresh masses or groups where necessary, and introduce specimen plants where fitting opportunities offer. It is bad taste to plant single specimens in recesses. They should be used as a general rule to give deep shadows, and to throw the prominent features into bold relief. Give lawns a good rolling after wet. Proceed with edging the walks; keep these clean, and roll frequently to make them firm for walking upon, and also to prevent the growth of weeds. Where it may be necessary to increase the stock of any of the varieties of Dahlias these should be placed in heat at once in order to secure cuttings. Look to Crocus bulbs, &c., planted in beds, and protect them from the depredations of mice. Auriculas may now be permitted to grow, and must be well secured from frosts and cold rains. Heartsease may have the earth stirred between them as soon as the weather will permit, and some well-decomposed cowdung between the plants will greatly increase their size.

#### GREENHOUSE AND CONSERVATORY.

Shift and tie out Pelargoniums as may be required, and allow them plenty of space after this time, with all the light possible, and a free circulation of air whenever the weather will permit, but avoid cold north-easterly winds, which are very injurious to plants in active growth. Do not allow herbaceous Calceolarias to suffer for want of pot-room, as a check at the present season might throw them prematurely into flower. Cinerarias will now require frequent shifting and placing at great distances from each other, in order that the air may be permitted to circulate freely amongst them. Lose no time in improving the drainage of any specimens that require such attention, and endeavour to secure a healthy vigorous root-action, which is of great importance, especially in the case of hardwooded plants. In greenhouses damp and mildew are the great enemies to be guarded against, and these must be sharply looked after, especially in the case of plants that have not ripened their growth.

If the former is troublesome it must be got rid of by means of free ventilation on mild days, using a little fire heat at the same time; and for the latter a dry airy atmosphere is the best preventive, but the plants should be frequently examined, applying sulphur on the first appearance of the enemy. Very little water will be required here at present, but the plants should be carefully looked over about twice a-week, so as to make sure that nothing is allowed to feel the want of it. For mixed greenhouses it is somewhat difficult to give precise directions. Plants of all climes occasionally obtain a place here, and no special treatment in regard to temperature can long be indulged in with impunity. As a principle, therefore, of frequent and somewhat harmless application, we would advise a rather free increase of heat on sunny days early in the afternoon for a few hours, sinking at night to the old point, or nearly so. In this structure there will frequently be found Ericas, Pelargoniums, New Holland plants, bulbs, and even Orchids. A division of these families should therefore be made. Let the Orchids, bulbs, and plants of warm climates occupy the warmest end with little air, and the Ericas, &c., the other, with a freer circulation, the Pelargoniums may stand midway.

#### PITS AND FRAMES.

If your dung is properly prepared and quite sweet, for propagating Verbenas, Fuchsias, Petunias, &c., get a bed made up as quickly as possible below the surface of the ground, where it will retain its heat much longer than on the surface.—W. KEANE.

## DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

HERE we have done little out of doors, as until the frost of Thursday morning the ground was too wet to do anything but trenching, and even that would be better delayed until the ground is drier. Turned over some ridged-up ground intended for Carrots, Potatoes, &c., in order that it may be the better sweetened by a fresh exposure to the frost.

*Potatoes*.—Planted some frames, each set having been previously well rooted in small pots. These we planted (Ash-leaved) 15 inches from row to row, and about 7 inches in the row. We have planted thinner and thicker, but we think the above is about the best for getting the most produce in little room, and especially if the sets have been started in small single pots, as they do not grow quite so vigorously afterwards as those planted out in a bed at once. Planted out also a lot in an earth pit, covered with old sashes, a little farther apart from row to row, and they also had a slight bed of warm leaves below them. They will succeed those in frames, as the latter will do those in large pots, to some of which we gave an earthing up, chiefly of loam and leaf mould, to prevent the tubers near the top being greened. These have grown so very strong that we have been obliged to move the pots to give them more room, so that the light and air may play around them, as if the pots stand so thick that the heads look like a thicket they do not tuber so quickly, or ripen so well, so as to become mealy, without which, in our opinion, a new Potato is little better than a Jerusalem Artichoke. When these and our early Potatoes are apt to grow too long in the stalk, or stem, we do not check them by cutting off the top, but we nip out the terminal buds, which keeps them dwarfer and, we believe, does no harm. It is owing to the little head they make that among all the fine new kinds, we prefer the Ash-leaf, the Early Frame, Early May, &c., for all early work. Out of doors they may be sooner cleared off the ground, or the next crop may be planted between them with less risk of injury to either. As respects autumn planting we consider it to be applicable chiefly to light dry soils. In heavy rich land the sets are apt to be much injured in winter, and the produce comes no sooner than from careful spring planting. Those above, planted in frames and the earth pit, were left in the ridge form, so that a little more earth might be added afterwards in a nice sunny warm day, the soil used being partly fresh and partly what had been used for Melons and Cucumbers, but all in a nice friable condition, and dry rather than wet. For placing over such a mild hotbed the soil should be drier than for ordinary planting, as moisture will

ascend from the damp leaves. One reason for having the Potatoes at once in the ridge form was that the hollow between might be appropriated to

**Peas Sown on Turves.**—These were cut 4 inches wide, from 2 to 3 inches deep, and 15 inches long, and had a groove 1 inch deep cut along the centre, in which the Peas were sown, and covered with light soil and leaf mould. The kinds used were chiefly Sangster's No. 1; Sebastopol, a kind sent to us last year, and which promised to be early; Tom Thumb, Bishop's Dwarf, &c. These would be transplanted in pieces to rows in the open air, when the roots were peering all through the turf, and the soil outside was nice, warm, and mellow; and after many years' trial, we find this plan gives us rather earlier Peas, and with much less trouble than having to look after slugs, rats, and mice all the winter. Broad or garden Beans were sown in the same manner, only the groove in the middle of the turf was made deeper. Some were the Dwarf Fan, the Mazagan, and the Early Long-pod. The last is a very sweet prolific Bean, and in our opinion much more profitable than some of the crack Wonderfuls, which do not produce in proportion to the length and size of the pods. When it becomes fashionable to dress the young pods like young fresh Kidney Beans, then, of course, the size of the pod might be an object.

Gave more room to the Tom Thumb Peas in 8 and 12-inch pots in a frame, as we cannot as yet give them a better place. They would be more forward if they had a little dry heat. Everything seemed to prick up the foliage to the sun of Thursday, as we have scarcely seen his rays for three weeks, and much growth in such circumstances was rather to be avoided than encouraged.

**Carrots.**—Made up a slight hotbed chiefly from tree leaves for a two-light box, and after covering with fresh light soil for 7 inches, sowed with Early Horn and Radishes. We often sow broadcast, but this time we drew slight drills  $4\frac{1}{2}$  inches apart, and sowed one row with Carrots, and the other with Radishes, of the Early Frame kinds. This will enable us to draw the Radishes without disturbing the ground about the young Carrots. If these Carrots are left rather thick and the most forward regularly pulled, we know of nothing so economical for produce as such a bed. The Dutch Forcing Carrot will give a great number of little dots, half the size of the Horn Carrot. Seedsmen should be careful of the quality of the latter, so as to save only from high-coloured specimens, as though lighter-coloured ones may be equally sweet, they will not please the cook. The same remark applies to Beet. It cannot be too dark. Even if equally rich in saccharine matter it will not please; but the darker in colour the richer it will generally be. The size is of less importance; in fact, many prefer roots from 1 to 2 inches in diameter to those which are larger.

#### FRUIT GARDEN.

Out of doors pruned a little on such days as Thursday. On a wet day pruned the trees, Peaches and Nectarines, on the back wall of an orchard-house. The trees are tied to cast metal nails fixed in the wall as studs at regular distances, which prevents the necessity of filling either a new or old wall with nail holes, one of the best refuges for insects and their eggs and larvæ. The old pieces of list, and clippings from the clothiers, are just as nice nests for eggs, &c., as the best breeders among insects could wish. We will wash all these trees, and also the wall, slightly with soap water, as soon as we have another suitable day, before painting them over with clay, sulphur, or a little Gishurst. In the meantime we have syringed all the wood and the wall with soap water at about 160° in temperature.

**Strawberries.**—No weather could have been worse for early ones swelling or in bloom, but a few days like Thursday will make them all right. We have moved all the most forward where they could have most sunlight and air, and took in a lot more from frames, where they had just been started slowly and gradually. Frames or pits with just a little bottom heat below them are very good for this purpose; but unless with those having considerable practice it is dangerous to plunge the pots into anything like a hotbed. A place with a little dry heat, which you could make moist at will, would be better than any place of a hotbed character. When the latter is used the little heat from it will bring on the plants gradually, but it will be safer to set the pots on the surface, or merely fix them in the bed an inch or two in

depth. We have known of hundreds of fine plants that did little or no good just from plunging the pots, and thus allowing them to get too hot at the roots. Last year we prophesied great results from a set of plants, but the owner did but little with them, and sent us a sample of the pots to look at them. When we turned the plants out in October, 1863, the ball of roots was as firm as a Dutch cheese—fine bold roots, through as well as round the outside of the balls, so thickly that you could scarcely have inserted a needle point between them. When we turned out the pots sent in February there was nothing but brown decayed roots round the ball—not a vigorous spongione to be seen. Further disclosures made all apparent—the hotbed had overdone the roots, and the top suffered in consequence. Where there is the least chance of extra heat from beneath the pots should not only stand on the surface, but it would be better if they stood not on the bed at all, but on slips or shelves of wood. Even if no danger accrues to the bud from plunging, any great stimulus by heat at first is apt to encourage foliage and leave flower-buds lagging behind.

When a vinery or Peach-house is to be started, it is just as well to set the Strawberries in their place at first, and thus they come on gradually without any danger of the roots being injured. We have always gathered earlier, however, in a Peach-house, when the plants had been encouraged a little under glass previously, and for all succession crops it is better to have the plants used to heat before they are taken into the forcing-house; but in all such cases whatever bottom heat reaches them should be very moderate indeed.

Owing to the heat and dryness of last season, our plants are in smaller pots than usual, except where two or three are in a large pot. The bulk of our early plants are in four and five-inch pots. Of these we may give more room to a few of the latest used, but we will not repeat any to be used for a month to come, if at all, as a good produce may be had from small pots with rich nourishment. As soon as we can we will give a lot of plants, runners of last season, more room in a border, with leaf mould and rough loam placed firmly round them, and after March we can lift these with large balls, and either pot or plant under glass at once. Such fresh-potted plants would be of little use now. Those thus taken up later do very well even in pots, especially if the pots are plunged in a mild hotbed, and plenty of air given to the tops to keep them cool. Here a little heat at bottom would bring the roots into activity and cause them to press against the sides of the pot, which is a different thing from roasting and parboiling roots that were as thick as they could be clustered there the previous autumn.

In a fine day the blossoms should be shaken, and a fine brush or a feather drawn over them to scatter the pollen. In a fine sunny day a slight dewing from the syringe, not a drenching, will also help the same process, just as it is helped out of doors by a warm, sunny, slight shower. An excess of damp would be apt to wash off the pollen. A dewy drizzle attended with heat and sunshine seems to open and disperse the contents of the pollen-cases. In December and January it is not uncommon to find flowers with but very little pollen, or imperfect anthers, but if the female organs are all right the dusting of the pollen from other flowers will make up the deficiency.

Sprinkled from the syringe Vines and Peaches, and Figs moving. Where there is a moist atmosphere this is of less consequence; but if these fruit trees have been painted over with Gishurst or other paints, as sulphur and clay, it is as well to soften it a little by the syringe before the buds open.

We forgot to say, as respects the orchard-house, that we watered the ground for a width of some 3 feet from the wall, as when pruning we found a few buds came off as we run our hand along them when cutting, which we attributed to overdryness. Now, were we to soak all the space at once, the evil might be increased by a too great stimulus at once. We forgot, also, to say, that after syringing the back wall and the trees on it, we would have let the frost, 5° or 6° at least, into the house, but we could not do so at present, as our fruit trees in pots are crowded together as closely as possible, and the rest of the floor is covered with Geraniums and bedding plants, which we have kept by shaking a little rough dry hay over them in frosty nights, and by putting a small fire in an iron stove when the frost was very severe. We shall be glad when we can get all these things out, in order

that we may keep back the blooming of the trees as much as possible. This is one of the secrets of success in unheated houses. When the fruit is nicely set, it is easy to hasten maturity by shutting up early with sun heat. To all with unheated fruit-houses who have not had much practice, we would, as one of the secrets of success, say, Use every means except shading to keep your buds from opening prematurely. Of course, when, as in our case, such a house must serve many purposes, it must be treated accordingly; but in an orchard-house with nothing but fruit trees, we would prevent the frost entering the soil to any depth, and if there were trees in pots or tubs, we would protect them, but now, unless in storms and very severe frosts, we would keep the houses open night and day until the buds began to open, when we would shut up on all nights except very mild ones.

ORNAMENTAL DEPARTMENT.

Went on potting Lycopods, stove and greenhouse plants, and would give bedding plants more room if we knew where to put them. Other matters much the same as last and previous weeks, which see. The only work out of doors has been turning in the rough rotten leaf mould which had been scattered on the ridged-up flower-beds and borders, and preparing some turf earth-pits for the work to which they will be soon applied. In turning over the ridges of the beds the dung will be prevented blowing about, whilst it will be kept near the surface, so as to be well aired and sweetened, as well as the earth, by exposure. The earth-beds had been helped with a little turf between the layers of earth in the walls, and turf all along the top. In the course of years the walls had crumbled inwards considerably, leaving the top turf hanging over them, so that, by walking on the top, there was a danger of bringing the wall down. Turf was too scarce to make up the deficiency, so earth was firmly beaten into the hollows, so as to come in a straight line with the overhanging turf; and, as these pits had been injured by the falling of large trees, all defects on the top of the walls were made good by fresh turf. We have not half finished yet. We mention this, however, chiefly for the benefit of our friend "WYESIDE," p. 111. In beating this inside wall of earth the man left it firm, smooth, and shining from his spade, thinking, no doubt, and quite correctly, that he had done the job, as far as he went, very nicely, and in a workmanlike manner. In summer we would have let well alone, for a number of cracks would be of little consequence; but as we may expect some frosts yet, and we did not wish the wall to be thrown down, we asked the man who did it to make his smooth surface all rough by pulling the teeth of a rake over it gently. The Editors supply the reasons. We could say a good deal of the blanket theory. We would advise the following experiment:—Encase a bottle firmly in a dry rough woollen jacket, and another, also dry, in a similar coloured cloth of smooth calico or linen, and expose both to the sun, or any other heating medium, and he will find the contents in the smooth-covered bottle will become the hottest. We are sure the reverse will just take place if both materials outside the bottle are equally kept wet, and exposed to heat. We place a bottle of water or wine in a tight-fitting woollen stocking, keep it wet, and expose it to the sun, when we wish to cool the liquor inside, not because the woollen stocking will evaporate faster than a cotton one, or one made of hard linen, but because the woollen absorbs and retains the liquid we apply much better than the other material. The subject is one of considerable importance, and we shall be glad to hear "WYESIDE'S" conclusions.—R. F.

TRADE CATALOGUES RECEIVED.

Henry Brown, 4, Commutation Row, Liverpool.—Priced Descriptive Catalogue of Garden and Agricultural Seeds, Plants, Shrubs, Trees, &c.

Hooper & Co., Central Avenue, Covent Garden Market, London.—General Spring Catalogue of Flower, Shrub, and Kitchen Garden Seeds.

COVENT GARDEN MARKET.—FEBRUARY 11.

Notwithstanding the severe weather the market continues to be well supplied. Pines are still somewhat scarce, but bothhouse Grapes are suffi-

cient for the demand, and, as remarked last week, some new ones may now be had. Greens of all kinds are plentiful, and Salads arrive daily from the continent. Green Peas from Lisbon, and a few Tomatoes, have made their appearance. Of Shaddocks, a large parcel has arrived from the West Indies. Some new Potatoes from Malta and Bermudas are to be had at 4d. per pound. In the Potato market there is still a heavy stock, and prices are unaltered.

TO CORRESPONDENTS.

FAILURE OF PEAS (*Pisum sativum*).—Grow them as advised by one of our correspondents last week. In a light soil like yours we grew large crops of Peas by mulching over the roots, and watering with diluted house sewage twice a week, and oftener in dry weather.

WORMS IN CAMELLIA POTS (*Camellia*).—The worms will do little harm so far as directly affecting the roots of the plants is concerned. The chief injury they do arises from making the soil loose about the roots and choking up the drainage, making the soil like a morass. This is the reason the soil in your pots dries so slowly, and when it does it will most likely get as hard as a brick; and when wet it will be as sour as soil taken from a stagnant ditch. Your pots, we presume, are just in the best position for being affected by the lime water, as the bad drainage will keep the water longer in the pot. A shovelful or half a peck of quicklime, and well stirred, will be sufficient for a thirty-six-gallon barrel. You may use more, but the water will be little or no stronger in consequence. Let it stand a day or so till the water is quite clear. If the lime is fresh burned the water will taste sharp if you put a little on your tongue. A good soaking or two will bring most of the worms to the top of the pot, where the poor things will wriggle and die. This plan persevered in will settle the worms, but it will not make the plants healthy, as you would wish to see them, without fresh arranging the drainage, and picking out at least some of the worst soil—the sour and claggy portions of it. In this dull weather we would, unless in extreme cases, be satisfied with doing that, instead of using frequent doses of lime water. When the ball is turned out you could catch many of the worms; and if you sent a small pointed wire through and through the ball the worms would be sure to show themselves, and as this work must be done at any rate we would prefer doing it now, instead of using two or three doses of lime water. In getting rid of the worms and a lot of the sour soil, you may require to place the plants in smaller pots, and use rather light sandy soil, to cause the fresh roots to form freely, and when they are running strongly in the fresh and well-drained soil then you may give a larger shift. The mere killing of the worms with lime water will not make your plants healthy.

MANURE FOR ROSES—ECONOMICAL FORCING-HOUSE (South Devon).—Good hotbed manure well rotted, or a mixture of horse and cow-dung one year old. Of artificials—superphosphate, and drainings from the dunghill, as the buds thrive. A hipped or span-roofed house will be the best for the purpose, either so narrow as to have a platform on each side and a walk up the middle, or so wide as to have a platform or stage in the middle and narrower platforms on the sides.

PEAS ON THORN STOCKS (*H. W. T.*).—All the varieties which we know succeed on Thorn Stocks, have already been mentioned by us—viz., Vicar of Winkfield, Louise Bonne of Jersey, Josephine de Malines, Styrian, and Swan's Egg.

WILLIAMS'S CONSERVATORY (*J. W.*).—There is no mistake on our part. It is on page 175 of our last volume, No. 179, August 30th.

PEAR (*Tyro*).—There is no Pear named Vicar of Wakefield. It is a mistake for Vicar of Winkfield.

COTTAGE GARDENERS' DICTIONARY (*Arcaea*).—It is not a new edition, nor does it include any plants introduced during the last seven years.

SPRINGING PEACH TREES—SPURS ON APRICOT TREES (*C. P.*).—You would see in "Doings of the Last Week," that a little notching of the buds by a gentle syringing would be an advantage in dry sunny weather. In damp cloudy weather it is of little consequence. As to the Apricots, the nearer they are to the wall in moderation the better; but we would stay a little until the fruit-buds show more, and then shorten these long spurs, if you can leave enough of buds behind them.

**HEATING SMALL GREENHOUSE (Twickenham).**—For such a small house (8 feet by 5½) a small cast-iron stove, with flat head for an iron vessel of water, would be much the handiest; or a small brick stove set inside of the house. The next best would be a small furnace outside, say 10 inches wide, 12 inches deep, and 18 inches long, and a small flue, say 5 inches wide inside measure, and 7 inches deep, below the tiled floor. The principle of the Kiddean system is just a strong furnace, with a smoke chimney from it, with damper to regulate it, a chamber all round the furnace, and from this chamber an inlet into the house for the heated air, and a lower opening for cold air to keep up the circulation less or more on the Polmaise principle. Practised men can make any mode of heating answer. In such a small house you need have no difficulty with the chamber, but the furnace must be very secure, or you will be troubled with smoke, &c. The small flue below the floor, supposing the floor to be tiles, &c., would be the neatest for such a narrow house. See what Mr. Fish says of such a house in a late Number. Your *Ipomoea Horsfallii* will not succeed in such a house. I. Leair will do so. We would cut neither down, but you may thin out to one shoot. The plants will require pots of from 13 to 15 inches to bloom well in.

**VINES IN BAD CONDITION (A Subscriber).**—We think no gardener makes his case better by dwelling on the failings of his predecessors. It is much better to do that which is right yourself, and never mind what your predecessors have done. Your successful efforts at improving the place under your care will shine the more brightly because undertaken unassumingly. Your first objection is to the road dirt or scrapings. We have seen very fine Grapes grown on Vines in that material alone. You removed two spits of road dirt, and it was replaced with equal quantities of turf, good; hotbed manure, little better than poison—one-fourth would have been ample, and that one-fourth more than we like; half-burnt clay, good as far as it goes, but charcoal would have been better; and lastly, 1 cwt. of manure was added—1 cwt. of boiled half-inch bones would have been preferable. We should have formed the border of three-fourths turves 3 inches thick, chopped with a spade, but neither beaten nor made fine, these being taken from a soil neither strong nor very light, but better the latter than the former, the remainder equal parts of boiled half-inch bones and charcoal. This is a compost very suitable for the Vines, and durable. You took off two spits and put on a like quantity; this did not bring the roots nearer the surface. From three to six inches of compost over the roots would have been sufficient, and a covering of hot dung would have attracted them upwards. Your proceeding is making bad as bad as it was before. Your best course would have been to have lifted the roots and brought them to the surface within half a spit, so that they would have been raised about 1½ foot, and be just 6 inches below the surface of the new border. It would have been better to have done it at once, and not delayed it until another year. The Vines can do no good when two spits of the border can be taken off without injuring the roots; and, as you do not start them until April, you would be acting wisely to get your employer's consent to lift them in March, making the drainage good, and a border 20 inches deep. Spread the roots out, and cover them with from 4 to 6 inches of soil. You have cut half the spurs back to see if they will break nearer the rod. If they do not, which is quite likely, your proposed improvement will be necessary. It would have been better to have trained a shoot or cane from the bottom to replace the old rod. Again, the Vines have been kept nearer the glass, but you have had the irons lengthened to a foot or 18 inches. Sixteen inches is a proper distance to have them from the glass. Your painting the Vines is good. We should think the young Vines will be as unfruitful as the old. A little top air at night is desirable, especially when the Grapes are colouring.

**WHITE-WASHING A GARDEN WALL (L. B.).**—The proposed whitewash would not improve the appearance of your wall. All the good it would do would be to fill up the smaller crevices in the joints and in the face of the bricks, and in this way it would act as a destroyer of moss, and of insects to a certain extent. Its efficacy is increased by adding soot and urine, so as to make it of the consistency of thick paint, applying the mixture with a brush, working it well into every hole and crevice. If it is applied at the temperature of boiling water it would kill many more of the insects' eggs than used cool. Our opinion is that it would not improve the appearance of the wall, but that it would be useful as a destroyer of insects and moss.

**PIGION-HOLES IN CUCUMBER-PIT (Dromio).**—It is necessary to have the inner walls of a Cucumber-pit pigeon-holed, so that the heat from the things may pass into the bed. If the bed is not lined, and Cucumbers are not required early, it is not necessary to have the walls pigeon-holed; but then no linings can be given, and consequently no extra heat afforded when the heat of the bed declines. When the walls are built solid linings placed against them give little heat to the bed.

**ROSE SEED SOWING (Idem).**—The first week in March is a good time to sow Rose seed. Sow in deep pans, well drained, in a compost of rich sandy loam, and plunge in the open ground. The plants may appear in April or May, but the seeds very often do not vegetate until the spring of the second year.

**SCOTCH SNUFF IN PAINT FOR FRUIT TREES (A. B.).**—Scotch snuff is simply powdered tobacco, and that is well known to be one of the best insect destroyers. Your mixture of sulphur, lime, soft soap, clay, and soot, is good, but we should have mixed it with tobacco water to the consistency of paint. Scotch snuff being stronger is considered eligible for the purpose. We do not know what properties resin and dragon's blood possess to recommend them for winter-dressing Vines, &c. We never found any benefit from such nostrums, and we must know what they kill before we use them. For these reasons we employ sulphur, lime, soot, and soft soap, along with tobacco water. The first is a powerful antidote against mildew and red spider; lime, a wholesale destroyer of fungi, is useful in destroying the spores of mildew; soot is the best of all antidotes against the attacks of red spider on account of the ammonia it contains; soft soap, because it is a certain destroyer of the Coccus or scale insect family; tobacco, whether in the shape of snuff, tobacco water, or in the leaf, as it is a certain destroyer of the Aphid family; and clay, because it gives consistency, and smothers many insects by forming a coat over them. Clay also prevents the mixture being so easily washed off.

**SEEDLING CINERARIA (W. L., Eaglescliffe).**—No fair opinion can be formed of three single flowers of any *Cineraria*; the whole plant in flower should be seen. The seedling received has no good properties as a florist's flower, though it may be, as we have no doubt it is, useful, as a decorative plant. The outer being of colour is very irregular, giving a coarseness to the petals, which are much too long. Compare it with a named variety from Mr. Turner of Slough, or Messrs. Smith of Dulwich, and you will soon detect the imperfections pointed out in your own flower.

**FLOWER-BED PLANTING (D. C.).**—We presume that the groups are to be cross-planted, and we have no doubt but that they will look well. As you want criticism, we should not like to have the quarter or group on the left side all pink, or nearly so. Thus, of the seven beds you have two Trentham Rose, four Manglesii, and the long centre bed Golden Chain. With the exception of the whitish foliage of Manglesii, and the yellow foliage of the Golden Chain, the whole colour of the flowers will be pink. What would you say to surrounding your two Trentham Rose with Manglesii, and then filling the four beds, 2, with brown, purple, or blue? We have just noticed that you propose Flower of the Day as a border to Trentham Rose—well so be it. Then you could use Manglesii on the right-hand side, which we like better than on the other side, and on could use Golden Ivy-leaf for No. 7, or *Calceolaria floribunda*. We do not consider that *Alyssum* is good enough for your central bed 7, and you should have a yellow to light up your four beds 6, 6 5 6 of Purple King. The beds would then stand 7, yellow; 5, 5, scarlet, with Manglesii; 6, 6, 6, Purple King, with Variegated *Alyssum* sprinkled through it.

**OVER-HEATING VINE ROOTS (A Market Gardener).**—When we saw your little piece of a leaf, we thought you must either have mildew or thrips, or both. From your account now, we have no doubt you have overheated your Vine roots, and, probably, also the top. We should have liked the shoots to be the length you speak of, after the Vines had been shut up six or seven weeks instead of four. As to the stems outside, we fear you have injured them and the roots much by over-heating. Your hot dung should have been kept away from the stems. Now, you must cool the border, but not over-nakedly expose the stems, and cover them with dry hay or straw. Syringe your house, keep it moist, with a fair amount of air, and remove the covering from the border until the earth is about 70°, and then cover a little. Your processes seem all right, except overdoing the thing. You would see in "Doings of the Last Week," that it was safer to keep heat in by a loose covering, than to use such a mound of hot fermenting matter. The flue, if hot, may have contributed to the mischief, but with a nine-inch wall between it and the border, we lay no great blame on it. We fear the excess of dung has done the mischief, but with care and reducing the heat, we would not yet despair. Are you sure that fresh lime has nothing to do with it? We think the over-heating is the cause. If you lessen the heat and these shoots should be injured, most likely side-shoots will come from the same buds. We shall be glad to know the result, and we are only sorry that the case seems so bad.

**ARDISIA CRENULATA CULTURE (Norfolk).**—This is anything but hardy. It is a native of the West Indies, and requires a cool stove, or a warm conservatory, in winter, though doing very well in a greenhouse in summer. In some warm places it will thrive out of doors in summer—say for three months after the end of June. Its generic name is derived from *ardis*, a spear-head, in reference to the pointed petals of the flowers. The flowers are small, greenish white, and but little attractive to the eye, but are followed by clusters of berries, which, as they approach maturity, vie with the bright red berries of the Holly for beauty. These give the plants a very pretty appearance, and fine masses will be produced on young plants from a foot to 18 inches in height. The plant grows freely in sandy loam, fibry peat, and leaf mould. The more loam is used, the more compact will the plant be, and the closer will be its rings of berries. It is easiest propagated by the seeds, sown on a hotbed, or in pots on a stage in the hot-house; but, as in the case of the Holly and the Thorn, you must wait a good while for their coming up; but after that you can pot off, and the seedlings will give little trouble. Young shoots, slipped off with a piece of last year's wood, root readily in a pot of sandy soil, inserted in a shady place on a hotbed; and pieces of the root will also grow and send up shoots if placed in a similar position. Cuttings will make the finest and quickest-flowering plants, and seedlings are attended with least trouble. Where two or three plants are grown in a stove, seedlings will often be found springing up in other pots from the dropped seeds. This, and the red berries of the *Rivina humilis*, which also blooms in a small young state, are useful for ornamenting dining-tables. The plant will not thrive if the winter temperature falls below from 45° to 50°. It would like a few degrees above 50° better.

**SCALE ON PEAR-SHOOTS (A Reader).**—The scale on the Pear-bark and shoots enclosed, which have been twice dressed with Gishurst compound, one dressing at a strength of 12 ozs., and the second at a strength of 16 ozs. to the gallon of water is, we should think, dead. Your tree is the worst infested with the small Pear scale of any that we have seen. If you get rid of the enemy with half a dozen dressings you will do well; but we fear the dressing is only partially applied, or your Gishurst is weaker than ours. A solution of the Gishurst at the rate of 8 ozs. to the gallon, we find quite strong enough for dressing fruit trees. Half the battle in destroying insects is to dislodge them, and this we do by applying the dressing with a brush, working it well in. We find the brushing dislodge a great many, and the wood looks very clean afterwards. It is astonishing what havoc a brushing with water makes with scale insects. The efficacy of any cure depends quite as much on the mode of application as on the destructive character of the mixture applied. A composition applied as a winter dressing should be used at the temperature of 160°, brushing it well into the cracks and crevices of the bark, care being taken not to injure the buds. One thorough application will do more good than half a dozen partial ones.

**TEA CULTURE.**—A Subscriber would be much obliged by an answer as soon as possible to the following questions. How is the Tea plant best cultivated in India? How soon it comes into produce of leaf for gathering? How long it continues productive? What is the best way of pruning the Tea plant? Ought it to be pruned every year? How many plants on an acre? What is a good average crop off an acre? What is the best work on Tea cultivation? (*Inquirer*).—If you write to Mr. Smith, Curator, Botanic Gardens, Kew, he will tell you what information you can obtain there. There is "An Essay on the Cultivation and Manufacture of Tea in Java," translated from the Dutch by Dr. Horsfield. If we required the best information on the subject we should apply in India to the Curator of the Saharunpore Garden.

**BREDDING GERANIUMS (A Lover of Flowers).**—The two-coloured section of Geraniums you speak of do well out of doors in a warm place and a dry season. In the wet climate you speak of we would not depend on them, as the blooms run, and look washy.

**MOISTURE IN AIR OF FRERNERY (S. C. O.).**—There are many hygrometers which indicate the amount of moisture in the atmosphere. Try Casella's Garden Hygrometer. Its price is 13s. 6d., and Mr. Casella lives in Hatton Garden, London.

**WINTERING CALADIUMS (J. A. P.).**—These are best kept in the pots in a stove seldom below 60° at night. In such a structure, with the pots standing on a damp floor, the roots may be kept safely. The pots will absorb a little moisture from the damp floor, communicate it to the soil, and so prevent the roots becoming farinaceous, and consequently decaying when placed in heat and moist soil. With a soil neither very dry nor wet—one apparently dry yet containing a little moisture in consequence of the pots being placed on a damp floor (or failing such a position, a slight skiff from the svinge at the time of sprinkling the house occasionally, will do as well), and a temperature of 65°, there will be no difficulty in keeping Caladium roots through the winter.

**DESTROYING MOSS ON CROQUET GROUND (E.).**—Now is the time to do it, for at this season mosses flower or attain their greatest perfection. Whilst the ground is wet or soft, rake it with a long, sharp-toothed rake, working it backwards and forwards sufficiently to bring the moss to the surface, and disturb that remainder considerably. Clear away the moss so brought up, and let the ground alone for a fortnight. Early in March repeat the operation; and about the middle of that month apply a dressing of rich compost, which may consist of any old rubbish well decomposed, adding one-sixth of fresh lime. Mix the lime with the compost a few days prior to spreading it over the ground. A sprinkling of water may be necessary to make the lime fall. Cover it with the compost. Spread this on the ground at the rate of 200 barrowloads per acre, passing it through a three-quarter-inch sieve, to save the trouble of stone-picking. Rake it evenly over the surface with a wooden rake, and, when dry, sow *Festuca ovina*, 6 lbs.; *Festuca duriuscula*, 3 lbs., or 6 lbs. if the grass is to be mown with a machine; *Cynosurus cristatus*, 6 lbs., and *Trifolium repens* and *T. minus*, 3 lbs. each, omitting the last if the ground is of a wet nature. If the situation is shaded by trees sow 3 lbs. of *Poa nemoralis* instead of *Festuca ovina*. The above quantities are sufficient to renovate an acre. After sowing, the ground may be lightly raked, and then well rolled, and twice weekly. If you could spare the use of the ground for a week or two in May, a dressing with soot, in damp weather, would do much towards ridding the lawn of the moss. The cause is a poor soil and damp bottom; the remedy, an improved state of the soil and more herbage. Wood ashes are good, also salt; but it takes as much salt to kill moss as it does to destroy grass. Have nothing to do with it. By proceeding as above recommended you will not be able to use the ground so early, but you will be well satisfied with the improvement in the firmness of the lawn.

**TRAINING MACRANDRAS—HARDINESS OF AGATHEA CECILESTIS (A Subscriber, West of Ireland).**—You may cut the *Maurandya* down to a foot or so high, and it will probably shoot afresh, but we would strike some of the young shoots. They strike readily in sandy soil on a hotbed. When the plant makes fresh shoots stop these when a foot high; this will encourage side-shoots. Train these evenly over the wall, and stop them at every foot of their height if they appear disposed to grow without making side-shoots. If the shoots come too close together thin them out, and any straggling shoots may be cut out, otherwise it is one of the neatest-growing of climbers, very close-habited, and free blooming. It does well in a compost of loam and leaf mould, either as a greenhouse plant or a half-hardy climber suitable for covering trellises. Train to poles, or plant against any support in sheltered situations in the flower garden during the summer months. *Agathe cecilestis* is a half-hardy, variegated, bedding plant, and is not hardy, so far as we know, anywhere in the kingdom. We think it would not prove hardy even in the mild climate of Ireland.

**STRIKING DAHLIAS (Idem).**—You may place the roots on a gentle hotbed in the beginning of March, and when the shoots are from 3 to 6 inches long take them off with a little of the old root to each, and put them in pots sufficiently large. Return them to the hotbed for a fortnight, barden off, protecting in a frame or greenhouse until the end of May, and then plant out. Your plan of raising from cuttings without any portion of the old root is a good mode of propagating the new and rare sorts but the plants are usually small, and flower at a later period. They would flower sooner by potting each root in the first instance, and as the shoots appear removing them all but one. This will be very strong, and may be planted out with its flower-buds nearly expanded. We like to plant a good strong plant, and have flowers early. Small plants from cuttings, though late, usually give the best flowers. The main points to be attended to in order to have Dahlias early, is to begin in good time, and to have plants strong and well hardened off prior to planting out. Evergreen Oak may be increased by layers, but they are best raised by sowing the acorns or seed. March is a good time to sow them.

**EDDLERWEIS (M. A. E.).**—In answer to our inquiry last week relative to the botanical name for the German title for an alpine plant we have received replies from Lady S. I. Thomas, and A. H. Taylor, all three agreeing that it is *Gnaphalium leontophyllum*, and all recommending a little work on alpine plants, published at Munich, entitled, "Die Alpen Pflanzen Deutschlands und der Schweiz." The more modern botanical name of the plant is *Leontopodium helveticum*, and a very good portrait of it is in the "Botanical Magazine," t 1958. Our correspondent "M. A. E." had sown seeds of it, and treated them very judiciously by plunging "the pot in which the seeds are sown under a north wall, beneath the snow, as it is difficult to find any dark place cold enough," but she wishes for some positive directions. The following is what Mr. Fish says on the subject. "I believe *Leontopodium helveticum* is the same as *L. vulgare*, a native of the mountains of Switzerland and Austria. It is a number of years since I have seen it. I am not now sure, but I think I saw a pot of it among the alpinees at Drumcondra. I think you could not do better than consult Mr. Donald, of Hampton Court. I recollect seeing a nice little patch of it from 4 to 5 inches in height, with its pretty yellow starlike flowers, in a sheltered place in a rockwork. It stood in a hollow, yet some 4 feet from the ground. It was growing in sandy peat, well drained. The four stones that stood like little cliffs round it had a space left between each, so that there could be no stagnant moisture. In winter some evergreen boughs were stuck round it. No protection whatever would be necessary could we secure snow before frost. I recollect of the plant chiefly as an alpine, grown in a pot half filled with drainage, and set up to the rim among rough clinders in winter, and covered with the glass of a frame. In severe frost, without snow, a little protection would be given to the glass, as in the case of other rare alpinees. It is propagated by divisions in spring, placed in sandy peat under a hand-light; and seeds may be sown at the same time in a pot half filled with rough drainage, then an inch of sand, and then sandy peat, the upper layer fine and within half an inch of the rim. On this scatter the seed, slightly press, and cover with a square of glass; shade with a little paper until

the seeds are up, then give air and light gradually, and prick off in the usual manner. These, however, are chiefly recollections, and, as stated above, I would advise applying to Mr. Donald as the most likely person to afford information as to this pretty rare plant."

**SUMMER TREATMENT OF CYCLAMENS (M. D.).**—The Auricula-stand figured in No. 201 would answer admirably for Cyclamens in summer, more especially if the roof were of glass, as you propose. It should be placed so as to have a northern aspect. Tubers, when exposed to the full influence of a hot summer's sun, as yours were, are liable to become blind, or not shoot from the crown, but they usually form a spur at the lower part of the root, on which the leaves and flowers are produced. We have not suffered from mice eating the tubers, nor is it likely, for the fresh roots are bitter, acrid, and burning; but yours, baked as they were, might have become farinaceous, and they are then harmless. Rabbits are still more unlikely to have nibbled them. Dr. Hogg states, in his "Vegetable Kingdom," that "M. de Luca found four grains of the juice, injected into the trachea of a rabbit, caused it to die in convulsions in the course of ten minutes."

**FINE-FOLIAGED PLANTS (Liverpool).**—All but the first two, which, however, are decidedly ornamental, though not what are called fine-foliaged.

**NAMES OF FRUIT (R. A. H.).**—*Apples*.—1, Damelow's Seedling; 2, Golden Russet. *Pears*.—1, Beurré d'Areberg; 2, Beurré de Rance.

**NAMES OF PLANTS (T. A Subscriber).**—Apparently a distorted *Lastrea dilatata* (*Pentandria*).—1, *Selaginella Galeotti*; 2, *Selaginella Martensii*; 3, *Asplenium flabellifolium*; 4, *Asplenium bulbiferum*. (*Rock*).—1, *Cyrtium falcatum*; 2, *Lastrea Filix-mas cristata*; 3, *Lastrea indivisa* apparently, but there is no fruit; 4, *Nephrolepis tuberosa*; 5, *Oncidium japonicum*; 6, *Pteris scaberula*. Such specimens—tips of fronds—are the worst you could send. (*Filix-mas*).—1, *Geranium Golden Chain*; 2, *Pteris serrulata*; 4, *Pteris hastata*. (*Ignoramus*).—It is a Moss, and one of the *Hypnum*—we think *H. splendens*. (*H. E. H.*).—1, *Litochia vesperilionis*; 2, *Oncidium lucidum*; 3, *Asplenium compressum*; 4, *Nephrolepis tuberosa*; 5, *Asplenium bulbiferum*; 6, *Nephrodium molle corymbiferum*. (*E. J. H.*).—1 and 2, both *Asplenium lanceolatum*. (*Norbiton*).—1, *Pteris tremula*; 2, *Phlebodium arcuatum*. The Apple is Lewis's Incomparable.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### JOINT-STOCK POULTRY COMPANY.

To say I entirely agree with your opinion and yet I differ, seems a paradox which I will, however, satisfactorily explain hereafter. I doubt not that, had I not been compelled by circumstances to notice your first leader on the above subject, your subsequent remarks might probably have been equally in harmony with my views. It happens, however, that you have been, and still are, publishing my "Treatise on Poultry-keeping in a Commercial Point of View," which, judging from the number of letters I have received since the publication of your leader, requesting a prospectus with a view to taking shares in the Company, seemingly leads many persons to infer that I am the promoter of the Company alluded to in your article. I beg to inform your readers that I have not the slightest knowledge of that Company or its promoter. It is true that I have had offers from many persons to take shares in a company which I might form under the Limited Liability Act, to carry out my system of poultry-keeping and egg-preserving; but my invariable answer has been, that if a company were promoted by any other party I should be happy to contribute my experience and professional services to the success of the undertaking, but that I could not afford to become its promoter.

Now, what I agree with you in is this:—That were a company formed for poultry-keeping on a large scale according to the prevailing system, it would prove a certain failure, and this for the reasons you so justly point out in your leader; so far, therefore, I quite agree with you, and aware of your great experience and knowledge in all that relates to the advantages Joint-Stock Companies have conferred on the farming interest, by executing drainage works and building homesteads at a rental charge, by letting machinery on hire, by the manufacture of artificial manure, &c., I doubt not that your subsequent remarks on the joint-stock principle applied to poultry-breeding would have been equally identical with my views. In the first place, the Limited Liability Act, which has done more for the prosperity of the country than any preceding Act, although it has in many instances proved a limited and determinate loss to shareholders, has yet been the means of blessing us with the practical use of those admirable inventions which add so much to our comfort, convenience, security, and national prosperity, and which no private persons, however vast their fortunes, could possibly have carried out. In fact, the very essence of Limited Liability is to assist improvements to be practically realised without much individual risk. I have seen too many failures of

most promising undertakings to advise any person to invest his all in any scheme, however promising. Yet I cannot shut my eyes to the advantages that would be conferred on the country by a Joint-Stock Company for poultry-breeding and egg-preserving on scientific principles, or, as some may call it, by artificial means; and taking your statement that we import at the rate of one million of eggs daily, with an increasing consumption, as a basis, there would seemingly be room enough for a score of companies.

I will not enter into details as to how such concerns ought to be managed, but I entirely agree with your concluding remarks, that poultry kept in very large numbers together, and left to roam in all weathers, are subject to disease, which soon spreads, and profit disappears.—GEO. K. GEYELIN, C.E.

### THE POULTRY CLUB.

LEST any misconception might be placed on silence, I wish to state, in reply to your correspondent "TIMID EXHIBITOR," and to the remarks in your "Letter Box," that it is not the intention of the Stewards of the Poultry Club to enter into any discussion on its merits or constitution through the columns of the press.

The circular sent out to upwards of four hundred exhibitors, with a view to make its objects more generally known, will have informed your correspondent that the "Hon. Secretary will be happy to give information on all subjects connected with the Club;" and I now repeat that all courteous communications will be promptly and fully replied to, but under no circumstances will anonymous letters through the press, or attacks consisting of vague insinuations, be considered.

The proceedings of the Club will be published from time to time; a list of its members and officers, a statement of its objects, and, after the next general meeting, a copy of its bye-laws, which are now in course of republication, will be at the service of any one applying for them.

It is the wish of the promoters that the Club stand or fall on its merits. Its numbers are daily increasing, and its officers are fully determined that no amount of individual cavilling, *ex parte* statements, or editorial cold water, shall deter them from carrying out what they consider its legitimate ends. I may add that the discountenancing of dealer judges is one of their principal objects, and they see nothing in their list of judges at variance with it.

It was in your columns that this great reform was first publicly advocated, and on that point at least the officers of the Club feel sure of your sympathy.—FRED. WM. ZURHORST, *Hon. Sec. (pro. tem.)*

### NANTWICH POULTRY EXHIBITION.

THIS Exhibition is generally admitted to be the closing show of the season, and, although limited to the immediate locality—viz., a circle of thirteen miles from Nantwich—the competition, in the majority of the classes, is such as would put to the blush many meetings of far higher pretensions. The Nantwich Show is consequently regarded with much interest among poultry amateurs, and never lacks a large number of visitors. Nothing is ever left undone that can tend to the comfort of the birds exhibited, or the pleasure of those persons who may attend the Show, by the gentlemen who officiate on the Nantwich Committee; and the popularity of this Show is also very greatly enhanced by the untiring attention of Mr. Edwin Rhodes, as Hon. Secretary. Quietude, order, and regularity are, therefore, universal throughout the whole proceedings. Some of our most noted breeders of exhibition poultry residing within the limits to which competition is restricted, scarcely any class seems to differ materially from those met with at all other local shows; and the Game fowls raised round Nantwich are noted for being excellent, their reputation in the cock-pit being established for a long series of years prior to the institution of our earliest poultry exhibitions. These birds still remain universal favourites in the district; and, consequently, it is, by no means uncommon for some of our most noted breeders of Game fowls to canvass this neighbourhood closely in search of specimens for the show-

pen. For birds equal to the requirements of such parties, therefore, a very liberal price is frequently obtained. Such encouragement naturally fosters a spirit of emulation: and hence it is that, year by year, the competition in these classes invariably increases. The variety of Game fowls most esteemed about Nantwich is the Brown Reds. This is easily accounted for from the fact that they are known to be the hardest fighters of all Game fowls.

This neighbourhood is also famous for its strain of Red Pile Game fowls; and yet another breed of very hard-feathered Game cocks are to be commonly met with, exhibited by the Nantwich breeders as Black Reds, but they are far too dark-coloured for show fowls of that feather. They have every appearance, however, of being birds of great power and courage. The *Spanish* classes at Nantwich were indisputably good. We regretted to see, however, in a highly commended pen, decidedly the best cock shown with all the serrations of the comb frosted completely off, leaving him as useful as before for stock purposes, but ruining him for ever as a show bird. Proprietors of highly-bred Spanish fowls cannot possibly be too careful in giving their best birds due protection from intense cold.

Following the order of the catalogue, *Aylesbury Ducks* stand next, and a finer collection is rarely met with; the *Rouen Ducks* were also very good. In *Turkeys* the birds, individually considered, were perfect, but a proper regard to matching, as to feather, seemed disregarded. The class for *Geese* comprised only three pens, a beautifully-feathered pair of *Canadians*, and two unusually good pens of the *Emden* variety.

All the *Dorkings* were good, and fit to compete at much larger meetings.

In *Cochins*, Mr. Tudman, of Whitchurch, seems to have absolutely frightened all competition out of the field. That gentleman's well-known birds were shown in excellent condition, and well-merited the prizes they obtained; but we do hope another year to find some enterprising resident amateur or another throwing down the gauntlet to prevent a positive "walk over."

The "Selling class" was good, and several pens changed hands.

The *Game* fowl classes generally were quite sufficient to sustain the high repute of the district, numbers of the *Brown Reds* being as close an approach to perfection as could well be supposed. The competition in this variety has been rarely equalled, and a number of these birds speedily changed ownership. We regretted much to see a very excellent pen, and a prizewinner, subjected to the loss of its premium through an improper entry as to ownership. Why cannot men either observe the rules laid down or decline competition? The attempt to thus covertly take prizes is a dangerous experiment in every case, as facts among the non-successful, however carefully concealed, will always ooze out, and subsequent exposure cannot bring with it anything covetable in the retrospect, as regulations must be enforced. The winner of the Nantwich Victuallers' silver cup, for the best Game cockerel, was a splendid specimen of *Brown Red*, although barely recovered from "dubbing."

The *Hamburgs* were many of them good, whilst the *Polands* were of extreme merit; here, however, as in the *Cochins*, Mr. Heath, with his capital collection of *Silver-spangled* ones, seems to frighten all rivals away. Some very good *Game Bantams* were shown, both *Black Reds* and *Duckwings*. The entries for the "Any other Variety class" were six in number, from four different exhibitors, yet, singularly enough, every pen consisted of *Brahmas*. They are justly prized about Nantwich as winter layers, for pullets of this variety rarely discontinue laying even should the weather become suddenly severe.

The collection of *Pigeons* was not so large as usual, but embraced many perfect pens. Among the most praiseworthy specimens were some *Dun Carriers*, an excellent class of *Dragons*, and *Nuns* as near perfection as could be hoped for. Among the extras were some very good *White Doves* and well-conditioned *Lahore Pigeons*.

The collection of *Singing Birds* was good, and in this portion of the Show was one of the most beautiful specimens of the *Sky-lark* ever, perhaps, exhibited.

*SINGLE GAME COCKS* (Any colour).—First, E. Bowers, Nantwich. Second, T. Burgess, Burleydam. Third, J. Walley, Larden Green. Fourth, H.

Vickers, Wyburnury. Highly Commended, G. Williams, Acton; A. Robinson, Wrenbury. Commended, J. G. Kenyon, Maccfen; R. Ashley, Nantwich; J. R. Court.

**GAME (Black-breasted Reds).**—First, J. Smith, Winsford. Second, A. Phillips, Winsford. *Chickens.*—First, — Miller, Wyburnury. Second, J. Heath, Nantwich. Third, J. Grocott, Bunbury. Commended, J. M. Piggott, Stapley; T. Moore; A. Heath, Winsford; G. Williams.

**GAME (Brown-breasted Reds).**—First, T. Whittingham, Batherton. Second, W. Galley, Nantwich. *Chickens.*—First, T. Burgess, Burleydam. Second, E. Bowers, Nantwich. Third, W. R. Walton, Wyburnury. Highly Commended, T. Edge, Winsford; A. Heath, Winsford.

**GAME (Any other variety).**—First, R. Ashley, Nantwich. Second with-held. Commended, R. Roberts Ravensmoor. *Chickens.*—First, R. Crewe, Burland. Second, J. Padley, Nantwich.

**GAME HENS (Any variety).**—First, W. Galley, Nantwich. Second, W. Fisher, Ravensmoor. Highly Commended, J. Thursfield, Audlem; W. Galley; H. Oakes, Nantwich. Commended, T. Dodd, Broad Lane; J. Dodd, Broad Lane.

**BRAHMA POOTRAS.**—First, W. Woolley, Bunbury. Second, W. B. Etches, Whitechurch. Commended, J. Heath, Nantwich.

**SPANISH.**—First, J. Dean, Winsford. Second, R. Hulse, Winsford. Highly Commended, W. Woolley, Bunbury; J. W. Holding, Nantwich. Commended, W. Woolley. *Chickens.*—First, J. Heath, Nantwich. Second, W. B. Etches, Whitechurch. Commended, Miss Hill.

**DORINGS (White).**—First, Mrs. Tollemache, Dorfold Hall. Second, J. Platt, Swanlow.

**DORINGS (Any other colour).**—First, T. Burgess, Burleydam. Second, Rev. E. Duncombe, Bathomley. *Chickens.*—First, T. Burgess. Second, Mrs. Broughton, Wistaston. Commended, Mrs. Tollemache, Dorfold Hall.

**COCHIN-CHINA (Cinnamon, Buff, and Partridge).**—First and Second, E. Tudman, Whitechurch. *Chickens.*—First and Second, E. Tudman. Highly Commended, J. Withinshaw, jun.

**COCHIN-CHINA (Any other colour).**—First, J. Dutton, Bunbury. Second, J. Dodd, Minshull Vernon. Highly Commended, G. Williamson, Nantwich. *Chickens.*—First, J. Dodd. Second, G. Williamson. Highly Commended, J. Dutton.

**COCHIN-CHINA COCKS (Sweepstake).**—Prize, J. Withinshaw, jun., Nantwich.

**POLANDS (Any variety).**—First and Second, J. Heath, Nantwich. *Chickens.*—First and Second, J. Heath.

**HAMBURGS (Gold or Silver-pencilled).**—Third, J. Wainwright, Norton. Commended, W. R. Walton, Wyburnury; J. Hornby, Minshull Vernon.

**HAMBURGS (Gold or Silver-spangled).**—First, S. Armstrong, Radmore Green. Second, J. Hitchenon, Moulton. Highly Commended, S. Armstrong.

**GAME BANTAMS.**—First, T. Burgess, Burleydam. Second, W. Griffiths, Nantwich.

**BANTAMS (Any other variety).**—First, G. Williamson, Nantwich. Second, T. Butler, Middlewich. Commended, J. G. Kenyon, Maccfen.

**GAME BANTAM COCKS (Sweepstakes).**—First, T. Marsh, Nantwich. Second, W. Griffiths, Nantwich. Third, T. Stanyer, Nantwich. Highly Commended, W. Griffiths. Commended, T. Stanyer.

**GAME COCKERELS.**—First and Cup, T. Whittingham, Batherton. Second, W. Galley, Nantwich. Third, P. Judson, Nantwich. Fourth, T. Burgess, Burleydam. Highly Commended, J. Wilkinson, Nerbury; H. Oakes, Nantwich. Commended, W. Hope, Nantwich; J. Lewis, Nantwich; W. Clarke, Burland; R. Ashley, Nantwich; A. Heath, Winsford.

**TURKEYS (Any colour).**—First, J. Edwards, Doddington Mill. Second, Mrs. Tollemache, Dorfold Hall. Highly Commended, T. Burgess, Burleydam.

**GEES (Any colour).**—First, Miss Hill, Wistaston. Second, W. Furnival, Norton. Highly Commended, J. Thursfield, Audlem.

**DUCKS (Aylesbury).**—First, Mrs. M. Hornby, Swanlow. Second, J. Grocott, Haughton. Third, J. Platt, Swanlow. Highly Commended, R. Cornes, Hurlston. Commended, G. Richards, Whitechurch.

**DUCKS (Rouen).**—First, J. G. Kenyon, Maccfen. Second, T. Burgess, Burleydam. Third, H. Prince, Nantwich.

**DUCKS (Any other variety).**—First, Master J. Hill, Wistaston. Second, E. Bowers, Nantwich. Highly Commended, Mrs. Bateman, Chorley.

**SELLING CLASS.**—First, C. Barnett, Blakenhall. Second, W. B. Etches, Whitechurch. Commended, R. Hulse, Winsford; J. Heath, Nantwich.

**HEAVY RABBITS.**—Prize, S. Davies, Nantwich.

#### PIGEONS.

**CARRIERS.**—First and Second, W. Woolley, Bunbury.  
**DRAGONS.**—First, W. Woolley, Bunbury. Second, W. Cliff, Nantwich. Highly Commended, W. Cliff; W. Woolley.

**POWTERS.**—First, J. Dutton, Bunbury. Second, J. Withinshaw, Nantwich.

**BARBS.**—First, W. Woolley, Bunbury. Second, J. Hockenull, Nantwich.  
**NUNS.**—First and Second, J. Dutton, Bunbury.

**TUMBLERS.**—First and Second, T. Cawley, Tarporley. Highly Commended, H. Ruscoe, Nantwich; J. Withinshaw, Nantwich.

**FANTAILS.**—Prize, C. B. Davies, Eardswick Hall.  
**JACOBINS.**—Prize, J. Hockenull, Nantwich.

**TRUMPETERS.**—First, J. Withinshaw, Nantwich. Second, A. Garnett, Nantwich.

**OWLS.**—First, G. Nixon, Soud. Second, A. Garnett, Nantwich. Highly Commended, W. Ruscoe, Nantwich; G. Nixon, Soud.

**TURBITS.**—First, — Hockenull, Nantwich. Second, J. Withinshaw, jun.

**VARIETIES.**—First, J. Dutton, Bunbury. Second, J. Hockenull.

**DOVES.**—First, J. Cooper, Nantwich. Second, J. Hockenull, Nantwich. Highly Commended, J. Hughes, Audlem; R. Hughes; J. Chesters, Nantwich.

#### SINGING BIRDS.

**CANARIES (Yellow).**—First and Second, S. Williamson, Nantwich. Highly Commended, J. Lockett, Nantwich.

**CANARIES (Buff).**—First and Second, S. Williamson, Nantwich. Highly Commended, H. Prince, Nantwich.

**CANARIES (Any other variety).**—First, S. Church, Nantwich. Second, S. Williamson, Nantwich. Highly Commended, H. Prince, Nantwich.

**C. LINNETS (Brown).**—First and Second, S. Williamson, Nantwich. Highly Commended, S. T. Silver, Norton; D. Robinson, Nantwich.

**GOLDFINCHES.**—First, R. Williamson, Nantwich. Second, D. Robinson, Nantwich. Highly Commended, D. Robinson; R. Williamson.

**SKYLARKS.**—First, T. Williamson, Nantwich. Second, C. Sutton, Nantwich. Highly Commended, J. Willett, Nantwich; T. Williamson.

**BULLFINCHES.**—Prize, H. Hope, Nantwich.

The Poultry was judged by Mr. Edward Hewitt, of Sparkbrook, near Birmingham; the Pigeons by Mr. Charles Cotten, of Crewe; and Mr. Charles Voules, of Chester; and the Singing Birds by Mr. John Robinson, of Manchester.

#### PIGEONS AT THE BRADFORD SHOW.

The collection of Pigeons was most unusually attractive; nearly two hundred pens, divided into twelve classes, competed, and comprised most of the choicest specimens to be met with. Owing to the severe storm Mr. F. G. Stevens's birds were absent.

The Carrier class was a large one. Mr. Else's first-prize Blacks (which also secured the silver cup for the best pair of Carriers, Powters, or Tumblers), were good, the hen being remarkably fine. Mr. Colley's second-prize pen of Blacks contained a good hen. Messrs. A. Pinto Leite, and Eden received high commendations for extremely good representatives, the Duns shown by both being of special merit.

The Powter class was not particularly strong, with the exception of the prize birds. Lengthy well-shaped Blues were first, and very good Reds second.

Almond Tumblers formed a capital class. Mr. Else's excellent coloured pair were first, and Mr. Ford second, with fine birds.

In Tumblers, Any other Variety, Mr. Eden's wonderful Black Mottles were first, and a beautiful pair of Kites second, Black Mottles, Kites, and Blue Beards, received notice.

Barbs mustered strongly. Mr. Haansbergen added another to his triumphs in this variety with his well-known Blacks. Good Reds were second.

Owls formed a nice collection. Fine Blues were first, and Whites (both Foreign) were second.

In Turbits good Silvers, evenly marked and in capital condition, took both prizes.

Fantails were well represented. The first prize went to Whites, the second to good Blues. Several excellent pens received high commendation.

The Jacobin class was one of the best in the show. Mr. J. T. Lawrence, however, completely outdistanced competition with his extraordinary Yellows, and most deservedly obtained both prizes as well as the silver cup for the best pair, excepting the first four classes previously named. Blacks and Reds were highly commended.

Trumpeters were good, Mr. Robinson's first-prize Black Mottles being particularly noticeable. Mr. Oates had his accustomed position with good Whites.

In Any other Variety the Rev. C. Spencer's beautiful Swiss Pigeons were again first, and Satinettes, second. Blue Runts, Black Spots, Black-headed Nuns, White Dragons, Victorias, and Yellow Magpies, all very choice, received notice.

The Selling Class was large and diversified. A handsome pair of Red Magpies were first, and Blue Dragons second.

#### BRAHMA POOTRAS AT THE BRADFORD EXHIBITION.

ALLOW me to ask respecting the Brahma Pootra class at the last Bradford show. I see in your journal the awards in the class named, and in the prize and class list sent to me no such class is named. Being an exhibitor in that class, although not at Bradford, I should have been there had I known there was such a class. I shall feel greatly obliged by information respecting it.—J. WRIGHT, Woodbridge, Suffolk.

[We have made inquiries and find that inserting a class for Brahma Pootras was an after-thought, and we have seen a printed schedule, which was sent before the show, with the prizes to be given for Brahma Pootras inserted in MS. by one of the secretaries. When such a change is made a committee had much better advertise the change. It is only fair to the exhibitors, and for the advantage of the Society, besides avoiding unpleasant suspicions of the motives of the committee.]

## A HOME FOR BIRDS.

CAN any of your readers inform me what I am to do to induce Bullfinches to come and stay in my garden? I have read in the pages of "Cornhill," that if proper arrangements are made to suit the habits of birds, they will come and take up their abode with you. In addition to the Bullfinches, I should like to have a few Thrushes, and Peggy-whitethroats, as occasionally they do pay me a visit. What sort of meat should I provide? Could I make places that suit them to build in, guarding them against the predatory incursions of cats, &c.? I take the precaution now of placing food for them, but the Sparrows take the lion's share. The Sparrow is an impudent bird, he comes occasionally before the Thrush when he is regaling himself, stretches out his neck, and stands bolt upright, as much as to say, I am as big as you. I keep in an old ivy a covey of Sparrows, numbering something like three score; but I should prefer a more melodious note than theirs, if by any means I could induce songsters to stay with me. Probably some of your many readers can suggest a means which, whether successful or not, I shall be glad of.—AMATEUR.

## SWARMING VERSUS NON-SWARMING.

"J. E. B." and "A RENFREWSHIRE BEE-KEEPER" have taken up the subject of the advantages derived from swarming and non-swarming hives; and in looking over my notebook for 1864 I find the following facts relative to two hives, the one swarming and the other not, which may be a little interesting to some of your readers.

No. 1 I will name the non-swarming hive, and No. 2 the swarming one.

On the 25th of February I examined my hives, and found No. 1 seemingly dead, but it resuscitated: bees saved, about 1 lb. No. 2 was in good order, about three parts full of comb, and bees about 2½ lbs. Both hives fed, but there was no breeding till the 1st of April. They then continued to make a steady improvement till May 17th, when No. 2 swarmed. The weather getting cold, they remained inactive till July 1st. A second swarm came off No. 2 on May 28th, and it was hived; and both swarms had to be kept alive by feeding till the 1st of July.

Weighed hives on the morning of July 6th. No. 1 weighed 25 lbs. gross; No. 2, 20 lbs. 1st swarm 18 lbs., 2nd swarm 12 lbs. Weighed them again on the evening of the 8th: No. 1 weighed 54 lbs. making the enormous weight of 29 lbs. in three days. No. 2 weighed 22 lbs.; 1st swarm 22 lbs., 2nd swarm 14 lbs. I pass on now to July 29th, when No. 1 weighed upwards of 100 lbs. No. 2, 30 lbs.; 1st swarm, 34 lbs., 2nd swarm 18 lbs. Honey taken from No. 1, First-class honeycomb, 34 lbs.; second-class, 26 lbs.; total, 60 lbs. No honey from No. 2.

August 2nd took them to the heather. The whole of them had by this time come back in weight a few pounds, as is always the case when the honey-gathering ceases.

I pass on to September 13th, when the hives were brought home. I may mention that from August 29th to September 13th they had decreased in weight from 5 to 12 lbs. By this time No. 1 weighed 90 lbs. No. 2 weighed 68 lbs.; 1st swarm 68 lbs., 2nd swarm 48 lbs. Honey taken:—No. 1, 41 lbs. first-class comb. No. 2, 18 lbs.; 1st swarm 18 lbs., 2nd swarm 13 lbs.; total, 49 lbs., leaving three good stocks averaging 45 lbs. gross weight; whereas in No. 1 one stock is left at 50. Total honey taken from No. 1:—July 29th, 60 lbs.; September 13th, 41 lbs.; total, 101 lbs. From the foregoing it will be seen that No. 1 exceeds No. 2 by 52 lbs. of honey, notwithstanding the unfavourable circumstance it was placed in at the beginning, although No. 2 has the advantage of having two stocks more, and their extra weight will in some measure make up for their deficiency of honey.

It will be seen that in some cases the swarming hives have the preference—that is, where there is a long continuance of fine and honey-making weather; but without a remove, and placed in a locality such as ours, in general there is little if anything to be had from swarming hives; and as means are always taken to insure a succession of stocks, no one will for a moment hesitate to say that the depriving system is the best, not to speak of the superior honeycomb. And further, it is to be remarked that there is

little danger of queens getting aged and effect through non-swarming; often are they dethroned in the first year, and seldom do they survive longer than the second, not from age, but because young queens are brought forward and a new princess installed. This can only be proven by taking care every spring or autumn to become acquainted with every queen in the apiary. This every apiarian should do, marking their several appearances so that he may be able to trace them to the end. The oldest queens are always to be found in hives that have swarmed. I have known hives nine years old that never swarmed doing well, although I make it a rule to have combs no older than two seasons. Such a length of time without any casualty occurring proves that queens are dethroned.—A LANARKSHIRE BEE-KEEPER.

## BEE-KEEPING IN DEVON.—No. XXII.

## A GENIAL DAY—MY LAST GLIMPSE OF FOUL BROOD.

WEDNESDAY, the 8th inst., may certainly be deemed the first spring-like day we have had. Although the sun remained veiled in clouds; the calm western breeze was mild and genial, and the temperature so high that my bees, long close prisoners during the late frosts and more recent rains, availed themselves of it to the fullest extent, filling the air with their most sweet music. Few sights and sounds are more congenial to the eye and ear of the enthusiastic apiarian than those which present themselves on a day like this, and I accordingly spent several hours in my garden delightedly watching, tending, and assisting my little pets to the utmost of my power.

How busy they all appear, and how beautiful are the Ligurians! Beauty is, we are told, only skin deep, but assuredly it is not to be despised. Look for instance at these two hives standing side by side, and compare for one moment the golden, glittering Italians with their modest dark brown, not to say black, British brethren, and declare if it be possible not to concede the *pas* to the brilliant foreigners, whose lithe and agile movements seem to accord so well with the splendour and firefly-like radiancy of their attire.

The first question which intuitively suggests itself to the apiarian is whether pollen is being collected—pollen deemed especially the food of the nurslings, but probably no less essential to adults. Let us watch and wait. We have not long to exercise our patience—there it is, and plenty of it, not carried in in minute quantities by stray individuals, but full loads by several at a time. What is the source from whence it is derived? So far as we can see, the *laurustinus* is the favoured flower; there may be a few loads of snowdrop or crocus pollen, but the *laurustinus* is undoubtedly in the ascendant.

Hallo! whence spring all these yellow-jackets gleaming like crocuses in a garden border among the ordinary black population of the hive? True that in October last I exchanged the black mother of this colony for a yellow queen but I had no idea she would so early have commenced her business in a hive only partially furnished with combs as to produce numbers of young bees by the 7th of February.

Thus much, then, was ascertained by observation of the hives' exteriors. Next came the all-important question of the supply of food. A Salter's balance speedily decided that most stocks were very light, and at this no one need be surprised. Where the multiplication of colonies is pushed to the uttermost we may bid farewell to the honey harvest, and this was so much my case last year that my bees have been dependant upon artificial food for their winter support. In "our Journal" of December 13th I related how I had lost a good stock from the unexampled rapidity with which its artificial supply had become exhausted. This is the only loss I have sustained out of a total of twenty stocks, but having no fancy for its repetition, I at once set to work to take advantage of the fine day by supplementing in the readiest manner the fast dwindling contents of the store cells. And this is the way I accomplished it.—Taking an empty comb, I laid it on its side and slowly poured syrup into it from a jug held some 18 inches above it. When the minute stream, by falling from this height and being directed to all parts of the comb, had filled it on one side as completely as possible, I placed it in an upright position, in which, having been allowed to drain, it was at once substituted for an

empty comb taken from one of the light stocks. This comb having then been filled on one side was substituted in like manner for an empty one in another hive, and the process was continued until the approach of evening put a stop to further proceedings. This plan had the additional advantage of enabling me to ascertain by ocular inspection that none of my colonies was in imminent danger of starvation, since all possessed more or less sealed food. It will readily be understood that I filled the combs on one side only on account of the quantity which would have run out had I inverted them with the view of filling the opposite cells. I could not, however, help smiling as I placed comb after comb in the hives, each weighted on one side to the utmost limits of possibility and perfectly empty on the other, but every one, nevertheless, assuming a position as truly perpendicular as if adjusted by line and plummet, at the correspondent who was so positive that well-made frames when filled with comb always required bottom guides to keep them in an upright position.

I may now be allowed a retrospective and, I hope, a farewell glance at foul brood. It will be remembered that Mr. F. Smith, late President of the Entomological Society, related at the November meeting of that Association, that when he visited my apiary a short time previously he was witness to the re-discovery of foul brood in one of my hives. This notice has produced so many kind inquiries that I am induced to forestall a communication which I intended deferring until the spring, and describe at once what actually occurred. Having shown Mr. Smith the manner in which my Ligurians continued breeding late in the season I opened a black colony formed of two stocks of driven bees, furnished with a few pieces of comb, which had been stimulated by liberal feeding to recommence breeding and comb-building, but which I felt sure had by this time discontinued breeding altogether. Inspection proved this opinion to be correct, but it also showed half-a-dozen foul cells, the first I had met with in my own apiary since the preceding spring, and this was the extent of the mischief, since a rigid examination of every one of my nineteen remaining stocks demonstrated that all were perfectly healthy. The half-dozen foul cells were at once carefully excised and the stock removed to a distance, where it yet remains, and where I shall be very curious to see if the disease will re-appear in the spring. I myself have a strong impression that it will not, since I think that so trifling an inoculation of the fatal virus (the foul cells themselves having been excised) will, in all probability, have become exhausted during the cessation of breeding usual in the winter season. The only way which occurs to me of accounting for the appearance of this disease in a colony composed of the driven inhabitants of two healthy stocks and furnished only with a few pieces of pure comb is by supposing that the hive (a straw one) into which it had been introduced had not been sufficiently purified from the infection left by its previous tenants. As I find from a letter shown me by my friend Mr. S. Bevan Fox that there is still a disposition to connect the appearance of foul brood with the Ligurians, I may be permitted to point out that in this instance the only hive attacked was a pure black one, whilst the Italians escaped perfectly unscathed.

I have to thank Mr. Lowe for his kind compliance with the request I preferred in 1863, and which has resulted in his favouring us with so valuable and interesting an account of his experience of regicidal attacks among bees. I purpose taking an early opportunity of complying with the wish he has privately expressed, by commenting fully and freely on the facts he has recorded and the inferences he has drawn from them, but I cannot permit a week to pass without expressing my regret at the complete failure of his two Ligurian colonies. Both queens I believed at the time to be as good as my apiary could produce, but although I was then perfectly unaware of it I have now unfortunately too much reason to fear that the bees carried with them the taint of foul brood, and judging from my own experience I cannot divest myself of the idea that this fatal malady may have had much to do with the ill-fortune which has pursued them. I have, of course, already tendered to Mr. Lowe my best assistance in repairing his loss, and I can only hope that this assistance will be as frankly accepted as it is freely offered by—A DEVONSHIRE BEE-KEEPER.

## OUR LETTER BOX.

**POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.**—We are requested to say that Mr. Geyelin finds it impossible to continue answering privately the hundreds of questions put to him from all parts of England in reference to poultry-keeping and egg-preserving, as it entails great expense and labour; and as many questions are identical, and require, in order to be answered satisfactorily, an explanation of the laws of nature which govern certain ascertained facts. Mr. G. will arrange the questions under distinct headings, and give the answers collectively in some of our subsequent Numbers. The difficulty of answering satisfactorily to himself by private correspondence will be apparent by a few we subjoin under the head of preserving eggs only. 1. How can you tell when a jar is air-tight? 2. Can you at any period ascertain whether the jars continue air-tight? 3. Are the eggs not affected by the heat whilst packing? 4. Why should eggs be preserved better in rarified air than by merely packing them in air-tight jars? 5. Does it make any difference in preserving eggs when a few days old? Meanwhile we are happy to state that Mr. G. has just discovered a simple and unfailing mode, not only to make the jars air-tight, but also showing at any time whether they remain fully so, or only partially, full particulars of which we will give in a subsequent Number of our Journal.

**CANKER IN FOWLS** (*Edward Woodcock*).—Scrape out the canker with the nail or a sharp knife and caustic it freely.

**BRADFORD POULTRY SHOW.**—Mr. J. Stevens, of Macclesfield, informs us that the third prize for Spanish Fowls was taken by a pen belonging to himself and not to J. Stephens, Walsall.

**POULTRY SHOWS IN LANCASHIRE.**—Can nothing be done to establish a good poultry show in Lancashire, where we have quite as many, if not more, poultry-breeders than any county in England? We have a show at Manchester certainly, but no one who attended the last could call it a good one. Will nothing rouse the energies of all these inert breeders?—**GAME COCK, Wigan.**

**TO A TIMID EXHIBITOR.**—A word of advice to "A Timid Exhibitor." Go boldly into exhibiting poultry, or, if you keep in that very timid state of mind, you never will be successful. To ease your mind, I will state that I neither breed, exhibit, nor deal in poultry, although I had the honour of representing one of the best yards of poultry in the kingdom, two years back, when I sold all the poultry off that this very timid gentleman seems afraid of.—**JOHN DOUGLAS.**

**POULTRY BOOK** (*H. H.*).—There never was a supplement to "The Poultry-Book." A new edition was commenced by some one, but never completed.

**LA FLÈCHE FOWLS** (*N. B.*).—You will find engravings, together with a full description of them, in Vol. iii., pages 244 and 264, Nos. 65 and 66, New Series.

**AIR-TIGHT JARS FOR PRESERVING EGGS** (*A. B.*).—Apply to Mr. J. Melville, 29, Glaskin Road, South Hackney, London, who is Mr. Geyelin's agent.

**PULLY DYING WITH INTERSINES PROTRUDED** (*L. B.*).—There is no doubt the cause was a difficulty in laying. The bird was, in fact, egg-bound, and, no assistance being at hand, the egg could not be laid without protrusion. The other fowls would eat the egg, under these circumstances, as it would be bloody—a great temptation to them; and they would pick and pull at the protruding membrane, and thereby cause death.

**POULTRY-HOUSE FOR COCHINS** (*W. T.*).—All the Cochins prefer sitting on the ground to roosting on a perch. They always crouch in corners; therefore put your perches in the middle of the house. A house 8 feet square will roost a dozen. Three laying-boxes may face the door. Two perches may be in the middle, sheltered from draught, and let the corners be well filled with dry gravel. If you have spare room, give them more, and put them on the perches after they are at rest. They will take to them.

**FOOD FOR POULTRY** (*Poultry*).—The best food for all fowls is ground oats, mixed with milk. They, however, always want a change. You should sit their eggs at once. Good barley, well scattered in the grass, scraps of bread, scraps of cooked meat from the kitchen—all these are good food.

**WEIGHT OF BRAHMA** (*C. L.*).—We have known a Brahma cock and hen to weigh 27 lbs. That will not easily be found again. A first-rate Brahma cock should weigh 12 lbs., and a good hen 10 lbs. You will see yours is a good one.

**PARROT STAGGERING—HAMBURGH COCK'S COMB FALLING OVER** (*J. L. J.*).—Give your Parrot no hemp seed. Feed on bread and milk, and vegetables, such as carrot, &c., raw. If you can get at fresh fruit, give some. Pear is good; falling that, give apple or orange. Protect it carefully from draught. Give Canary seed moderately. You cannot prevent the comb of your Hamburg from falling over except by tying up with silver wire. That is hardly worth doing, as the fault is a disqualifying one, and we fear you will find it hereditary. Frequent lime-whiting, with thick lime, is the best remedy for flies.

**INSECTS ON CANARIES** (*W. A. O.*).—Your birds are infested with bird lice. If not very numerous Scotch snuff sprinkled on the parts affected, which are generally under the wings and joints, will eradicate them. There is also a powder sold by most chemists, which is very good, called "Dumont's Insecticide Powder," with full directions for its use. Examine your cages constantly, and change them for fresh ones. Wash the old ones well with soap and warm water, and anoint the crevices and doors with rectified spirits of naphtha, and expose them some days in the air. The vermin come out at night from the crevices and irritate the birds; therefore the latter should be changed in the daytime, as they are then more free from the lice. Give the birds a tepid bath occasionally, and then let them out in a room to dry themselves.

**CANARY LOSING ITS FEATHERS** (*H. W.*).—Does the Canary hang in a room in the heat arising from gas burners? or is it over-fat? Either may cause the unnatural moulting. Feed the bird on plain wholesome food, and let it bathe daily. A little flowers of sulphur sprinkled among its seed may be beneficial.—**B. P. B.**

**MILLET** (*H. H. H.*).—The millet used as a bird seed is the seed of *Panicum millaceum*. *Semolina* is not a seed, but a coarse kind of wheat meal made in Russia from the finest kinds of wheat.

**SWARMING *v.* STORIFFING.**—"J. E. B." would greatly oblige Mr. W. W. Cooke, Town Lane House, Denton, near Manchester, if he would favour him with his address.

WEEKLY CALENDAR.

Day of M <sup>th</sup>	Day of Week.	FEBRUARY 21—27, 1865.	Average Temperature near London.			Rain in last 36 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.
			Day.	Night.	Mean.	Days.	m. h.	m. h.	m. h.	m. h.		m. s.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 47.6°, and its night temperature 32.7°. The greatest heat was 62° on the 27th, 1846; and the lowest cold, 18°, on the 24th, 1860. The greatest fall of rain was 0.92 inch.

PEARS ON THE QUINCE STOCK.

LAST year Mr. Rivers kindly gave me twelve Pear trees on the quince stock, and also his "Miniature Fruit Garden," which I found very valuable in aiding me to manage them. The sorts which he sent were—1, Beurré Superfin; 2, Joséphine de Malines (two plants); 3, Doyenné d'Alençon; 4, Beurré Diel; 5, Beurré Hardy; 6, Beurré Defais; 7, Madame Millet; 8, Beurré Beymont; 9, Beurré d'Aremberg; 10, Passe Colmar; 11, Doyenné d'Été; 12, Bergamotte d'Esperen. The above were planted about 2 feet from a south wall, on the 26th of March, and the 9th of April, 1864; and the following is a reliable account of them. 1, 2, 3, were the best, and quite first-rate; 4, was first-rate, but not quite equal to the others; 8 (a great cropper),

and 9, 10, and 11 were all delicious and very good; 5, 6, 7, and 12 either had no blooms or dropped their crop; 7, had an enormous crop, but they were, though covered at night with cloth, frosted at the stem and dropped their fruit. The next lot were in a yard a little in advance of an east-aspect wall—13, Beurré Mauxion; 14, Comte de Lamy; 15, Marie Louise d'Uccle; 16, Duchesse d'Angoulême; 17, Duchesse d'Orléans; 18, Doyenné Gris; 19, Beurré Bachelier.

1, 2, and 3 bore a great crop. All were good Pears; the last was very handsome, delicious, and first-rate; 4, was very large (25 ozs. the three Pears) and handsome, but insipid. In flavour and texture it was the only inferior one. It is probable, that had it been against a south wall it would have been good. 5, dropped its fruit; 6 and 7, had no blooms, or dropped them. I expected to take six fruit per tree. I gathered eighty-two from the thirteen trees.

I should, doubtless, have had more had I not disfruited so largely. I shall in future let Nature disfruit my Pears, as the Pears we leave on, usually the largest, are not the best. They are generally the wormy ones. The trees are nicely furnished with buds for 1865. As examples of abundant blooming I may mention especially, Madame Millet, Doyenné d'Été, Beurré Diel, Beurré d'Aremberg, Beurré Mauxion, Comte de Lamy, Marie Louise d'Uccle, and Beurré Beymont. The last is a fine cropper, very healthy and vigorous, and very delicious. I think it will be placed next year in the first class. These trees, when in flower, put me in mind of Mr. Turner's Modestum Pelargonium. Gentlemen ad-

mired them, and ladies pronounced them "ducks." The "ducks" drank up no end of pump water.

Mr. Rivers wished me this spring to select any of the sorts in his list. I chose another Beurré Superfin, and three that I did not possess—viz., Beurré Giffard, Beurré de Rance, and Thompson's. With this lot he was so good as to send me, with six duplicates of sorts sent last year, the following (making thirty-two trees), of his own selection, hereafter to be reported on. I suppose they are good, for he says, "I will make you as great in Pears as you are in Roses." That may be easily done! The sorts sent were these—Bezi d'Esperen, Beurré d'Amanlis, Louise Bonne of Jersey, Comte de Elandres, Fondante d'Automne, Winter Nelis, Baronne de Mello, Williams's Bon Chrétien, Aglaë Grégoire, Vineuse, Beurré Sterckmans, Prince Albert, Fondante de Mars, Peach Pear, Dr. Trousseau, Glou Morceau, Napoléon, Albertine, St. Michel Archange, Avocat Nelis, and Iris Grégoire. The last three Mr. Rivers says are new, and believed to be good. Thompson's and Beurré de Rance require to be double worked, and were so sent.

I do not send this article to instruct old hands, who have forgotten more than I know, but to encourage others, who, like myself, are young in Pear-growing. To such I say, Buy these, they are, indeed, first-rate—1, 2, 3, 4, and 15, Winter Nelis, Beurré de Rance, and Marie Louise. If more are wanted add 13, 14, 8, 9, 10, 11, and 7, which last, though not yet proven here, is known to be first-rate; 11, is the best early Pear (July).

With regard to Pears on the quince stock, I must make some observations. They require a light soil and cool subsoil. If land is strong it must be made light. They require biennial removal, if the garden is small, not otherwise, renewal of the soil, and root-pruning. They also require to be planted up to but not above the point of union. The soil should not touch the junction of the bud with the stock, or the budded part will root into the soil and destroy the effect of the stock, which should not be. If they are grafted high, earth should be raised like a mole-hill to the point of union. They require pinching rather than pruning. I keep mine like shrubby Calceolarias, with their shoots pinched to three leaves in July. If large pyramids are required, the leader, of course, must be allowed to go up. If the pyramids are too large to be removed biennially, they may be root-pruned *in loco*, in a radius of 18 or 36 inches, according to the bulk and height of the tree. Root-pruning is not sufficiently practised.

Young Peach trees would come into bearing sooner if they were cut less at their heads and more at their roots. People plant and treat things wrongly, and then cry out lustily, "It is all humbug." They bury rather than plant trees, and "stick and dab" them in; but Nature never was a sexton or a bricklayer. Both are wrong; the first, because the roots are too far removed from the action of the sun and atmosphere; the last, because the roots cannot run in concrete. Nature casts her seeds on the ground, hence the trees have abundant surface roots. It is better to plant shallow, and mulch and water in burning

summers, than to bury the plant to obviate burning and to save watering. The tap roots may produce wood, oftentimes too strong; but radial roots produce and bring to perfection fruits and flowers.

Let Pears on the quince stock be propagated low, for they must be earthed-up to the point of union. Remember the following maxims:—"Nature never was a sexton or a brick-layer." "Nature loves sun and water in the same ratio." "What you take out of the ground you must replace, unless the ground is redundantly stored." "It is better to follow and assist Nature, than to thwart and retard her."—W. F. RADCLIFFE, *Tarrant Rushton, Blandford.*

## THE MODERN PEACH-PRUNER.

No. 4.

### SOILS AND MANURES.

THE particular kinds of soil which are adapted for Peach-culture must now be considered. A more important consideration cannot well occupy the attention of the growers of all stone fruit. The subject is a large and difficult one, and is far from well understood. It is not pretended, therefore, to give more than an outline of certain established truths, which, it is hoped, will induce cultivators to examine more carefully the nature of the soil composing their gardens, so as in some measure to secure materials now known to be indispensable in Peach-culture.

There are three principal earths which enter, more or less largely, into the composition of all soils; these are clay, siliceous, and lime. Soils are made by a complex combination of materials obtained from these three primitive earths. These materials vary considerably in their proportions, and so affect the general nature of the soil, which, moreover, depends very much on the quality of the subsoil. For example: a chalky subsoil gives a whitish appearance to the surface soil; when red sandstone constitutes the subsoil the earth above it has a reddish hue; on gravel it has a yellow tinge, and on blue clay it appears greyish.

Clay is a constituent of all good soils; in fertile ones there may be 15 per cent.; but in those which are barren 40 per cent. Its absence makes a soil too dry, while too much of it constitutes a soil retentive of moisture, and apt to harden and crack with heat. The rays of the sun cannot penetrate stiff clays. The red clay soils are the hardest, and the black clay the most plastic. The purest clay contains at least 60 per cent. of sand, and is always mixed with mineral and other substances. Clay soils, properly treated, are among the very best for stone fruit. The first consideration is to drain them thoroughly of superabundant water, which would otherwise result in soft, spongy wood, and moss on the trees. The next thing is to incorporate with them all such materials as will render them permeable by the air. This should be done to the depth of at least 2 feet, by means of steel forks, using for this purpose such materials as sand, coal ashes, gravel, lime from very old buildings (of this a large proportion), broken pottery, pounded oyster-shells, &c.; in fact, anything to keep the soil open. The general border-drainage of such soils should be itself 12 or more inches in depth, according to the quality of the clay. Drainage withdraws the water from the roots, and allows the air and sun's heat to reach them and supply that warmth which is absolutely required for carrying on their functions.

A main drain, at least 4 feet deep, running under the walks, and connected with this border at intervals, is requisite, unless in the case of stony subsoils. It is hardly known how much drainage, well carried out, increases the temperature of the borders. Whatever tends to increase the temperature of the soil in naturally cold and damp countries is of the highest importance. Continental writers are not so explicit on this point, but possibly the amount of evaporation lessens the danger. Of late years this subject has gained ground even among them.

Siliceous, or sand, is found more or less in all soils. Sands vary much in colour. Sand more unequally reduced forms gravel; when flinty, it is termed siliceous; with mica, micaceous; when very fine, dust. Silica allows water to evaporate from it twice as fast as chalk, and three times as fast as clay. Sandy soils are curly, and wrought easily, but are incapable of great production. They are "hungry

soils," and in them manures soon disappear: these should, therefore, be applied only for the crop of the current year. Siliceous soils vary in colour from white to red, according to the quantity of oxide of iron which they contain. They are friable and penetrable to a great extent by the air, but liable to dry up. There are, however, exceptions to this general rule. In some parts of the eastern counties of England there are large tracts of land composed of calcareous sand. These soils are apt to become binding rather than dry on the surface, and as such they are more fertile than loosely-constituted siliceous soils. Usually loose sandy districts are very unfertile when planted with fruit trees, especially Peach trees. Such soils should be mixed largely with stiff alluvial loam, and have rich surface dressings and mulchings in times of drought. Soils thus treated are much improved, but whilst the Peach grows fairly in them the fruits, though of good flavour, are not large. In order to supply carbonate of lime freely, powdered lime rubbish and gravel mixed (so as to separate the particles), the whole spread over the surface, would gradually find its way by the infiltration of water all through the soil. Thus only could a siliceous earth, rendered firm by clay with lime added, be called a fair Peach soil. Pure silex is extremely barren. When, however, it appears of a reddish colour it indicates the presence of oxide of iron, which combines readily with the oxygen of the atmosphere and retains it. These ferruginous soils are excellent. When silex is in too great a quantity there is an abundance of blossom, but the fruits are not so large as in other cases. The leaves of the trees are also more liable to curl and the attacks of aphides.

The third chief earth found in soils is lime. The value of lime in the culture of the Peach, the Vine, and indeed of all fruit trees, has not yet been fairly estimated. Lime appears in soils in the form of carbonate of lime, or chalk. Without the admixture of other substances essentially chalky soils are very unfertile. A chalky subsoil is unfavourable to fruit culture. Calcareous soils absorb moisture, and dry up with equal rapidity. Calcareous matter is, however, of the highest necessity in Peach-culture. Its absence is at once perceived by the falling of the fruit at the period of stoning, because carbonate of lime constitutes a considerable portion of the stone. Sand and clay are the appropriate ingredients to mix with chalky soils, so as to render them more firm, yet permeable and fertile. Clay destroys the whiteness of the chalk, which is unfavourable to the due absorption of the sun's rays. An incident strongly corroborative of what has been advanced respecting the value of lime, occurred lately at Sawbridgeworth. The soil of that nursery is very largely mixed up with comminuted chalk; the water is therefore impregnated largely with carbonate of lime, and its effects on Peach trees and Vines in pots have this year been remarkable. The trees and Vines were copiously watered, and a thick deposit of lime was found adhering to the drainage. The roots were finely developed, while vigorous and healthy growth was visible everywhere. Other experiments have fully established the value of lime.

The border for Peach trees should always have a good slope. Its width, for walls 10 feet high, should be about 5 feet, provided this space is never encroached on. A rich calcareous loam, of an unctuous texture, soft to the touch, made pervious to air and heat, is a favourable soil for the Peach. Manures should be gradually forked in, but the roots should be so near the surface that forking 3 inches deep would be dangerous. These Peach-borders should not be further disturbed save for weeding. Although thus near the surface, roots can be readily protected from the effects of evaporation during the summer by mulchings of litter, and, in the same way, from excessive cold.

Calcareous matter (old lime rubbish, powdered oyster-shells, and broken bones), should be added to the extent of one-sixth of the soil. Manures composed of well-rotted vegetable refuse, intermixed with stable-droppings, allowed to stand for some time before using, and well turned fortnightly, with lime and soot intermixed, are excellent. Summer mulching should not be applied till the earth has been well warmed by the sun. Charred earth soaked in manure water is highly stimulating, but should be carefully used.

Although the list of manures is long, many Peach-growers are of opinion that such as are of slow decomposition, as old woollen materials, are the best; at any rate, vegetable manures are of much value, and are too often neglected.

These, when applied, should not be buried too deep, otherwise fermentation is hindered. Wood ashes offer much that is valuable. The ashes of all vegetable substances contain lime, phosphoric acid, and alkaline salts. There is usually a little charcoal or carbon left which is most valuable. These ashes should be applied when newly burned. The effects of manures, however, much depend on the quality of the soil to which they are applied, and on its state at the time of application. Manures should be thoroughly incorporated with the soil.

In the case of orchard-houses a well-drained locality is absolutely indispensable. Many failures occur from neglecting to examine into the nature of the subsoil on which the building is to stand. Mr. Rivers has so often insisted on this point that it is surprising it is not better understood. Any situation almost is preferable to a cold ill-drained one. It must be evident that no Peach-blossoms can set in such houses, shut up as they may also happen to be at that season. The manures required for orchard-house trees are naturally of rather a more stimulating character than for trees in the open air. Thus, rich surface-dressings often renewed are required. Liquid manures and weak guano water, alternately each week in the summer season, are beneficial applications. This chapter, then, can only be considered as suggestive, and as such only is it offered.—T. C. BRÉHAUT, *Richmond House, Guernsey.*

## ROYAL HORTICULTURAL SOCIETY.

### ANNUAL MEETING.

The Annual General Meeting of the Fellows of the Royal Horticultural Society was held on Tuesday, February 14th, at South Kensington. Lord Henry Gordon Lennox, M.P., presided. The attendance was not large.

The minutes of the last meeting of the Council were first read by the ex-Assistant Secretary (Mr. Murray), and confirmed.

Mr. Edmonds and Mr. Fortune were next appointed scrutineers to examine the voting-papers for the election of the Council and officers for the ensuing year.

Mr. A. WESTON moved that the resignation which Mr. S. H. Godson had sent in to the President (the Duke of Buccleuch), of his seat at the Council-table be not accepted.

MAJOR PHIBBS seconded the motion.

Mr. THRING desired an explanation from Mr. Godson of his reasons for resigning.

Mr. GODSON replied that he explained his reasons in the letter conveying his resignation to the President—namely, that he had been refused an examination of the accounts of the Society, in consequence of which he felt that he could no longer sit upon the Council with satisfaction to himself, or with justice to the interests of the Society. It had been alleged that the particular account he wished to see was a private account; but how stood the matter? He said in his letter that a statement was made before the Council by which a balance was shown to be against the Society, and it was not satisfactory. He accordingly proposed that a sum of £1000 should be taken up on loan from the bank until the accounts were investigated by the Council, and that a satisfactory account be given by the next meeting; and the consequence was that that sum of £1000 was borrowed, and the matter stood for the next meeting. At the next meeting an account was produced, stating that £6772 or thereabouts of the life compositions, which had been simply held up to that time as a guarantee, should be realised. At the same meeting it was ordered that £3000 or £4000 of that money should be applied to the general purposes of the Society; and therefore he the next morning called at the offices of the Society, and asked Mr. Murray for a sight of the accounts; but Mr. Murray declined to afford him the sight, and accordingly he brought the matter under the notice of the Council at their next meeting: It was, however, answered by Mr. Murray and Mr. Cole that Mr. Murray had no authority to produce the account, as it was a private matter of Mr. Cole's. The Treasurer was the person to produce the statement of accounts, but he refused. He said, "You are the opposition." He (Mr. Godson) answered, "Well, I can't help that;" and upon reflection he thought that if an inspection of the accounts was to be

refused to a member of the Council he could not retain his position. Therefore, he wrote to the President of the Society, sending in his resignation; and he had received in reply a very handsome letter, wherein his Grace said he regretted the Council would lose the benefit of his services, but still more that there should be anything to induce him to withdraw from it. He (Mr. Godson) having resigned, could not of course attend any more meetings of the Council; but came up at the last meeting, and told the gentlemen present that it was monstrous to expect any one to concur in the sanction of the accounts, which the Council necessarily had to do, unless they were free to examine them at any time [hear, hear]. It was extremely unpleasant to be at variance with either the members of the Council or any of their officers on any point, but much more upon a matter of this kind. Everything he had stated had been verified by the accounts to be placed before the meeting that day. Not only was what he had stated verified, but matters were much worse than he had represented them, thus proving that he did not resign his position at the Board without sufficient grounds. He could only say, seeing that a motion was before the meeting to retain his services on the Board, that if he went in armed with the support of the meeting, his position would be very different, and very much more dignified and pleasant than what it had been. If it was their pleasure that he should continue to act on the Board, of course he should feel it his duty to comply, and, moreover, he should feel it his bounden duty to watch closely their interests.

Mr. THRING said Mr. Godson had not answered his question, whether or not he resigned willingly; for he (Mr. Thring) did not think this was the way for Mr. Godson or any other gentleman in the Council to treat the Society. If Mr. Godson felt himself aggrieved it was not his duty surely to resign, still less to come there and attempt to force an expression of approval of the course which he had pursued. No one regretted more than he (Mr. Thring) did losing the services of Mr. Godson, for he really believed that he attended most carefully to the interests of the Society, and was a most valuable member of the Council; but, on the other hand, when a gentleman chose to resign his seat at the Board because he was not satisfied with the proceedings of that Council, he (Mr. Thring) said that was not a proper mode of dealing with the Council or with the Society, for the business of any society carried on in that way could not possibly redound to prosperity or harmony. Look at the clubs of London, how were their members to hope to get on with a man who on the slightest pretext chose to send in his resignation, trusting to the members to throw it back? If a man in a club was beaten by a majority, it was surely not the right course to pursue to retire. If his conviction remained unshaken, though beaten by a majority, it was his duty to remain, and try with the assistance of time and reason to convince others. If he was persuaded there was something wrong, it was his duty to remain and endeavour to put it right. If he suspected fraud, he should certainly not retire and leave the fraudulent to go on perpetrating their nefarious practices, but should rather persevere in his efforts to expose the fraud, and in the event of succeeding then to propose that the delinquents be turned out by a vote of censure or otherwise. He (Mr. Thring) never yet belonged to a society in which a member threw up his connection at the very moment he was wanted, and came saying, "Give me the *éclat*, the glory, and force me back on the Council." That was what Mr. Godson had done, and he (Mr. Thring) thought he had committed an error of judgment. He therefore asked the meeting to accept Mr. Godson's resignation.

Mr. CLUTTON observed that as he had been referred to by Mr. Godson it was necessary for him to say a few words on this matter. Sir Daniel Cooper was the Treasurer, but as he had gone to Australia, the Council did him (Mr. Clutton) the honour of placing him in Sir D. Cooper's position. As an ordinary member he held, and as a member of the Council he had always held, that every member of the Council was just as responsible as the Treasurer for the correctness of the accounts. He had just as much right as the Treasurer to come and look at the accounts; he (Mr. Clutton) went further and said, it was his duty to do so. The Treasurer was merely the custodian of the money, paying cheques, or otherwise, according to the orders of the Council. The bye-

laws, indeed, specified that he could not make any payments whatever, save the salaries, excepting by the orders of the Council. If, therefore, Mr. Godson thought it his duty to withdraw himself from the examination of the accounts, with which he was very familiar, he (Mr. Clutton) must say it was entirely his own act. At a certain meeting, no doubt, a paper was produced, but it was a mere private paper of Mr. Cole's. He (Mr. Clutton) was at that meeting, and he simply looked at the paper, but not as a paper coming from the Treasurer; for it did not do so at all, it was a mere estimate of what was likely to be the result of the year's transactions. The accounts were not then made up, and it was some months before they were due. As to Mr. Godson's being refused a view of the accounts, nothing of the sort took place, because they were as much open to Mr. Godson as to himself or any other member of the Council: therefore, he said, Mr. Godson was wrong in withdrawing from the Council on that ground.

Mr. COLE: Mr. Godson mentions my name under some kind of hallucination on the subject. It is quite true I ventured to make an estimate on my own responsibility as an individual member of the Council. I am not careful of my papers; I leave them about, and on this occasion, it appears, I did so. I was so indifferent to the matter that had Mr. Godson asked to see the paper, although it was my own private memorandum, I should have had no hesitation in complying with his request. It was left on the table, and that day or next day Mr. Godson, it seems, expressed a wish to have a copy of it. I was not consulted in the matter; I did not even know that he had made any such application, otherwise I should have at once said, "By all means have it; get all the good you can out of it." But Mr. Murray felt himself warranted in refusing a copy: consequently the Fellows of the Society will see that it is not quite correct for any gentleman to say he was refused a sight of the accounts. I do not recollect precisely what this was; it may have been an estimate, and a very wrong one; but as to my having any objection, I had not the slightest, nor have I at this moment. However, it had really nothing to do with the accounts. The accounts are all open to Mr. Godson, who takes a great interest in them.

The CHAIRMAN put the motion and amendment to the meeting. For the former there were only 10 hands held up; for the latter 21. Mr. Godson's resignation was, therefore, accepted.

The SECRETARY then read the Report of the Council for the past year, and a printed copy of the accounts having been distributed to the members, they were taken as read.

A Member then begged to move the adoption of the Report, which, he said, proved that the science of horticulture was not neglected by the Council, whilst the comfort of the visitors to the gardens had their anxious attention. It was a very gratifying Report, and in no feature more so than in that where it was stated, that arrangements were being made with the Society of Arts for adding an examination in gardening to the examinations which they conduct throughout the United Kingdom, with the view of improving the education of gardeners. There were great facilities connected with this Society for effecting such an object, and it was very well known that the old Chiswick Gardens were a very good school for gardeners. He then made some remarks on the arcades provided in the Kensington Garden, and on behalf of the ladies thanked the Council for providing them. Some of them, he had noticed, were glazed at the back, and filled with plants, which added very much to their picturesque effect. He, therefore, hoped to see this principle carried out to a greater extent.

Major-General Sir A. SCOTT WAUGH seconded the motion.

Mr. A. F. GODSON rose to move an amendment:—"That a Committee, to consist of five members with power to add to their number, be appointed to investigate the affairs of the Royal Horticultural Society, and to report at the earliest opportunity—1, What is the true financial state of the Society; and what are the circumstances under which the hitherto enormous expenditure has been incurred? 2, What measures should be adopted to save, if possible, the Society from impending insolvency? And that for these purposes the balance-sheet of 1864-5 be referred to such Committee." Mr. A. F. Godson said he did not attempt to urge one word against the Report, but simply with regard to the

accounts, therefore it was useless for him to say anything in reference to it: besides, no one had seen the Report, and therefore no one could be expected to make much remark upon it. With regard, however, to the accounts he had to say a great deal. First of all he wished to draw attention to the balance of 1863, £1433 5s. 5d., and to the liabilities of 1863, paid off £933. Now they had allowed £500 for sculpture, which became due in 1863, and remained over to this year. They would find that £500 was taken credit for as against 1863. That might be the way of doing business in this Society, but it was not the usual way. With regard to the second item, £424, on the transfer of life compositions, he compared the course taken by the Council with the fable of killing the goose that laid golden eggs. The life composition fund, producing £400 a-year, had been killed, and therefore they would never see that again. The £8260, receipts for admissions and subscriptions, in 1862 amounted to £8600, and last year were £8400. The annual subscriptions were now £7300, whereas in 1863 they amounted to £7700. There had been a loss of £900 on the exhibitions, while the Royal Botanic Society had cleared £2000 by their shows. He also drew attention to £5 18s. for odours and perfumes of flowers, and asserted that the maintenance of the Society cost £40 a-day, which he considered altogether unwarrantable. The Journal of the Society cost £300, and yet he looked upon it as completely valueless—as rubbish in fact, for all it contained was correspondence and preliminary puffs. The Arboricultural and Floral Committees had cost in one year (1862), £300, but instead of assisting horticulture the Council did the reverse. With regard to the handbook, against which there was a liability of £50, he wished to know who had ever seen it. A few dozens, he believed, had been printed, but they were of no earthly use; and he must really ask whether they were to go on throwing away £50 here and there upon things which were utterly worthless. The *conversazione*, over which something like £330 was spent, had been the laughing-stock of everybody. He wanted to know what it had to do with horticulture. Certainly it afforded an opportunity to a number of nobodies to turn out very grand and show as if they were somebody and something. Last year, he drew attention to the word "rent" not being named in the accounts, when there was £2300 due to the Commissioners of 1851 under that head, and there was now £4700 due. The word "rent" was now inserted, and although when he complained of the word not being there, he was told no rent was paid, he was told now that it only amounted to the magnificent sum of 4s., yet there was £800 put down for rent, rates, and taxes in respect to Kensington alone. With regard to the payment of interest on debentures, the Charter stated that, first of all, the expenses of the gardens should be paid, then the interest on debentures, after that the debt due to the Commissioners. Now, he begged to tell them, that had the expenses of the gardens been paid, not a single farthing would have been available for the debentures, much less the liquidator of the Commissioners' debt. But that would not do: the Council actually violated the Charter by paying the interest on debentures before the cost of maintaining the gardens. What chance, he should like to know, had the debenture-holders of getting anything next year? Coming to the revenue, the whole amount realised was about £14,000; but £20,000 had to be expended. He was a young man and had a great deal to learn, but he imagined that that was not the right road to prosperity. Last year £17,400 was spent, but they managed to meet it, which was very far from the case this year. He had drawn attention on a previous occasion to the manner of keeping the accounts, the heading, "liabilities and assets," having been omitted, and he was told that they should be better kept, but he saw no improvement. The bye-laws said that a true account of the state of the Society shall be rendered at the Annual Meeting, but this was not a true account. In the year 1861, there was an account of the assets and liabilities, which showed clearly what they owed. That was changed next year to profit and loss account, but last year there being a great deficit it was left out, and this year the state of things was worse; so it would not do to put it in. There was a balance in 1861, according to the accounts, of £10,000 in their favour. Now, however, what with rent and £3546 liabilities this year and other things, £20,000 had disappeared in four years. The

waste was accounted for by such things as those garden improvements which had cost £2500 this year, and which were no improvements at all; they, perhaps, might have been had they been done at the Brompton Cemetery. Now he came to a matter which really was shameful. He became a life-composition member on the guarantee of what he imagined was an honest and honourable Society; but now he had nothing to look back to, for, owing to the bankrupt state of the Society, subscribers would withdraw. The debenture-holders, too, had very small prospect indeed; and all he could say was, that it was utterly hopeless for them ever to expect anything unless a committee of investigation was granted. It was a gross breach of the Charter taking the money of the life-compositions for bear's grease shows and to build up a number of rubbishy things which were no better than skittle-alleys and bowling-greens. There was such an overwhelming majority for the South Kensington Museum on the Council that he could not hope for any redress in behalf of horticulture. But whether he obtained his point or not he cared not; he should endeavour to put the Society in a straightforward course. Now he would say one word with regard to the future. They would this year have to start with a deficit of £4000, and the income would most probably be less than it had been last year. Of course, the Council considered they had a brilliant prospect for the future; indeed he never knew when they had not a brilliant prospect, but they had never yet realised it. Suppose they had an income of £13,000, out of that they owed £3000, leaving them £10,000. The necessary outgoings, independent of the rent, would amount to £5000; thus £5000 was left to defray the expenditure, which expenditure in 1863 was £19,000, and last year £20,000. Deducting the outgoings of which he had spoken, there was £15,000 left without a farthing to meet the deficiency.

Mr. A. WESTON.—Without agreeing in every respect with what has been said, may I be permitted, before seconding the resolution, to give my opinion on some points, which opinion is shared by a considerable body, if not by a large majority, of the Fellows of this Society? Setting aside the eligibility of the site for horticultural purposes, I would call your attention to the position of the gardens, and to the fact that at the present time (except upon sufferance), we have but one access to them—the two side entrances being the property of the Commissioners of the Exhibition of 1851, who can at any time take possession of them for building or other purposes by giving three or six months' notice to that effect. I do not presume to offer an opinion as to the management of the gardens, but cannot conceive how the science of horticulture can be promoted by the exhibition of soap and scents in the conservatory, or the performance of Mumbo Jumbo in the arcades. Such sights are more worthy of the Crystal Palace and Cremorne; and we have already lost the services of more than one able professor, who felt that they could not conscientiously approve of the Horticultural Society being made subservient to other interests. I shall say little of finance. I believe we are very considerably in debt, and the number of Fellows is decreasing. Under these circumstances I think the Council were hardly justified in giving £1800 for the great unsightly tent whose bare poles are now such an eyesore to the neighbourhood. The greatest calamity that has happened to the Horticultural Society has been its amalgamation with, or rather its absorption by, another body. Public opinion has spoken loudly through the press on these subjects; but nothing can be done till we free ourselves from the influence of the small knot of individuals, the self-styled patrons of the arts and sciences, who are sacrificing our property and destroying our Society.

Mr. COLE rose to reply. I shall confine myself, he said, to the correction of a few mistakes Mr. Godson has fallen into. He commenced by upbraiding us with carrying over £500 for sculpture, which is still a debt. Now the sculptor (Mr. —) had a commission—he has not executed it, and therefore has not been paid. Mr. Godson, in commenting on the accounts, said that the daily admissions had fallen off. Now I find that the daily admissions for the year 1863, as distinguished from the exhibition receipts, were £134; this year, excluding the Rhododendron Show which is put amongst them, they amount to nearly £700. We had the misfortune last year of not receiving so much as we usually

did for exhibitions. Two of the days, as will be in the recollection of members, were extremely unfavourable as regards the weather, and such as to deter the public from coming out. That was a piece of ill luck which was the great cause of the decline of the exhibitions at Chiswick; and I am afraid this dependence upon the weather is one which can hardly be cured, except by the course the Council has taken—that is, of having places under cover. We have now provided places under cover of various temperatures, where plants are well exhibited, and to a great extent we are independent now of the elements. We were not, however, last year provided in this respect to the same extent as now. And then Mr. Godson coupled his observation by an extremely courteous remark, or, rather, I should say, a comparison between ourselves and another society. He asserted, to my great astonishment, that whilst we had lost, that Society had gained £2000. I am afraid this is one of his usual dreams. If he will consult the accounts of that Society he will see they have had apparently a surplus of £900; but they have never charged themselves, and never do until the following year, with the extra expenses of those exhibitions. Therefore it is impossible to say at this moment whether the exhibitions of that Society were or were not paying; but we have the published fact that in the previous year they lost £500. Then Mr. Godson flies into this curious mistake: he goes into an estimate of what he calls a loss on the perfume exhibition, and he estimates that we lost £10 daily, and our working expenses are £10 daily. That is one of those odd mistakes people will fall into. It is certainly quite true that these Gardens cost £3000 a-year to keep them in order, and you may, if you like, say it costs us £10 a-day. The working expenses of the Gardens upon ordinary occasions go on whether or not. You must have your door-keepers, your superintendent, your man at the engine, and so on; but Mr. Godson does not seem to be aware, whether we take 1s. or £100 a-day, the expenses must go on. As to his remarks about the Journal, it is a matter of taste whether or not it conveys information. Then he tells us that we are spending £20,000 a-year, and next year shall have only £5000 to meet it. Now he has made a mis-statement of the expenditure of last year. The current working expenses of last year were less than the year before; nevertheless our outlay last year was very large, as is well known to the members of the Society. They will recollect that at the last annual meeting it was stated that the Commissioners of 1851 would make an outlay of £13,000 to carry out certain works in the Gardens. The Fellows agreed to spend £5000, and we spent £3000, and we made some further outlays, but these are outlays, not current expenses but all capital. The hon. member then twits the Council by saying we have spent the life subscriptions. Well, it is a matter within the discretion of the Council; it is a matter of the Charter whether or not it is not most to the interest of the Society to have the life subscriptions in the bank paying £4 per cent, or expended in improvements on the Gardens. I hold in my hand a paper which refers to the time when that gentleman was very rampant in the Society—the annual Report of 1860, the pith of which is this—that at that time, as bearing on the Kensington interest, there was a debt on Chiswick Gardens amounting to more than £10,000, which somehow or other was wiped off by the subscriptions to the South Kensington Gardens [No, no]. Then, I suppose, the gentleman paid it out of his own pocket. I find it here [Reads the passage]. They had a Report in 1859, and they had an income which, though reviving, still was inadequate for the year, which had increased within the year £600. The debt bearing no interest, beginning in 1859, amounted to £8000, which, exclusive of a contract debt of £2700, had become urgent. Now, the state of matters in 1859, before South Kensington was heard of, was that the Society was £10,000 in debt, and this was paid off. But how paid off? I say by the subscriptions of gentlemen who have been kind enough to join South Kensington [No, no]. I should like to have it shown that it was paid off in any other way. I have yet to learn that Mr. Godson paid it off, and I take it for granted that by a very simple process it was paid off. Then he goes on to say, this is not a true account, which, of course, is not a very high compliment to the Auditors who have certified to the accounts. "Honest" was another word he made use of; but

whether true or honest the Auditors, who are respectable gentlemen, had certified that they were true accounts. It is altogether misleading the Society to say our income is only £5000 and our outgoings £15,000. It is no such thing. If you look at the present mode of working the Society, the expenses are between £12,000 and £13,000 a-year. The income last year, putting aside other things, was very close upon that sum. Hopes are entertained that our exhibitions may improve a little, and while the expenditure is put down at £13,000 or £14,000 the income is calculated to amount to the same sum. This gentleman, I have no doubt, is a great debenture-holder, and thinks it will give that body some encouragement to be always telling them they are in great jeopardy; but his statement is wholly fallacious on that point. Of course the debenture-holders know the property of the Society, and the loss upon the property, upon these grounds down here; and therefore I say, it is a misrepresentation to endeavour to alarm the debenture-holders by telling them their interests are in jeopardy. I think my observations have answered that gentleman (Mr. Weston), who read us his observations. He thinks great mischief will result from our connecting the Kensington Gardens with the Commissioners of 1851. I have already shown you the Kensington interest has paid off the Chiswick debt [No, no]. I maintain that is the fact. I have shown you were in debt. The facts are these, as stated in the Report, that you never had Chiswick in so productive and well-managed a condition as at this moment. I challenge anybody to say that within their recollections of Chiswick, Chiswick was ever so productive to the interests of horticulture or of seeds for the members as at this moment. If I am wrong I can be proved to be wrong. The figures show the value distributed over the various members. You will recollect that in 1859 a Committee was formed, of which I daresay Mr. Godson was a member, in order to sell off Chiswick, but the result of the establishment of this unfortunate Kensington has been that Chiswick has been saved, and not only saved, but put into a better position. As for the gardens here, Mr. Godson alluded to them as fit for a cemetery. They may look as a cemetery, but it is possible he may not be so clear in his vision as other people. But even if they have the appearance of a cemetery, they recommend themselves to the public, as is abundantly proved by the members increasing their subscriptions—perhaps with a view of being buried there. There is the fact, that the members are increasing, and that the number of persons frequenting the Chiswick gardens are increasing every year four times what they were before the Kensington interest went into partnership with Chiswick. I therefore demur altogether to the motion brought forward by Mr. Godson, and hope the members will give it a decided negative.

Mr. CLUTTON.—In looking to the capital account, I find that these gardens were originally formed by means of life members. I find that the life-members' subscriptions amounted to £17,000 originally, of which the greater part was invested in the formation of these gardens. It is quite true that last year we had a considerable sum invested in debentures, of which we have about £2000 now invested. The remainder has been spent, as the former sum of £17,000 was spent, in the formation of these gardens. It was scarcely possible when these were first formed, as everybody knows who has to create a garden, at once to do all that was necessary. In fact, you cannot get trees to grow, you cannot plant a garden all at once, and erect arcades and buildings, and, therefore, it was thought by the present Council that now was the time when the gardens required additional improvement and expenditure, and upon that recommendation they have invested a considerable portion of these life compositions. There is nothing in the Charter or bye-laws to prevent the expenditure of these life compositions. A similar thing has been done in the Botanic Society; therefore, I am not aware that anything improper or inconsistent has been done in including these life compositions in our accounts. They have been spent, as all former capital has been spent, in the improvement of these gardens, and not in ordinary expenditure. Mr. Clutton then went on to say, that the holding of exhibitions on Saturdays might be the secret of the Botanic Society's success. In this Society there was a great objection to Saturday. He confessed that the accounts might be remodelled with advantage, and he ex-

pressed a hope that that would be effected, but those presented were at the same time perfectly correct.

Mr. W. WILSON SAUNDERS said the Commissioners of 1851 had met this Society in the most friendly way possible. Whenever they wanted money, or in any way to improve their property, the Commissioners had manifested a liberality which he had never before known in landlords. The Commissioners not only displayed a most kindly spirit towards this Society, but evidently were actuated by the sincerest sympathies in the science of horticulture.

Mr. THRING said he was a Commissioner of 1851, and a debenture-holder and subscriber in this Society. At the same time he was perfectly independent of the Council, on which he never sat, but he fully approved of their proceedings. They were told by Mr. Weston that the Commissioners absorbed the Horticultural Society. It was absolute twaddle. It was, perhaps, unfortunate that the Commissioners had entered into partnership with this Society; it was certainly very unprofitable. They had done everything to assist the Society; the other day, only, they granted them £13,000. Still, if it were not for this constant "nagging," this discontent, they would get on very well together. If the gentlemen who ought to support the Society, however, found fault with everything, and accused the Council with dishonesty and of a want of truth, they could not go on—no society could go on under such circumstances; and he trusted, therefore, this meeting would give the most emphatic negative to Mr. Godson's motion, which was, in fact, a vote of censure on the Council; and if it was a vote of censure, it would be very much more manly on the part of those who supported it to say so—to say that their intention was to turn out the Council. As he said before, all of them who belonged to a club knew there was nothing so injurious as constant squabbling, constant quarrelling, and attempts to upset the authorities. He had no interest whatever in the matter, but he did advise the Society, as he had advised—may, implored—other societies when disturbed by similar motions, to refuse to entertain any such motion—to refuse to pass a vote of censure unless there was a charge of absolute fraud made out against those who were put in power. What did Mr. Godson propose to do? To appoint five gentlemen who should examine the accounts from the beginning of the world to the present day? Really, were they going to be fools enough to sanction any such proceeding? and if, as Mr. Godson stated, they were in a state of insolvency, were they going to be fools enough to publish the fact to the world? There was never anything so monstrous. When the Commissioners first took to the Society, it undoubtedly was in a bankrupt state; but now, by whatever means—whether through the assistance of the Commissioners or not—it was flourishing—it was doing much better than it had done—it had excellent gardens, and afforded a considerable amount of gratification to the public, let alone the eminent services it rendered to horticulture. Mr. Godson had put his motion in an obnoxious form, and, in speaking upon it, had made use of terms which ought never to have been addressed to a society such as this.

Mr. WESTON remarked that he distinctly stated, on rising to second Mr. Godson's motion, that he did not agree with many of his observations. He had not the slightest intention of imputing fraud against any one; on the contrary, he believed the Council had faithfully performed their duty. He repeated that he did think the Horticultural Society did wrong in connecting itself with the Exhibition of 1851. The Commissioners had certainly done their duty in trying to prop up the concern; at the same time he did not think the interests of horticulture were benefited by such assistance. He considered the gardens were not in the right place for horticulture; they ought to have confined themselves to Chiswick, which was in a much more favourable position for the purpose. He did not know the name of the gentleman who had just spoken (Mr. Thring), but he had spoken rather too warmly on the subject.

Mr. JAMES BATEMAN was glad Mr. Weston had taken the opportunity of disclaiming any sympathy with the remarks of Mr. Godson, to which he (Mr. Bateman) had listened with very great pain. He was not prepared to dispute their accuracy in every respect, but the animus of opposition to the Society and the Council, which seemed to dictate the remarks, was painful to observe. Now, Chiswick was

almost in a state of bankruptcy when the connection was formed with the Commissioners, and by this time they would have been in the *Gazette*, but for the assistance they got from the Commissioners. Regarding the situation of Chiswick, he could speak from experience. For thirty or forty years he had been connected with Chiswick, and he must say that some of his happiest days had been spent within its walls. Consequently, his feelings were entirely in favour of Chiswick. At the same time they could not shut their eyes to the change which was taking place in the aspect of horticulture in England, and in this metropolis in particular. He remembered the first show held at Chiswick. It was a poor affair, but still it was a beginning. He saw gradually the interest increase in those shows until the flood-tide of prosperity set in and poured along until they came to form a very large, not to say the largest portion of the income of the Horticultural Society. He then with much eloquence explained four points, in which he said, Chiswick was eminently useful in former days—first, as an experimental garden, in which were gathered together a large collection of varieties of fruits, to which constant additions were made as fresh varieties were introduced; second, as a nucleus for the introduction and dissemination of rare plants, which he believed gave Chiswick its prestige in the first instance; third, as a garden where especially hardy plants might be seen in the greatest perfection; fourth, as the theatre of great shows. He looked upon it that with a few exceptions the whole of the known regions of the world, where specimens of horticulture could be found had been explored; consequently, he argued that there was not that necessity for an establishment like Chiswick, which there was before those regions had been visited. There might not be as many eminent horticulturists on the Council as was desirable, or as there were in former days, but it was not from any disinclination on the part of the powers that be, but rather a diminished supply of these worthies. Never was there a time when there were so few eminent and practical men in the horticultural world as at the present day.

Mr. EDGAR BOWRING (Secretary to the Commissioners of 1851), said he was glad to hear that the accounts were intended to be simplified, because in their present state they were difficult to understand. It was a great fallacy on the part of Mr. Godson to say that their expenditure was £20,000 a-year, and that they had only £5000 to meet it. It was very true the accounts showed a balance on the wrong side; £20,000 expended, and only £13,000 or £14,000 received. On the face of the accounts that might appear to be the case. If the Commissioners treated their accounts in the same way, they, too, would appear to be in a state of bankruptcy, which was a position they could not for a moment admit. It was the way in which the items should be separated. He showed that several accounts ought to be struck off, if a true representation of the state of the Society was to be rendered. It would then, he argued, appear in a much more favourable light than it did at present. The Commissioners had put on record their satisfaction at the great decrease which had been made by this Society in the way of expenditure. The 4s. rent put down in the published balance-sheet of the Society, was merely a nominal matter, simply a recognition of the Commissioners' right as landlords of the property. Instead of owing to the Commissioners £4000, as Mr. Godson represented, this Society owed not a single farthing. It was necessary that the Fellows should know their position with regard to the rent to the Commissioners. The sum fixed as rental was £2400, or such less sum as might be their surplus. If their surplus was nothing, they did not owe the Commissioners a farthing. It was not till the summer of 1866, that the Commissioners' rights as landlords would begin to arise. That was five years after the agreement. If at the end of ten years after the agreement, the Society had in no single year paid the £2400, then the Commissioners had a right to step in and claim their rent. For the first five years it had so happened that they had paid rent, a very considerable sum of rent, nothing this year, a small amount last, £3000 in the Exhibition year, and £1000 the previous year; therefore, if the Society by hook or by crook was able to pay the Commissioners £2400 in any one year of the second five years, the Commissioners' right to forfeiture would not arise.

Mr. S. H. GODSON, in answer to what fell from Mr. Bate-

man, said he had yet to learn in what way he was connected with the observations of his son. He then attempted to show the position of Chiswick at the time it came into the hands of the Kensington Board. Chiswick was £11,000 in debt, and he mentioned the circumstance to the Council, and asked for a committee of investigation. Several noblemen were present, and acquiesced in the motion, saying that if there was anything to explain it should be explained, and if there was anything to be laid before the Committee by them it should be laid before them. Their notion was, that the more the matter was inquired into, the better they should be able to get out of the difficulty. That was simply the object, he understood, of the motion now in reference to the affairs of this Society. Five of the members of that Committee became personally responsible until the debt was paid off, and it was paid off by reducing the salaries of the officers £700 a-year—by cutting down a fruitless expenditure. He then went on to argue that the Commissioners, who, he said, were bound to spend as much on the Kensington Gardens as the Society had not done so. The rental fixed for the grounds was more than they were worth; therefore he wanted to know where was the liberality of the Commissioners. Certainly the Society did not pay the rent, but at the end of five years the Commissioners could take the property, on which the Society had spent upwards of £70,000. The time, he thought, really had arrived when there should be an understanding between the Society and the Commissioners.

Cries of "Divide" were raised when Mr. Godson resumed his seat.

Mr. A. F. GODSON begged to say that as the propriety of his using the words "true" and "honest" with reference to the accounts had been questioned, he used them in the sense of their own bye-laws, which provided for a full, straightforward, and clear account being rendered, and he had shown it was not a full, straightforward, and clear account.

The CHAIRMAN claimed the right to say a few words. After explaining how he came to occupy the chair, and that he had considered it his duty to encourage discussion from all sides, he congratulated the Society upon the unanimity with which he believed the Report was about to be adopted. The opposition arose, as it were, from a family party. With the exception of the three gentlemen—Mr. Godson, sen., Mr. Godson, jun., and Mr. Weston—they had had no speeches in any way reflecting on the Council. Mr. Godson, sen., had attempted to excuse his son using strong language on the ground that it was impossible to put old heads on young shoulders. Mr. Godson was a friend of his, and he had to offer him his congratulations, as he, too, appeared, although advanced in age, to have a young head on his shoulders; for, if anything, he had been more energetic, and shown more warmth, than his son [laughter]. With regard to Mr. Godson, jun., he (the Chairman), like everybody at the meeting, deplored the language he used. He possessed great fluency, and could turn figures from what they were intended to represent to something else he wished them to mean. That, in a young financier, was no inconsiderable merit. He had fifteen years' experience of parliamentary life, and he would recommend Mr. Godson, jun., if he wished his facts to be taken as true, to clothe his remarks with less suggestions of bad motive. He had to thank Mr. Bowring for his explanation—an explanation which he gave last year. It proved that nothing was so difficult as to explain a matter to persons whose whole object in life appeared to be not to learn, and who persistently declined to be informed. Mr. Godson objected very much to the form in which the accounts were drawn. Mr. Bowring likewise objected on the same score; and if he (the Chairman) chose he was at liberty to object, as they were put into the present form long before he had a seat at the Council. This, however, might be said, if aught were wanted in their justification, the archives of the Society would show that, at the time the form was adopted, Mr. Godson, sen., held the post of Finance Chairman. He hoped, however, as an objection was raised, the matter would be looked into. As to the *conversazione*, he fully justified that step.

The motion for the adoption of the Report was carried by a large majority.

Some questions affecting the admission of members and

the public into the gardens having been answered, the Scrutineers reported that Sir Joseph Paxton, Sir Arthur Buller, M.P., G. F. Wilson, Esq., B. T. Brandreth Gibbs, Esq., and Mr. Andrew Murray, were elected new members of Council; that the Duke of Buccleuch was re-elected President, John Kelk, Esq., Treasurer, and W. Wilson Saunders, Esq., Secretary.

This closed the business of the meeting. On the motion of Mr. Godson, sen., seconded by Sir A. Scott Waugh, a vote of thanks was accorded to the Chairman; and on the motion of Mr. Godson, jun., seconded by Mr. Bowring, a similar compliment was paid to the Scrutineers.

Inner Temple, Feb. 17, 1865.

SIR—As some misunderstanding has arisen from Mr. Edgar Bowring's complaint that I did not include the sum of £1045 (the receipts in the South Kensington Gardens on the non-exhibition days) in the sum derived from the exhibitions, I am desirous of offering an explanation. In my criticism of the accounts I followed the divisions given by the Council, dividing the whole year into exhibition days and non-exhibition days. The attention of the meeting was drawn by me to the former only, as I considered the Council had the greatest control over those. As the expenses at South Kensington are necessarily very heavy (indeed our subscriptions go to meet the extra expenses there and at Chiswick), no criticism on this point was made of them. Should Mr. Bowring wish to bring the receipts on the non-exhibition days to balance the loss on the exhibition days, surely he must also bring in the sums expended by the Society to procure those receipts. Should this be done the deficit becomes greater. In my analysis the account stood thus—

Exhibitions..... Receipts, £1483 ... Expenses, £2454 ... Deficit, £971

Mr. Bowring would put it thus—

	Receipts.	Expenses.
Non-exhibition days .....	£1045 .....	.....
Exhibitions .....	1483 .....	£2454
	2528	2454

but adding the expenses of the non-exhibition days we have the full account,

	Receipts.	Expenses.
Non-exhibition days .....	£1045 .....	£3692
Exhibitions .....	1483 .....	2454
	2528	6146

thus leaving a deficit of £3618. There is only one other point I pray your permission to answer. The noble Chairman, in his reply on my observations, seemed to think that I complained of the system of accounts as fixed by some committee on the establishment of the South Kensington Gardens. My complaint, on the contrary (in which I did not stand alone), was that there was no fixed system of accounts. In the course of the debate on my amendment it was proved that the form of the accounts had been altered more than three times in less than five years. Surely this could not happen on a "fixed" system.

I remain, yours truly, A. F. GODSON.

#### SPRING MEETINGS.

We are requested to state that, in consequence of the Spring Meetings of the Royal Horticultural and Royal Botanic Societies having been fixed for the same dates, the Council of the Royal Horticultural Society have arranged that the South Kensington Meetings of March 18th and April 8th shall be altered respectively to March 25th and April 15th, or one week later in each instance.

#### WEEKLY SHOW.

THE weekly Show on Saturday, the 18th inst., was more interesting than any of its predecessors, though, like them, very deficient in the speciality set forth in the programme, there being only two small collections of Heaths in small pots shown by Messrs. Lee, of Hammersmith, and Mr. J. Fraser, of Lea Bridge. The latter also exhibited *Hovea pungens*, with beautiful deep blue flowers. Messrs. Lee had, in addition, a nice double Chinese Primrose, called *erecta flore pleno*; *Dendrobium cerulescens*, with seven fine spikes of flowers, and the white-and-yellow-flowered *Coleogyne cristata*, in fine condition. Mr. Hall, gardener to

Her Serene Highness the Princess Edward of Saxe Weimar, contributed three baskets filled with Winter Aconites and Snowdrops, interspersed with Ferns; also Violets; and Mr. Bull an interesting collection of new Japanese plants, including *Euryas*, *Euonymus*, the female *Aucuba*, &c. From the same exhibitor came *Imantophyllum cyrtanthiflorum*, and eight very good standard Orange trees, in fruit. Major Trevor Clarke sent cut flowers of forced *Chrysanthemums*; Mr. Batley, Rugby, bouquets for sale, and cut *Camellias*. Grapes were represented by three excellent bunches of Muscats, and West's St. Peter's, in good preservation, from Mr. Tillyard, gardener to J. Kelk, Esq., Stanmore Priory. As it was "all prizes and no blanks," it is merely necessary to say that the above objects received first and second-class certificates.

#### THE EXHIBITORS' MEMORIAL TO THE COUNCIL OF THE ROYAL HORTICULTURAL SOCIETY.

I DID not, though invited, attend the exhibitors' meeting in London. As regards flowers in general, I have no interest in them. In allowing my name to be attached to a remonstrance, I desired it to be confined to the Saturdays' National Rose Show. The National Rose Show is in a great measure national property. It stands, therefore, in a different position from all other exhibitions. In my friendly letter in a contemporary, whilst pointing out the inconvenience of Saturday as an exhibition day, I expressed a hope that the Society would reconsider the matter as regards the national flower. Unfortunately, as I think, they did not do so. The powerful names attached to the remonstrance in no way represent the number of nurserymen, gardeners, and amateurs, who object to Saturday shows; and who, though they have not signed the memorial, will not think of attending Saturday shows.

Saturday in most of the towns of England is either a market day or a day of greater business than any other day. On Monday, the higher orders drive into the country town, on Saturday the middle and lower classes go. Tradesmen do not like to be absent from home on either of these two days. Both days must encroach upon the Sabbath day; and glad am I to see that the trade and gardeners will not have their Sunday encroached upon for greed or glory. Even "F. R. H. S." allows it is a "mistake." I pointed it out to them through the medium of the press. Why did they not do what sensible men in ordinary life do, "correct their mistake?" Talleyrand said a "blunder is worse than a crime." This arrangement, being a great blunder, must be a great crime. The crime is committed against the Society itself. It would have been something in mitigation of the blunder if the Society, when remonstrated with, had said distinctly, "We will alter it another year to some more convenient day." It would have been still wiser had they said, "We will alter it at once." What is the issue? I have received a letter from the Crystal Palace Company, saying that they will adopt all the suggestions of the Exhibitors' Society. Can their suggestions then be inordinate?

I do not think the Royal Horticultural Society have a right to hold the National Rose Show on a Saturday. I admit they have a right to hold all other shows on that day, but the sequel, I think, will not endorse the appointment. Why, even the London nurserymen, and gardeners living close to London, have signed the remonstrance! Had a petition been sent round the kingdom for signature I believe it would have been universally signed. I should really be sorry unjustly to injure the Society. I would much rather read of its prosperity. Its prosperity greatly rests upon the good will and assistance of the nurserymen, gardeners, and amateurs of the kingdom. It is to see their commodities that people go in greater numbers to the Society's garden than they would otherwise do. There is still one thing they could do—put the great shows on a Wednesday, and hold the other shows on a Saturday and Wednesday alternately for one year. "F. R. H. S." appeals to the generosity of exhibitors to go this year on the Saturdays. Such would be a very unwise act; for it is plain that if success attended the Saturday shows they would not be altered to another day. The argument then would be, "See how well they succeed!" I do not like *meutes* myself, but there is always something wrong where they occur,

As regards Saturday, it is not that "I won't go, but I can't." The parishioners will say:—

"By our pastor perplex'd  
We cannot determine;  
'Watch and pray,' says the text.  
'Go to sleep,' says the sermon!"

My "best" man is the parish clerk, and he will say "Amen" in the wrong place!

I should not think the Exhibitors' Society have sent a schedule "with their own value of the prizes affixed." At least I have not seen any such schedule. Probably it relates to Saturday certificates. "F. R. H. S." asks, "What is the end of this rigmarole?" I will tell him: If he cannot persuade the Society to alter at least their grand show days from Saturday to any other day than Monday the nurserymen, gardeners, and amateurs will not send their commodities; and "the large proportion of Fellows," simply lovers of pleasure, gay meetings, and crinoline exhibitions, will have to make out their holiday with "croquet, quoits, and Aunt Sally!"

In conclusion, I am glad to see the names of Sir J. Paxton, Mr. Wilson, and Mr. Brandreth Gibbs, a good administrator in agricultural matters, elected into the Council of the Royal Horticultural Society. One pennyworth of common sense is worth a pound of wit!

I am a remonstrant chiefly, but not only, as regards the National Rose Show, and I am sure that that Society would never have been given up to the Royal Horticultural Society had it been supposed possible that Saturday would have ever been fixed for the exhibition of our national and much-beloved flower.—W. F. RADCLIFFE, *Tarrant Rushton, Blandford.*

SIR.—It would be very easy to show that your correspondent, "F. R. H. S.," is either a partisan and friend of the Council, or knows nothing of the subject in dispute between the Council and the exhibitors. I am told the Council in their report have made a charge against the exhibitors of dictation, which I and every member of the Exhibitors' Society repudiate. When we get the report of the Council we can reply formally from our Committee. Your correspondent writes as if the Council were trying something new for the first time. Why, have they not had novelty enough, and have they not been going from bad to worse for the last three years? Nothing but novelty, and no effect! Now they have the astounding novelty of an Azalea show on the 17th of June, a month after they have passed their best blooming!

Can the Council expect the exhibitors to join them in all such vagaries? And can they wonder that we should send in a remonstrance stating our inability to co-operate with them, and refusing to exhibit unless some consideration is shown for the convenience of those on whom the exhibitions depend for success?—A MEMBER OF THE EXHIBITORS' SOCIETY.

### A HOWL.

A HIGHLY distinguished, but in his latter days a somewhat eccentric, nobleman that I knew once as one of my parishioners, used to take great delight when on his daily drive in getting out of his carriage, standing in the middle of the road, and literally howling at the top of his voice. What he did it for no one could tell. Whether to show that the voice that once held entranced both Houses of the Legislature, that made many a bewheeled jury think "the worse the better reason," was still unsurpassed in volume, though the mind that directed it was not what it once was; or whether he had some special grievance rankling in his mind, and that he thought it better to vent it this way than on any of the inmates of his house; or whether it was intended as a protest against all and everybody, was never known; but it was evidently a great relief to him, and he who went out testy and cantankerous, snapping the head off any one who spoke to him, was after this more amiable and tractable. Of course his family gladly indulged the whim; for, as the big fellow whose little wife would beat him said, "It pleases her and doesn't hurt me in the least," they felt that what was a relief to him was a boon to them. Well, I want to have a howl. I have a grievance—it is not against any one

in particular, but I do know why I make it; and although I may not do anybody any good, I shall certainly, as some people wickedly say of homœopathic medicines, not do them any harm. It will be a relief to my mind to give it, and who knows but some one may catch up the echo? My howl—(stand out of my way, good folks who think all beauty is concentrated in a Fern, an Orchid, or a fine-foliaged plant)—is about the neglect of florists' flowers generally, and of the Gladiolus in particular, in and about the metropolis.

Let me be understood first of all in what I mean by florists' flowers. I will take the term, not in its enlarged but restricted sense. I am aware that under any definition of a florists' flower you must include the Rose, the Dahlia, the Pelargonium, and the Azalea; but they are not neglected—No: the flowers to which I specially allude under this title are the Auricula, Pansy, Pink, Carnation and Picotee, Ranunculus, Tulip, and Gladiolus; and the position I wish to advance is this, that there is not sufficient encouragement from any quarter given to these flowers in London, and that hence they will rapidly go out of cultivation; for although those who are really lovers of any particular flower will grow it with no prospect whatever before them, of exhibiting but simply for their love of it, yet I maintain that so great is the influence of horticultural exhibitions, that just in proportion as a flower is encouraged and shown will be the increase of growers of it, and the estimation wherein it is held. Had the Dahlia not been encouraged as an exhibition flower would it ever have reached the high perfection to which it has attained, and be valued, as it is everywhere, as a fine autumnal flower? What was it in times past that made the Auricula, the Carnation, and the Tulip what they became but those exhibitions at "The Horns," Kennington, at the Surrey Zoological Gardens, and of the National Floricultural Society? And why is it that now one after another is abandoning these? Because people think far more of the most trumpery novelty in "bedding-out plants" and will give encouragement to anything save those flowers of which the cultivation is within the reach of any amateur who, with his little plot of ground, desires to grow his favourites.

I believe a great deal of this arises from laziness. No florists' flower can be properly grown without a great deal of trouble; and a small garden may be made very showy, glaring, and hot-looking with Tom Thumbs, Verbenas, &c., without either much skill or trouble. Look, as I have often done, at the artizan with his frame of Auriculas, his stage of Tulips, or bed of Pinks. See what care and skill he shows in managing them, how all the year round they are in his mind—his first thought when he goes out to his work in the morning, his last before he goes into his home at night, and then tell me, What are you doing to encourage this man now? He was, many a time, a raiser of seedlings; he had of course (as who has not?) exaggerated notions of their excellence; but when he did satisfy the critical eye of a Turner or Keynes, and saw Smith's True Briton, or Jones's Jolly Tar, or Robinson's Fair Ellen in the catalogues, was he not a proud man? And when he got his few pounds for his child, and brought it home to the good dame instead of drinking it out at the "Blue Bull," did she not forgive him for taking the blanket off his bed that cold frosty night to put it on his frame (for I have known such things done)? Yes, I trow; and may we not howl over the good old times, which seem to be gone from us for ever in these days of Scarlet Geraniums and polychrome beds?

But it may be asked, Do not the Royal Horticultural and Botanic Societies, and the Crystal Palace, encourage the growth of these things? They give prizes for them undoubtedly, but in very scant measure, and in some of them far behind even the provincial shows; and it is not two or three prizes, for which amateurs have, perhaps, to enter the list with nurserymen, that will really encourage the growth of these flowers. Let me take one of the newest and at the same time easiest grown of florists' flowers—the Gladiolus, and let me beg all whom it may concern to read the following, occurring in an article on that flower in the "Florists' Guide." The writer hails from "sweet Dublin," and I know him to be what he claims there to be, one of the most successful growers of the flower, and one of the most enterprising purchasers as a necessary consequence. "And I may here observe that we have good prizes to compete for: for autumn, 1865, a silver cup value ten guineas, a second

ditto worth eight guineas, with good third and fourth money prizes, are offered for the best thirty-six Gladioli, containing not less than eighteen varieties. I think this beats South Kensington and the Crystal Palace too." I should think so too. Why, at South Kensington no prizes are offered, and at the Crystal Palace nothing higher than two or three pounds, and for these all have to compete together. Why, they do these things better at Brighton; there they give £3 for their first prize, which I am glad to say I carried off this year. And what is the result in a commercial point of view? The cheaper and easier-grown Gladioli find a sale about London, but none of the more expensive kinds.

What is to be done? As to the Royal Horticultural Society ever doing any good for floriculture I must confess my most decided doubts, and those who think otherwise are of a more sanguine temperament than I am. My own opinion is that some fresh organisation is wanted. The florists should meet together and talk over their grievances, and try what plans can be adopted to remedy them. National societies, as they are called, have proved a failure. At such we may have a good display; but then, they are not national; the difference in climate between the north and south of England is so great, that when flowers are out of bloom in the one they are only just coming in in the other. Take, for example, the National Auricula Show, to which, let me say, I wish all honour, especially as this year it is to be under the fostering care of that veteran and kindly florist, Mr. Headley, of Stapleford, near Cambridge. If it is held, as it has been done, on the 30th of April, nearly all the southern growers are shut out, except perhaps such as Mr. Turner of Slough, who has such a large stock that it would be difficult at any reasonable Auricula time to catch him napping. But at neither of the two National Shows that I have attended could southern growers have a chance; while last year, so backward was the spring, that the more northern ones had not their collections in bloom. Hence I would advocate a society, irrespective of any party, clique, or set of men whatever, for the purpose of seeing if something cannot be done for floriculture in and about London. See how Tulips, Carnations, Picotees, and Pinks are going out of favour and cultivation; and if we do not wish all florists' flowers to share the same fate something must be done.

And now I have had my howl. Much good may it do me, say some. I have, however, I think, pointed out a defect in our present horticultural arrangements, and hope some one may agree with me.—D., Deal.

### STRAWBERRIES.

IN page 112 of THE JOURNAL OF HORTICULTURE, February 7th, is an article by "A FRAGARIAN," headed "La Constante and Some Other Strawberries." That article refers to my quotations from Mr. Taylor's note, and I will now reply to "A FRAGARIAN'S" article, in which there are seven paragraphs.

First paragraph. It must be a long line of Strawberries to produce 250 runners, judging by the slow running of La Constante here, during the four years that I kept it. If the reader will refer to Mr. Turner's catalogue, I think he will see it stated, that in his fine land it is a slow grower. I first gave it to Mr. Rivers about two years ago, and also to Mr. Turner. The former was this year obliged to send to France for runners. When I sent it to them, I was obliged to send some offsets with the runners, on account of the difficulty of obtaining the latter. When plants are dis-fruited, they usually run freely, and at once; but, even on this plan, I found a difficulty in obtaining runners. Strawberries may, like some Roses which are not hardy in all soils and situations, be hardy in land suited to them. The British Queen is an instance. Again, Strawberries which otherwise suffer much, may be hardy if well established before winter sets in. In a word, from slow and late-running, they require two winters' and one summer's nursing before you can crop them, unless you have a sufficient number of plants to bed them, and depend upon numbers for crop. This, of course, can be done, and the plants may be thinned for the next year. When La Constante is established it is hardy, though not so hardy as Eliza and Wonderful. Early running and quick establishment are *desiderata* in England, as stated in

an able article by Mr. Cox, in the "Florist," of February. Substituting the word "straw" for "grass," I assent to it cordially. I found here that La Constante after being nursed for this long period gave me one good crop, but the plants sickened, did not run, and were worthless the next season.

Second paragraph. I regret much the loss of Mr. Nicholson, a most kind man, to whom I am indebted for Wonderful. The runners sent here from his establishment were always first-rate. I had some La Constante from him, as well as from France, but the result was the same. No man is more willing to acknowledge its merit as a fruit. Its flavour is *svi generis*. Its form, both as to plant and fruit, is perfect. "A FRAGARIAN" concedes what I have stated. He says: "It requires good and patient treatment, for it puts forth its runners so late in the autumn, that they are not able to gain size and strength sufficient to bear fruit the following summer." Life is short, and this process is too slow.

Third paragraph. That the process is slow, observe the following in proof. He says: "About Christmas they [that is, the runners planted 6 inches apart] are mulched with strawy manure, care being taken not to smother the plants. In the August following [that is, when the plants are twelve or thirteen months old] another trench is dug about a spit deep. The yearling plants are taken up carefully with a trowel, and they are planted in ~~the~~ prepared ground in patches of two or three together, a space of 14 or 15 inches intervening between the patches. They are mulched again at Christmas. The following summer, plants so treated have never failed to produce an abundant crop of first-rate fruit." I doubt not this at all. Still La Constante suffers in burning summers; the fruit is all exposed and baked, and being ripened simultaneously, you must eat it as fast as you can.

Of course, "A FRAGARIAN" has told us by a periphrasis, that his land is first-class, for he speaks of removing two-year-old plants, a practice that will certainly not succeed in any land that is not naturally a Strawberry soil. Still it is fair to say, that I have known two-year-old British Queens removed, and crop heavily; but this was in the very finest and deepest land, genial to the variety.

Fifth paragraph. As regards Empress Eugénie, I admit that in cold wet seasons, being so large, it is not good, but it is a noble production. Excepting the Frogmore Pines, it is the best of all the very large sorts. Strawberries which have travelled a distance are very different from those tasted *in loco*. We must have quantity as well as quality, and both in one. A beggar once told me there was "no taste in nothing."

Sixth paragraph. I admit the excellence of the Strawberries named; but some of them are only suited to first-class land. I should not say Elton Pine (called in France pickled Gherkin) is the best late Strawberry. It is hardy, handsome, and useful. The Frogmore Pines are far in advance of all other late sorts. In evidence of its fine constitution, I may observe that I fruited heavily, they running at the same time, my two-year-old-plants kindly given me by Mr. Turner. I sent Dr. Hogg the second picking, and he can tell whether they were large and good. The plants brought their heavy crop to perfection, and are strong for 1865.

Seventh paragraph. I agree to this. We cannot form a just estimate till we get our own runners put in sufficiently early to be established before winter sets in.

Lastly, in future, I shall take no notice of any remarks on my contributions, unless the writer give his name and place of abode. I never myself pay the slightest attention to such communications.—W. F. RADCLIFFE, *Tarrant Rushton, Blandford.*

### CLIMBING DEVONIENSIS ROSE.

HAVING read in your Journal of a climbing Devonensis Rose sent out by Mr. Curtis, of Torquay, it may be interesting to your readers to know the true history of its origin.

In the year 1857 I budded some of the old Devonensis on the Celine stock, when on the following year many of the plants made shoots from 3 feet to 9 feet in length. I have now in my stock one of the original plants I obtain my

buds from, it having withstood the severe winter of 1860-61. Many of your readers will be inclined to think there are two varieties of this magnificent Rose. This I beg to contradict, having supplied Mr. Curtis with buds as well as plants.—S. J. PAVITT, *Rose Cottage, Bathwick, Bath.*

### HARDY FERNS:

HOW I COLLECTED AND CULTIVATED THEM.—No. 10.

My next Fern-tour, after Cornwall, was to the Lakes.

I seemed to have left in the south the monuments and recollections of the past, to bask for a time in the roseate hues shed back upon the world from the great intellects that had so lately gone down amidst the Westmoreland hills. At the Carlisle station Wordsworth's little grandchild met me with a basket of Grapes. I took them with me into the land so sacred to his memory; and not to his memory alone, for the whole district seemed haunted by spirit shapes, flinging at me choice bits of sparkling wit or caustic humour, with here and there strange touches of tender melody. Sometimes I seemed to hail Professor Wilson, sometimes Coleridge; while Southey and Wordsworth gave me more friendly greeting, lingering with me by every lake and tarn, speaking to me out of the rushing waterfall, setting their own sweet rhymes to Nature's harmonies.

Our first halt was at Windermere, from which we made many excursions amongst the hills. We found *Hymenophyllum Wilsoni* at Dungeon Gill Faece, to which we drove by Loughrigg Fell, seeing a curious sort of haymaking going on by the way, where men took the place of pitchforks, and cast the hay "abroad" with their hands. In some parts of the Pyrenees I have seen the same custom prevail, and when the hay was made it was gathered together in a large sheet, tied up, and carried away on the heads of women to the rick. It is rather a scramble to reach the *Hymenophyllum* at Dungeon Gill, but mine host at the little inn is expert in giving help, and, moreover, he is a botanist, and found us many rare wild flowers that would have escaped a less experienced eye. The inn is far removed from any other habitation, and the master told me that he found botany the greatest resource during the many anxious days he passed, before the Lake season really set in, waiting for visitors who would not come. How great the poor man's anxieties were his keen watchful eye, his pale anxious face, too fully denoted. He had been in service; this inn was to be let; he married a good girl whom he had long loved, and began life hopefully. The first year all went well, but by-and-by another inn was built in a more convenient situation. Visitors dropped off to the rival house, and the poor young couple were in deep fear for the result. When I remember Dungeon Gill in its drear loneliness amongst the hills, I fancy I see the wistful eye looking up the long road for the help that visitors alone could bring. I longed to make every one I met drive over to the inn that stands waiting for the "Good time coming," within hearing of the tumbling waters where *Hymenophyllum Wilsoni* can be found for the seeking, to reward them for their pains.

We drove back to Windermere by Grasmere, Rydal, and Ambleside. As we got near the church at Grasmere the driver looked over his shoulder at us and said, "Would we wish to alight at the church? 'Parties' mostly liked to say as they'd seen Wordsworth's grave." So we alighted, and stood beside the plain stone slab, on which was engraved but the two words "William Wordsworth;" yet what magical words they were! They seemed to open a long vista down which troops of "parties" were slowly pacing to and fro the poet's grave—"parties" from every quarter of the globe, princes and peasants, statesmen and poets, old men and little children—all drawn to the one solemn spot where Nature's poet lay so calmly sleeping amidst the scenes he loved so well. What was it in the quiet poet that moved all hearts? Was it the "touch of Nature" that "makes the whole world kin"—the Nature natural, yet very human too?

Ambleside was busy as we drove through. Children with happy faces were running about with every sort of quaint device, made in rushes and flowers, which they were to put up in the church at evening service, in honour of the ancient custom of Rush-bearing—a custom for which no

reason is now given. May it not be the remains of the custom, which prevails abroad, of strewing the churches with sweet-scented leaves and flowers, when there is an "Exposition of the Blessed Sacrament?"

I went to Grasmere church on the following morning, but I thought the quaint devices wanted the children's faces to set them off. It is a lovely drive from Windermere to Ulleswater by Troutbeck and Kirkstone Pass. On this drive I first saw the *Allosorus crispus* in perfection. Hitherto I had only possessed little roots I had bought for 1s. 6d. each, which I had cherished as great rarities; but on this day I saw it in immense quantities, and I was told it was used by the poor people to heat their ovens with. What a surprise it was! I first discovered a few plants in a wall: I begged the driver to stop while I dug them out. He laughed and said, "Wait awhile, Ma'am, you'll find better than that." A little further on there were some small tufts by the side of the wall. I stopped the driver again, and again he laughed and said, "Wait." So I waited till we arrived at the inn at the top of the pass, and there it was growing everywhere; but there is such a thing as being embarrassed with riches, and it was difficult to decide which to take. I did what I advise other Fern-lovers to do; I packed up a large hamperful, and sent it off by rail, home. The hostess of the inn showed me also some *Asplenium viride*, not in tiny plants as I had always seen it, but in large beautiful masses. I bought a large clump for 6d. I asked if I could find it for myself. "Oh, dear no! quite impossible." It only grew in the most inaccessible places where no one less brave and active than her spouse dare venture. I do not think I quite believed this; but the horses were rested, so we drove on to Patterdale—beautiful Patterdale!—surrounded on all sides by hills, reflecting themselves in the clear waters lying at their feet.

I cannot write of Patterdale without a greeting to our good friend "Jack," guide, herbalist, fernist, umbrella and watch mender, glazier, &c. I made acquaintance with Jack at once, and asked of the Ferns. Could he take me to find the *Asplenium viride*? "Impossible;" it only grew in the most dangerous places; but he had a store of plants, found long ago, that he could show me. I was taken to the spot, and saw about fifty plants, very faded and blue-looking as if just transplanted. I asked Jack if this were not the case. "Well, yes;" he had brought them from his own to the inn garden. Jack offered me a part of his spoil. No, I must find some for myself. Would I take him with me? Certainly, and give him an extra shilling if I found plenty. So the next day we set off for the ascent of Helvellyn by Grisdale Tarn. Half-way we ascended the rocky path, down which little streams were trickling here and there: presently there was a cry of "Found!" and I saw my first plant of *Viride* growing wild; it was peeping from under a dripping boulder of rock, like a green lizard. I could only find it in the places where the trickling stream kept perpetual moisture, and yet where the sloping hill and pebble bed made perpetual drainage. I learned the peculiar habit of *Viride* on this particular morning, and I never allow any stagnant moisture to be near it; if I do, the fronds rot and drop off. The views from Helvellyn are magnificent: they steal on the waiting eye, as you ascend higher and higher, in new and varied forms of loveliness. Lake after lake, like silver purified, nestles amidst these ever-changing, ever-lasting hills, over which a million lights gleam and haste away. Ulleswater, Windermere, Esthwaite-water, Coniston, Bassenthwaite, and Thirlmere were visible; the Ayrshire mountains, Solway Firth, the sea, and range after range of mountains, the nearer ones seeming as soft emerald-coloured velvet, those far away dark blue and sober grey. But the ascent of Helvellyn is not all pleasure; it abounds in treacherous bogs, in two of which one of our horses floundered.

The day after the ascent of Helvellyn I had a private hunt for *Viride* in an opposite direction, and I was most successful, finding quantities in the wake of the trickling watercourses down the hill, but not one root did I find in any other situation. I did not once find it mixed with *Trichomanes*, which proved to me that these two Ferns require totally different situations in cultivation.

On the mountain side, where I found the *Asplenium viride*, I discovered the very beautiful *Cystopteris* I have mentioned

in one of the earlier chapters. I have named it "Elfina." I have shown it to a great authority on Ferns, who calls it "near alpina;" but I believe the acuteness of its teeth remove it entirely from alpina, and the division of the fronds from any other named species.

The recollection of Ulleswater and Patterdale is very pleasant to me; the silver mines and the *Asplenium viride* give it an individuality of its own.

Derwentwater is also lovely, and there are many magnificent excursions to be made from it. I saw the waterfall of Lowdore at its best; the snowy waters were playing all sorts of freaks in the gleaming sunlight, sparkling with fun as they caught his rays, and darting back foam and spray from the sober rocks which stand steady and firm amidst the "muttering and sputtering" uproar. I spent one day hunting for Ferns in Borrowdale, and found *Asplenium septentrionale* on the Castle Rock, but only in very small roots. From the way in which it was growing I have no doubt that it may be found in some quantities in the neighbourhood. *Asplenium germanicum* is also to be found

in Borrowdale; but the guides are such diligent seekers they scour all the accessible places, leaving very little for timid climbers. In the neighbourhood of Castle Rock *Hymenophyllum Wilsoni* grows in abundance. It may be found in long trailing masses hanging to the damp rock.

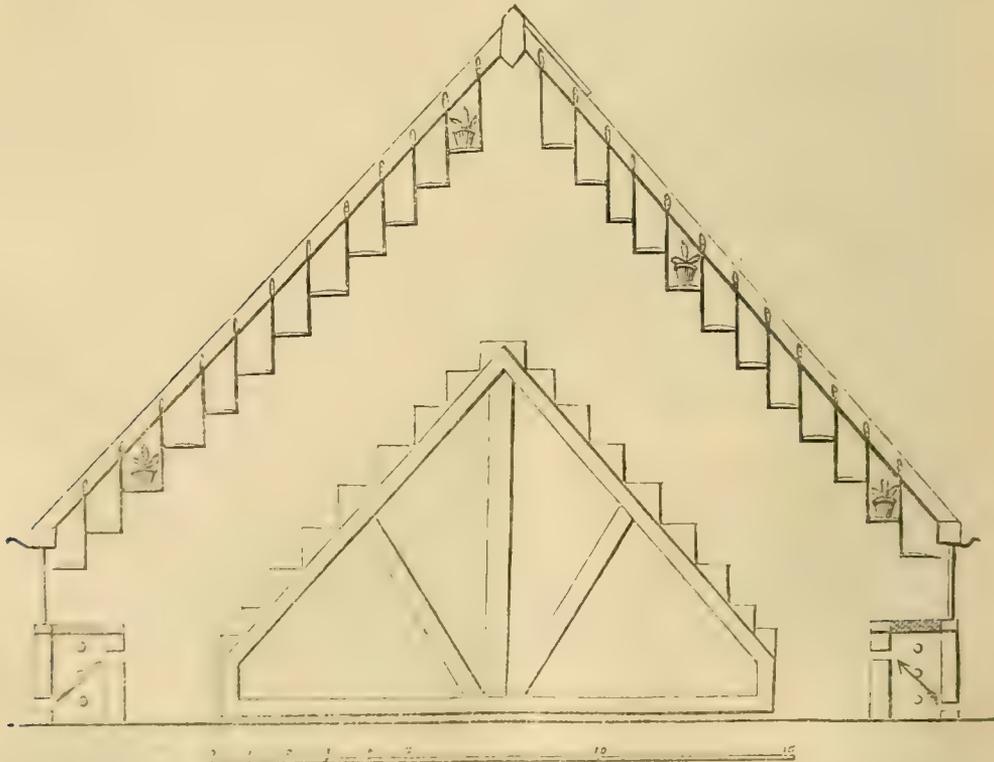

If I visit the Lakes again I hope to find both *Asplenium septentrionale* and *germanicum* about Honister Crag, where I believe it has several times been seen. Who can tell the glories of the mountain paths in the district round Honister, where waterfall answers waterfall, and bleak dreary moors melt into sweet homeland scenes; where children play about the cottage doors, and join their voices with waterfall and mountain in one grand *Te Deum*, for ever ascending from a grateful earth to the throne of Nature's God in heaven? I know not why it is that mountain districts should have so soothing a power upon the mind; but there is something in their vastness and their stillness that seems to hush all rebel thoughts, and bow the heart of the created in simple, unquestioning awe at the feet of the Creator.—*FILIX-FEMINA.*

### STRAWBERRY FORCING.

(Concluded from page 111.)

The essentials in forcing Strawberries are an abundance of light, close proximity to the glass, ample ventilation, and if possible air beneath them. Nothing is so good as shelves about 15 inches from the glass, one along the front and another at the back of a vinery. Where there is a quantity to force it becomes a question how the plants are to be accommodated. Stages when near the glass are good; but the best plan in my opinion is to have shelves fixed by holdfasts to the roof, as shown in the accompanying engravings.

The roofs are steep; the shelves inch deals, 9 inches wide, and on these are laid turves, 1½ inch thick, grass side downwards. The holdfasts are quarter-inch iron, 1 inch wide, and the end next the rafter is punched with two screw holes, and fastened to the rafter. The lower end is bent at right angles, and has a rounded threaded point that passes through a hole in the holdfast next below it, and a nut screwed on keeps it in its place. This will be easily understood by a reference to the woodcuts. Any one with a

little ingenuity will be able to have them made, and, I have no doubt, to improve upon them. The points secured are close proximity to the glass, and a circulation of air under and everywhere about the plants. Strawberries may be grown, I am aware, without shelves; but they never do so well as when near the glass, and elevated so as to receive

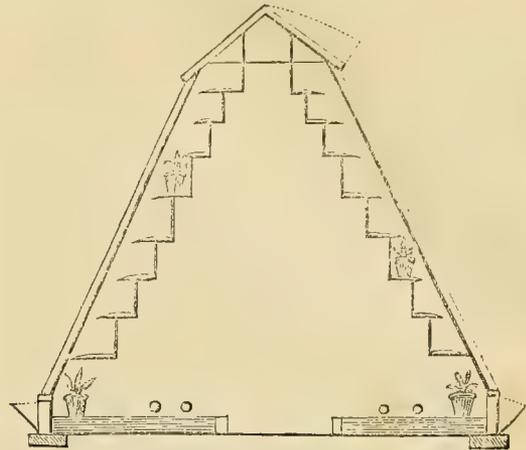

air from beneath. I have had them in pits close to the glass, but not having the undercurrent of air they did not afford nearly so good a crop as plants on shelves with air playing all round them.

When very early fruit is desired the plants should be placed on, or slightly plunged in, a bed of leaves made suffi-

ciently high to raise a gentle heat of 70°. This should be done in the first week in December, and the lights must remain off as long as the weather is fair, and only be put on during very wet periods, and even then a current of air should be afforded. Prior to this, the plants should have been rested for a period of six weeks by keeping them dry at the root in a cold frame, and exposed at all times except during very frosty or wet weather. They should, therefore, have the buds well developed by the middle of October.

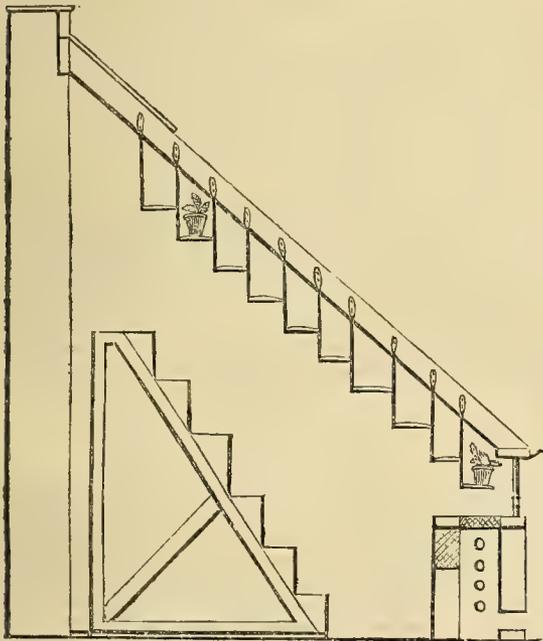

The pots being set on a bed of leaves early in December, the plants will have had an inducement to form fresh roots, and to get these in advance of the leaf-growth is a main point. This being effected, the pots should be cleaned, and any old yellow leaves taken off. The shelves are then covered with turves, grass side downwards, and the pots placed on them, the interval allowed between the pots being half their diameter. Roots will most likely be protruding through the holes at the bottom, and will soon make their way into the turves, increasing with the growth of the plants. These should not remain so long on the bed of leaves as to root into it, nor should they be taken from a bed of leaves in which they have been plunged whilst it is hot; for, in the one case, they will receive a check through a loss of roots, and in the other, in consequence of a loss of bottom heat. Care should therefore be taken to place the

but with clear intervals, and 15° on bright sunny days, every increase of temperature being accompanied by a correspondingly greater amount of ventilation.

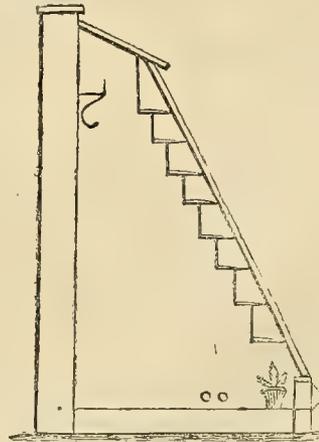

Strawberry shelves in Orchard-house.

The plants should be watered so as to keep the soil moderately moist for the first month, guarding against extremes either of moisture or dryness, for both are injurious. After this, and as the plants throw up their flower-trusses and make a large increase of foliage, they should be well supplied with water, never allowing them to become dry, though they ought to exhibit signs of moisture being needed before any is given. A gentle syringing morning and evening will refresh the plants, and at the same time secure a moist atmosphere in the house. After the first month syringe once daily in the morning until the fruit changes colour for ripening, when syringing the plants should be discontinued; but let the floor, walls, &c., be sprinkled twice daily, in order that the remainder of the fruit may swell well. Some make a point of not syringing the plants when in blossom, but I never found the flowers set any worse from a gentle bedewing of water through a fine rose; on the contrary, I fancy they set better in consequence, and are not so liable to half swell the fruit in some parts and not in others, resulting in poor uneven-shaped fruit.

Strawberry shelves in Vinery.

pots on, not in, the leaves. The temperature of the house into which they are introduced should be 40° at night, and from 45° to 50° by day, but the latter temperature only with sun. Day and night, except in very severe weather, air should be admitted, diminishing, of course, the amount at night, even in mild weather, and increasing it with sun heat. It is a good practice to admit air both at top and at the lowest point of the house; and if the air admitted pass over the hot-water pipes or heating-surface anything like chilling the plants will be prevented. The air should be given as early in the day as practicable, closing early so as to catch or retain as much of the sun heat as possible. For the first month a minimum of 40° is the proper temperature; a month after their being brought into the house the temperature may be increased to 45°; in another fortnight to 50°; and a fortnight later, or two months after introducing them, it should be 55°. At this the temperature is steadily maintained until the flowering is past, when the minimum may be increased to 60°. The maximum temperature will be regulated by external influences. On dull days a rise of 5° above the night temperature is to be allowed until the blossoms are set, 10° on days somewhat cloudy

Strawberry shelves in Peach-house.

After the fruit is fairly set every alternate watering may be of liquid manure made of half-rotten cowdung, and tolerably strong, adding a peck of soot to every sixty gallons of liquid. The liquid manure and all water given should be of the same temperature as the house. The plants should be kept well watered daily. At the time of flowering they should be gone over, and any that do not promise a crop had better be put outside, and their places filled up with something better. In introducing plants it is well to be able to discriminate between those which are likely to afford a crop and those which are not.

To prevent the fruit from hanging down over the sides of the pots, and the fruit-stalks breaking, a piece of twine is strung on the sunny side of the pots, about an inch above the rim, and on this the stems rest. This is a good practice when the crop is heavy and the stems long, but unless the stem be drawn by hard forcing the strings are not necessary, for the fruit swells all the better when the stems are bent down, the fruit touching the ground on a level with, or a little below, the rim of the pot. The first crop of fruit, presuming the plants to have been treated as above, and early kinds employed, will be ripe in March.

Successions may be obtained by introducing a batch of plants into a cold frame, or pit, at the same time as the first are taken into the house, putting them on a bed of leaves for a fortnight, then setting them on shelves in a vinery or other house having a night temperature not exceeding 40° by fire heat. At the time of removing them a batch of plants should be placed in the frame as before, and so on, working until the middle of February with the earliest, when a batch of Keens' Seedling may be introduced, and also Wellington and Oscar, and a month later the British Queen and other late sorts, the last lot being introduced about the middle of April. It is not necessary to place the pots on a bed of leaves after the middle of February, nor before that time if the pots are well filled with roots, and the buds well developed; but it is desirable to have them in a cold pit, frame, or house for a few weeks previous to introducing them into the house where they are to fruit. There is no better place than a cold vinery, or orchard-house, where they will be kept rather dry until wanted, or during winter if they remain there so long.

Where there is a number of Peach-houses and vineries that are started at intervals, no difficulty will be experienced in forcing Strawberries, a quantity being kept ready in cool frames, or houses, to be drafted into the vineries and placed on shelves as the houses are set to work, the temperature required for forcing Vines suiting Strawberries exactly. I can remember the time when it was very common to force Strawberries in Pine-stoves, introducing them at once from a cold frame into a succession-house, with a temperature of 55° or 60° by night, and keeping them there until the fruit was set, when they were introduced into the fruiting-house, the temperature being 65° at night, and from 75° to 80° by day. Roasted in this way, I have known a fair crop obtained, the Roseberry being the favourite; but now we must have a good many mouthfuls, and of good quality, instead of a taste. This can only be effected by bringing on the plants gradually, and not forcing very hard until the fruit is set; and not then except to obtain fruit very early. A temperature of 60° from fire heat is as much as the Strawberry will bear.

I need not enter upon the cultivation of Strawberries in vineries, nor treat of successional crops, an epitome of the temperature above will suffice. For the first fortnight the heat should be 40° by night, 45° by day; during the second fortnight, 45° by night, and 50° by day; in the third fortnight, 50° by night, and 55° by day; in the fourth fortnight, 55° by night, and 60° by day; and these temperatures should be maintained until the fruit is set, when it may be increased to 60° by night, and 65° by day. All these relate to temperatures from fire heat and on dull days. On cloudy days having clear intervals the thermometer may read 5° higher, and on bright days from 10° to 15° higher, when the maximum amount of air being given, it will not matter if the temperature be considerably higher, always provided that it is from sun heat.

Perhaps one of the best modes of growing Strawberries is on shelves in cool vineries or orchard-houses. They also succeed admirably on the borders of orchard-houses, providing the trees are not so close together as to shade them too much; but, taken all in all, the best place is a shelf 15 inches from the roof in front or both sides of a span-roofed house, or at back and in front of a lean-to one, the back being occupied with early, and the front with later sorts. Of the early kinds, Black Prince, Eliza (Rivers's), Eclipse, Keens' Seedling, and Oscar are excellent; and of the later sorts, British Queen (extra good in an orchard-house or cool vinery) Carolina Superba, La Constante, Sir Harry, and Sir Charles Napier. These being raised in the manner previously stated, should be kept on the borders during the winter rather dry.

About the middle of March they should be cleared of the dead leaves, and the pots cleaned and placed on the shelves, first of all putting on these, grass side downwards, a turf or turves, exactly the width of the shelf, and 1 inch or 1½ inch thick. If turves are not to be had, a lath, three-quarters of an inch wide and 1 inch deep, nailed on both edges of the upper side of each shelf, will leave on a nine-inch shelf a space 7½ inches wide and 1 inch deep. Fill this with two-thirds loam and one-third cowdung half-rotted, or rotten manure of any kind, and on this stand the pots. Keep moist until growth fairly commence, and afterwards water freely, using weak liquid manure until the fruit change colour, when water alone will do. The usual treatment given to these cool houses suits Strawberries exactly, abundance of air and light being given and a good syringing, but a close moist atmosphere should never exist.

These plants will prolong the Strawberry season at least a fortnight or three weeks, the earlier kinds being ripe in the latter part of May, and the late ones succeeding them, just when the earlier varieties are coming in from the open ground.

The plants once fruited are of no further use unless planted in the open garden, where they may yield a few fruit in autumn, and be very prolific years afterwards, especially on soils where Strawberries yield plentiful crops of leaves and but little fruit. In such I have found plants that have been forced in pots afford excellent crops when others yielded little but leaves.

In conclusion, fill the house with tobacco smoke whenever green fly appears, always letting the plants be dry at the time. Once growth has commenced never allow the soil to become dry, but keep it well watered. Never use saucers, they rot the roots by keeping the soil sour; use sods in preference, or set the pots on a shelf with laths nailed on the edges, filling the shallow trough thus formed with rich compost, for the water then drains away and the roots run both in the sods and soil. Keep near the glass, and allow the plants air above, beneath, and all round, and plenty of it. Give manure water after the fruit is set as often as you like, but let it be weak, and use no more fire heat than is necessary to maintain a steady progressive growth. Grow plants anywhere, securing these conditions, and the result will be an abundant crop of excellent fruit; but that must exist in embryo before commencing to force.—G. ABBEY.

## WARDIE LODGE,

### THE RESIDENCE OF MISS HOPE.

THIS beautiful suburban residence is situated upon an eminence overlooking the Firth of Forth, about two miles distant from Edinburgh. The mansion is a commodious structure of Grecian architecture; and from the principal windows a magnificent panoramic view is obtained of the noble estuary of the Forth, stretching like a gigantic mirror for several miles to the west, and reflecting from its glassy surface the image of many a smiling town, and village, and mansion, on its northern banks, as well as of the fertile fields and varied park and woodland scenery along its southern shore, receding behind the undulating and varied country that lies beyond, until obscured in the shadowy outline of the Ochil Hills.

The grounds around the mansion are about four acres in extent, and are laid out in a style well suited to the rich landscape with which they are brought in contrast. Running the entire length of the western boundary, which descends with a steep incline towards the sea, is a broad belt of trees serving the double purpose of shelter and ornament, and through which flows a small stream of water, leaping onward with increasing speed as it nears the sea. This has been converted into what may be called a sub-alpine garden, which in summer forms a pleasing relief from the flower garden; here are introduced nearly all the native plants usually found in similar situations, as well as exotics of a kindred nature, and so carefully and tastefully are they disposed that one is almost constrained to believe that they have been placed there by the hand of nature. At the bottom of this incline, and forming the northern boundary, is a border devoted exclusively to the cultivation of herbaceous plants, for the purpose of testing their ornamental qualities, or uses

in floral decoration. As soon as any member of this group is found worthy of a better position it is removed to the mixed flower-border in another part of the garden.

Ascending towards the flower garden the first landing is upon a finely-shaven lawn to the west of the house, margined by a semicircular border about 8 feet wide, which is set apart for the cultivation of hardy plants with ornamental foliage, and backed by scarlet Pentstemons, of which a variety called Aurora is the most effective. Here are arranged with strict regard to ornament every variegated and silvery-looking plant procurable, interspersed with crimson Plantago and other dark-foliaged plants, forming a combination at once striking and effective.

On entering the flower garden there is a magnificent border extending nearly 60 yards to the right, at the back of which runs a low wall covered with a rare and valuable collection of trellis plants. The border is about 10 feet wide, and contains an admirable collection of the most ornamental herbaceous plants, intermixed with China and Tea Roses; dwarf Dahlias, and a great variety of other half-hardy plants being also introduced in their season.

The successful arrangement of this border to produce the effect which it maintains for several months every year must be a matter of no small ingenuity, and proves what may be accomplished by a thorough devotion to the pleasures of a garden, and the cultivation of artistic taste. The effect of nearly all the attempts that I have hitherto seen in that way proved the very reverse of Miss Hope's, making one truly thankful to fall back on the "Red, White, and Blue"—namely, *Cerastium*, *Lobelia*, and *Tom Thumbs*, with which the gardening world has now become familiar, and which are so acceptable in the present day because they do not vex us with the study of scientific names, and their harmonious blendings can be acquired as easily as the rule of three.

I observed on my last visit that this border had recently been enriched with several patches of that handsomest of all winter-blooming plants which I shall here take the liberty of calling *Helleborus niger* var. *grandiflora*. The history of the plant I at present fail to remember, but it either originated or was introduced by some one in the neighbourhood of Edinburgh, and is yet chiefly confined to that locality. All the so-called varieties that I have procured from different parts of the country are only slight variations of the ordinary Christmas Rose; whereas the plant in question is double its size both in foliage and flowers, blooms fully six weeks earlier, and instead of the peduncle being one-flowered as is mostly the habit of the Christmas Rose, it produces four or five on a stem, of a rosy blush colour, and is in perfection during November.

Ascending to a terrace and passing by the greenhouse and stoves, which are rich in Ferns and ornamental-foliaged plants, we arrive at that portion of the garden allotted to the exhibition of bedding plants, which is neatly laid out in grass, and contains upwards of twenty figures. This has for several years been one of the most attractive and best-arranged flower gardens in the neighbourhood of Edinburgh. I have annually paid a visit to this lovely spot when arrayed in its summer beauty, but having read and heard much of a novel method of filling these beds in winter with German Greens of various colours, whereby a very striking effect was produced, I resolved, as I confess I had my own doubts regarding this association, to visit the place and judge for myself. Although arriving a little after daybreak in rather a wintry morning towards the end of January, I had the good fortune to be conducted through this portion of the garden by its active and intelligent proprietress, who kindly pointed out every object of interest, detailing the system of management with scientific and business-like precision. My first impression almost led me to believe that the beds were a series of beautiful rockwork formed of branching coral of appropriate colours, and even upon a more minute inspection I failed to realise almost any affinity between the vegetable so employed and that used for culinary purposes. It seems to be the variety known to botanists as *Brassica oleracea* *prolifera*, which, to use a common phrase, is tough and leathery in texture, rugged and artistical in outline, and dwarf and uniform in habit. The colours chiefly predominating are crimson and mauve, dark purple, white, and sulphur, tipped with green. These are arranged in rings

and panels in the usual way, the centre of the beds being generally filled with some pretty dwarf Conifer; and the margins as well as the divisions of the panels are composed of variegated tree Ivy, *Stachys lanata*, *Cerastium tomentosum*, *Arabis alba* *variegata*, *A. mollis* *variegata*, *A. lucida* *variegata*, and the like. The result is, that the garden, even at this gloomy season, is as brilliant in colouring and as rich and effective in display as at any period in the summer or autumn. Miss Hope had these beds planted for several years with ornamental shrubs, hardy Heaths, bulbs, and other spring flowers at a great expense; but she found that from the beginning of November to the end of February, although the garden might be said to be clothed, it was truly a winter garden after all. She therefore resolved to use every endeavour to find out something that would give the beds a summer dress even in the bleakest season. Having discovered what she considered a suitable subject, and for which in the meantime I fear we can find no substitute, she has, by careful cultivation and judicious selection, brought her place to such perfection as has lately received the commendations of the best authorities.

I left much pleased with all that I had seen, and impressed more forcibly than before with the truths of the preacher and the poet, that "We live but to learn," and "gather as we go."—JAMES RAE.

#### GLAZING WITHOUT PUTTY.

HAD Mr. Poynter used narrow strips of india-rubber the whole length of the rafter beneath the glass, and four screws with india-rubber collars to fasten each square to the rafter, he would not have found glazing without putty so difficult nor so ineffectual; and had he run a groove in the centre of each rafter between the squares of glass, he would not have found any ill-effects arising from rain.—WILLIAM McLELLAN, *Wemyss Castle, Fife*.

#### PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

*EPIDENDRUM DICHRUM* var. *AMABILE* (Beautiful Two-coloured Epidendrum).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Found on branches of shrubs near rivers in Bahia. Imported by Messrs. Low & Co., Clapton Nursery. Flowers rose-coloured, but liable to vary to white.—(*Bot. Mag.*, t. 5491.)

*MORENIA FRAGRANS* (Fragrant Morenia).—*Nat. ord.*, Palmae. *Linn.*, Dioecia Hexandria. A small Palm, native of Peru, Columbia, and elsewhere in South America.—(*Ibid.*, t. 5492.)

*AGAVE SAUNDERSII* (Mr. Saunders's Agave).—*Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia. Probably a native of Mexico. Flowers yellowish green.—(*Ibid.*, t. 5493.)

*CELOGYNE FUSCESCENS* var. *BRUNNEA* (Reddish-brown *Ceogyne*).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Moulmein. Re-introduced by Messrs. Low & Co. "It flowers in the winter months, and continues in beauty for several weeks. It is amongst the best of the *Ceologynes*."—(*Ibid.*, t. 5494.)

*MANETTIA MICANS* (Showy *Manettia*).—*Nat. ord.*, Rubiaceæ. *Linn.*, Tetrandria Monogynia. Messrs. Veitch and Son, King's Road, Chelsea, have it from their collector in South America, Mr. Pearce, who found it at Muna, at an elevation of 3000 to 4000 feet. Stove climber; flowers orange red.—(*Ibid.*, t. 5495.)

*ARISEMA PAPILLOSUM* (Pappilose *Arisema*).—*Nat. ord.*, Aroideæ. *Linn.*, Monœcia Monandria. Native of the Nilgherry Mountains, and of central Ceylon, at an elevation of 4000 to 6000 feet. "The large tuberous roots are used as a medicine by the Cingalese, and sometimes called 'Snake-root.'"—(*Ibid.*, t. 5496.)

ROSE—*Bernard Palissy*. Raised by M. Margottin, Bourglareine, near Paris. Colour reddish carmine, habit excellent.—(*Floral Mag.*, pl. 229.)

PETUNIAS.—*Jubilee*, rosy-lilac, barred and veined with dark maroon. Charming, white with purplish maroon bars and veins. Raised by Mr. Bull, Chelsea.—(*Ibid.*, pl. 230.)

AZALEA—*Fascination*. Raised by Mr. Ivery, Dorking, and

has won a first-class certificate from the Royal Botanic Society. The female parent was *A. tricolor*, and the male *A. Criterion*. Colour light rose, irregularly banded at the edge with white; upper petals spotted in the centre with crimson.—(*Ibid.*, pl. 231.)

**FUCHSIAS.**—*Lucretia Borgia*, raised by E. Banks, Esq., Sholden. Sepals crimson, well reflexed; petals purple, blotched with red. The Floral Committee of the Royal Horticultural Society gave it a certificate. *Fantastic*, raised by Mr. G. Smith. Sepals crimson, reflexed; petals, lavender purple, instead of being pendant spread nearly horizontally, and beneath them a second corolla with petals pendant as usual.—(*Ibid.*, pl. 232.)

**VERBENA.**—*Annie*. Raised by Mr. Cooling, of Bath, and awarded a first-class certificate by the Floral Committee of the Royal Horticultural Society. "In our opinion it is the best striped Verbena we have yet obtained, the habit being healthy, the trusses both abundant and good, and the colour pleasing and attractive. It is a bluish white at the margin with a broad wedge-shaped stripe of carmine in the centre of each segment. The marking is, in fact, analogous to that of *Striata perfecta*, only in a different colour."—(*Florist and Pomologist*, iv., 17.)

### ROSE CELINE FORESTIER.

THERE is at page 110 of your Journal this question—"Have any of your readers experienced this result with regard to that excellent yellow Rose Celine Forestier—when grown on a wall it will not flower, or at any rate will flower very sparingly?" Yes; I have experienced that result. The cure is to root-prune in place, or remove and root-prune. I removed mine and root-pruned, and the trees have ever since flowered well. It must never be cut hard at the head if removed; after re-establishment merely cut to a good eye at the top of the matured shoots. It and *Mdlle. Aristide* require less cutting than other Tea Noisettes. None of them want much cutting. Celine Forestier will flower well also, if, planted in a circular bed, it is twisted like a snake and pegged down.—W. F. RADCLIFFE, *Tarrant Rush-ton, Blandford.*

### NOTES FROM THE SHORES OF THE MEDITERRANEAN.

As one of your oldest correspondents at home I now venture to convert myself into your foreign correspondent, and as chance has afforded me an opportunity of visiting in this and the following month many gardens and markets in ports of the Mediterranean, I will send for the amusement of your readers a few notes on the flowers, fruits, and vegetables seen at each place.

We arrived at Gibraltar on the 28th of January, and on landing took a stroll into the Alameda or public garden. We were delighted to find a most beautiful display of flowers growing most luxuriantly without any attempt being made at effect by bedding out. Scarlet Geraniums, 3 or 4 feet high, were growing as permanent plants amongst Aloes, many of them displaying their graceful flower-stems with buds; the Almond tree flowers were just opening, and *Tritonia aurea* appeared to be quite at home and to have spread freely amongst the other plants. A lilac-coloured trailing *Fumaria* (?) was also very showy; the Prickly Pears were at rest; whilst the yellow *Cytisus* and abundance of a small white Jonquil, with a most disagreeable scent, formed a pleasing contrast to the Scarlet Geraniums, mixed with the tropical foliage of the Palm trees. We were pleased to notice that several new plants had recently been put in—*Cupressus Lambertiana*, and, we thought, *Wellingtonia gigantea*, with several plants of, what we thought to be, the Castor-Oil tree, but which, whatever tropical plant it was, appeared to require protection. We did not notice amongst the wild plants and weeds any thing that could not be found at home.

We visited the market at 7 A.M., and found a most lively scene, the place being crowded with Moors in their characteristic dress, and Spanish peasantry with their decorated mules and asses laden with vegetables, fruit, and poultry. The stalls were well filled with Oranges, both common and

the small Tangiers; Lemons very fine; but not any Limes nor Grapes. Shaddocks were small, Walnuts large, other Nuts small and poor. Sugar-Cane was also on sale, but poor and unripe. The vegetables were very good and abundant—splendid Broccoli, large Lettuces, Radishes very large, but exceedingly tender and well grown, Endives well blanched, fine-sized fresh-grown Carrots, Turnips, Parsnips, Onions, and Leeks. There were some Peas, but with small and ill-filled pods, and a few handfuls of poor Asparagus. Of dried fruits Figs in various ways, Cherries, Chestnuts without husks and peel, were offered in casks for cooking purposes; also Olives green and black, and we need hardly say that Garlic was also there in abundance. We must not forget to mention the Yams, of which there were two varieties, and new Potatoes of a fair size. Jerusalem Artichokes were abundant, but very poor in quality. The cut flowers were the Roses, Stocks, Geraniums, Heliotropes, and abundance of the single Roman Narcissus.

We took a peep at the poultry, but searched in vain for the well-known white-faced Spanish fowl. Strange to say we could not find the smallest trace of that breed; but the birds appeared to be fair ordinary cross-breeds, evidently with a strong cross of the plump, round top-knotted Polish form. Hares, snipe, and quail were the only game on sale; and amongst the butchers' stalls kid appeared the only novelty.

The fish on sale were small and poor, but some of them of queer unknown forms—eels, soles, red and grey mullet, bonetas, ink fish, bream, or rather a fish very like it, sardines, shrimps, and oysters.

Outside the market we found droves of she-goats, and were much amused to see them being milked at each customer's door as required; evidently a very excellent mode of securing an abundant supply of the pure article without the assistance of the iron-tailed cow, so well known at home.—CELEBS.

### COTTON SEEDS.

SINCE I last wrote I have received from Isaac Watts, Esq., Hon. Sec. to the Cotton Supply Association, six samples of the following kinds—viz., Sea Island, Orleans, Peruvian, Egyptian, Guayaquil, and Carthagea, with an intimation that I may have more if wanted. I have now in my possession as much as would serve about forty. If any more is wanted I will get it. I forgot to say in my last that the young plants should be carefully repotted, as they fill the pots with roots.—JOHN HAGUE, 36, *Mount Street, Ashton-under-Lyne.*

### GISHURST COMPOUND VERSUS SCALE.

IN continuation of your answer to "READER," in last week's Journal, perhaps I may be allowed to say, that where orchard-house or wall trees have been much infested with mussel scale we have found Gishurst to be most efficacious when applied without more water than necessary to make a thick lather with a painter's brush on the top of the cake in the box, this lather to be well painted over the stems and all parts where the scale is observed, but avoiding the buds. In November, 1863, I described in this Journal an experiment made on some old wall trees so blighted year after year as not to bear at all, that a first year's application to some of the trees had led to some fruit and a comparatively healthy appearance of the wood, and that all the trees were to be subjected to a strong Gishurst treatment, the result of which I would communicate. I may now state that, with this second year's application (eight ounces to the gallon), all the trees bore some fine fruit, some of them fair crops (trees which for at least eight years had not ripened fruit), and that the quantity of fruit-buds and healthy appearance of the wood give great promise for this year. About a month ago we washed them again with 8 ounces to the gallon, with the exception of one Pear tree which had, we believe, never been previously treated, and which was in some parts of its branches and twigs entirely coated with mussel scale, to this we have applied lather from the box as above described. With your permission I will herewith describe the result.—G. W.

## WORK FOR THE WEEK.

## KITCHEN GARDEN.

As soon as the ground becomes mellow let all the crops coming on have a thorough hoeing or surface-stirring. This is of the utmost importance at this period, but should not be done until the ground is somewhat dry. *Asparagus*, in mild weather, that in frames or pits should have abundance of air after the shoots have made their appearance. Prepare ground for permanent beds. If the soil works well, plenty of good rotten stable manure should be used in their formation. *Carrots*, a little seed of the Early Horn may now be sown on a sheltered warm border when the soil is dry and works freely. Those in frames should be thinned when an inch or two high. *Horseradish*, prepare the ground for planting, dig it two spits deep. No manure should be dug in unless the ground is very poor. *Jerusalem Artichokes* may now be planted. *Onions*, plant those bulbs of last year which begin to grow. This will be found very useful where there is a scarcity of sound ones. They may also be planted for seed. *Parsley*, a sowing should be made as soon as the ground is in a fit state to receive the seed. *Peas*, make a sowing of Knight's Dwarf Marrow; at the same time, to keep up a succession, two or three crops must be sown of those sorts which come in for use quickly, to be ready before the Marrows. *Potatoes*, plant some on a warm sheltered border if the weather is mild and favourable. *Spinach*, a few rows may be sown between the early Peas, if there is a scarcity of the autumn-sown.

## FRUIT GARDEN.

Clear away the dead leaves from Strawberry plants, and remove superfluous runners from the Alpine Strawberry. All should not be removed, as the runners generally bear better than the old plants. Look to the Fig trees, prune and train those that require it, tying and bending the strong shoots down, which will induce them to push out a number of very short-jointed bearing shoots.

## FLOWER GARDEN.

Well-grown annuals contribute much to the gaiety of the garden; and although not quite so well adapted for masses as some of our half-hardy plants, they are very eligible for borders and mixed beds. They are frequently treated with too much kindness, sown in soil of too rich a character, and, of course, run too much to leaf. We would advise all those who have the means to devote two little frames to their especial cultivation at this period, the one with bottom heat, the other without it. That with bottom heat would be better with a plunging material possessing a heat of 70°, the pots placed close to the clear glass roof, and matted up at night. The other frame, without bottom heat, should be raised about a foot above the ground level, where water cannot possibly stand, and should be filled to within a foot of the glass with cinder ashes. They should both be well watered with boiling water to destroy all insects previous to placing the pots. The tender and half-hardy kinds must be raised in the frame with heat, managing the sowings so as to afford a succession according to the period at which they are required to bloom. The hardy kinds, however, will have to be removed to the cold frame as soon as an inch high; they would then harden off in a couple of weeks, and be ready for turning out in the borders. The tender annuals, if drawing in the warm frame, might be removed to warm and light shelves in the greenhouse or other structures. The soil for hardy annuals should be chiefly plain loam; this will be found to produce sturdier plants than rich vegetable matters, and much blossom in proportion to the amount of foliage. As soon as the frost is out of ground, and the surface in a fit state to rake, the beds for planting *Ranunculuses* must be brought to a perfect level. It is a very important object to insure success in the cultivation of this flower that the roots be placed no deeper than 1½ inch. Should they be either deeper or more shallow a new and smaller root is formed at this depth, to the serious injury of the plant. The distance between the rows should be 6 inches. A little rockwork, made to hide unsightly objects or to harmonise with others, may be introduced with advantage in many places, and planted with many of the common hardy plants, such as Wallflowers, Indian Pinks, *Aubrieta purpurea*, *Alyssum saxatile*, *Cerastium tomentosum*, Ferns, *Fragarias*, *Geum coccineum*—some to be disposed in the

recesses, and others in the more prominent parts according to their natural habits of growing in sunshine or shade.

## GREENHOUSE AND CONSERVATORY.

Scarlet and other *Pelargoniums* that were taken up from the beds in the autumn to be placed in heat to start them into growth. *Acacia*, *Mimosa*, *Gnidia*, *Diosma*, *Boronia*, *Pultenæa*, *Epacris*, and other such plants should be regularly examined to clear them of all dirt, to scrape off any moss, &c., that may have grown on the surface of the mould, and to surface them with a little fresh soil; and any plants that have grown with a loose habit to be tied up. In severe weather, such as we are experiencing, when it is absolutely necessary to keep fires both day and night, the soil in the pots near the pipes or flues is soon dried up, and frequent waterings are necessary; the water to be kept in the house during the night, and given to the plants in the morning. Be careful not to let things in bloom suffer for want of water, giving weak liquid manure to *Salvias*, *Camellias*, &c., and use every means to preserve the beauty of specimens in bloom as long as possible. Let all the plants be tied with the least possible delay; for it is difficult to tie a plant so as not to look somewhat stiff, formal, and therefore unnatural, and the sooner all this description of work is done the better specimens will look when in bloom late in the season. No time should be lost in arranging, cleaning, and pruning the plants occupying the borders of the conservatory. When the health, or habit, or other considerations, render it desirable that the season of blooming should be retarded, pruning may be performed later. Pot *Verbenas* to supply cuttings; *Heliotropes* may also be placed in heat for the same purpose. *Fuchsias* should be set to work, and cuttings obtained as soon as the shoots are sufficiently forward.

## STOVE.

Increase atmospheric moisture in proportion to heat and light. Look sharp after insects; the snails are very fond of the young buds of *Orchids*, at this period undergoing a sort of malting process. Some early *Achimenes*, *Gloxinias*, &c., must be set to work. Some of the *Ipomœas*, *Echites*, *Pergularias*, the *Stephanotis*, &c., may be trimmed in, disrooted if necessary, and plunged in a moderate bottom heat, using but little water until root-action commences. Some of the *Echites* are easily rooted in this way, and will endure a vast amount of drought. A small hotbed, as advised last week, is most useful to receive fresh-potted plants and to excite others into growth from which it is desirable to obtain cuttings; it is also a very suitable place for striking cuttings of *Verbenas*, &c.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

OUT of doors did nothing but trench and turn over ridged-up ground, so as to sweeten it by exposure to the frost, the best of all pulverisers of stiff soil. The rougher this turning over ridges the better, in order that the frosty air may have more surface on which to act, and thus far we agree with our observing correspondent, "WYESIDE," page 111. But in trenching and ridging-up very stiff clayey soil for the first time, we would, on the other hand, not care about leaving it so rough when frost was expected. In these circumstances we have admired first-rate workmen, as we used to feel a pride in doing in our younger days, turning in the top spit in small spadefulls, or breaking it if in large ones, and then placing the last and deepest spit as high and angular-ridged as possible, both sides of the ridge shining in the sun with the spade marks, and no attempt made to pulverise or remove these. On these shining, smooth, compact spadefuls or lumps, the frost exercised a penetrating and crumbling power, which it could not have done if they had been left in smaller, detached, and broken-up pieces. Just so in the case of other materials, the more solid and compact any body is left, the more in general will it be influenced by heat or by cold.

Over and over again, we have noticed the same thing in stiff land ploughed up early, and left to be acted on by the frosts of winter. In many such cases the frost proved a more efficient pulveriser than all the improved cultivators, and clod-crushers. The whole matter wants ventilation,

However, as many mistakes are made from thinking that merely opening the surface of the soil to air, is synonymous with letting the heat of the summer in. The very reverse is the case, as we have proved over and over again by thermometers placed in the soil, the soil beneath a hard gravel walk being warmer in summer than similar soil at similar depths under soil nicely pulverised and turned at the surface. Of course, in winter, the circumstances were reversed. When we surface-stir, and fork over borders in summer, we would like it to be clearly understood, that it is done for other purposes than giving an increased temperature to the border, as that, and watering, too, unless with heated water, will lower the temperature. We must thus often lower the temperature, even when we wish to raise it.

Partly on this account we would wish to direct prominent attention to the article of Mr. Fowler, page 125, on the aëration of borders. It will be observed that he increases the heat of the border by letting the warm air of the day circulate through it and beneath it, not by breaking up the surface. Were we in a position to do new work, we certainly would keep such an article in mind. It may, perhaps, be recollected that the most wonderful produce of the Barossa Grape, at the Under-Secretary's in the Phoenix Park, Dublin, was from a Vine growing in a border aërated very much as Mr. Fowler describes.

With regard to the last sentence of the Editors' answer to "WYBESIDE," page 111, beginning thus—"Consolidating the earth over the roots of fruit trees is one of the most fatal of practices," with all due respect we have a suspicion that there are two sides to the question here. We have seen Apricots gathered from trees (and the whole of the space in which the roots grew was either paved, pitched over, or hard-gravelled over), such as we have never seen beaten from a border with its surface nicely loosened. There generally was a space of 18 or 24 inches square left exposed at the bole of the tree, on which a pail of soapsuds could be poured in summer; but even without that we have known such trees produce heavily for many years, when all they could obtain in the way of humidity must have chiefly been from absorbing the moisture from the surrounding soil, rather than that from the soil in which the roots were placed. Similar circumstances have been related by Mr. Beaton and others, and we think also by ourselves. We presume the great fruitfulness in such cases was owing to the thorough perfecting of the wood, and the greater heat that the ground obtained from the solid compact surface over the roots. Such facts, which may often be noticed, have led us to the conclusion that, in the case of some hardy but rather tender fruits which seldom do well in cold situations, they should have a trial by planting and training them thinly on a bank sloping to the south, the surface of the bank being made firm by concreting or tarring, and merely openings left in the soil for giving water when deemed necessary. If the borders should be aërated according to Mr. Fowler's plan so much the better, but we anticipate great results alike from the absorption, conduction, and reflection of heat. Would some of our young experimentalists give the matter a fair trial? Many are trying their success with Mr. Rivera's curate's vinery. When once the Vines are established let it be tried what flagging or concreting the surface would do, instead of the slates, which, if loose, keep the heat from the ground. Of course holes could be left for watering. We shall have some faith in firm surfaces absorbing, conducting, and reflecting heat, until the whole idea has been proved wrong, and we make a present of it to our young friends to try and experimentalise on a small scale, and then report results. Right or wrong, we have grounded many of our practical advices on such observed facts, such as counselling the firm packing of soil in pots for fruiting plants, and the attempt at least to establish the axioms "If you wish plants to grow freely, keep the soil open; if you wish them to flower or fruit freely, keep the soil firm." At the same time no theory should be ridden too hard, and there are plenty of hardy orchard trees to which the remarks of our Editors too thoroughly apply; but we have been alluding to fruit plants rather too tender for our northern climate, and where sun heat must be made the most of as an element of success.

*Dwarf Kidney Beans.*—Potted-off a lot, and sowed more where there was a little heat for them. After this season every hole and corner under glass will be crammed, and the

contest will be between the useful and the ornamental. The above mode of transplanting is chiefly to be commended for saving room, otherwise it would be less trouble and labour to sow at once in pots or in beds, where they were designed to perfect their produce. Wherever the cramming system under glass has to be resorted to, making the most of space is always attended with much additional labour. For instance: these moveable boxes of Beans may be sown anywhere under shelves or stages, where there is a heat approaching 60°. As soon as the Beans are up they must be placed in a position where there is light, to prevent them being drawn; and as soon as the stem appears—that is, when three leaves appear above the seed leaves—the plants should be turned into pots, say at this season five plants into an eight-inch pot, using rich light soil that has previously been warmed. These pots may also stand close together until the plants begin to incommode each other, when they must be thinned to perfect their produce; most room being needed just when the plants are in bloom. By this means much room is saved until the plants approach their full growth, but the labour is much increased. Just think of the difference between sowing at once in pots and in a bed of earth, and doing nothing more except watering and a little syringing until the crop is gathered; but then, thus to save labour, much space and heating under glass are required. We have several times grown them economically in a pit of six lights by sowing at once in the soil. The six lights made three successions—sown at intervals of three weeks. The seeds were placed in rows 2 feet apart, and when well above ground were earthed up, so as to leave a trench between them. When the first two lights came into a bearing state, and had produced a little, seeds were sown in the trench, and by the time they were up and needed more room the first crop was removed, and so on with the second and third division, adding a little leaf mould to the second and third-crop sowing in the trench, before earthing up with the soil in which the first crop grew. We have had four successions in the same place by using manure water and a little fresh soil to every crop. Thus in six lights we have had from nine to twelve successions. It required a little calculation to make sure of the succession crop being up and needing more room as the first crop was becoming exhausted. Sometimes, to continue the bearing as long as possible and yet to give room to the succession crop, we have pruned the wasted parts, cut off the older leaves, or run a string along each side of the rows to confine them until the fruit was obtained.

This successional plan we found more profitable than any doctoring of the old plants, so as to keep them on in a bearing state. After May and June, if well treated with rich soil and manure waterings, and closely picked, the same plants will produce until frost destroy them; but earlier, and kept constantly under glass, the plants do not produce alike continuously and profitably. Growing such in pits is generally better than placing them in forcing-houses, especially after April, as after that time, if there is a thrips about the place it will find its way to the Kidney Beans. In fact, it is no bad plan to place a few plants in a vinery or Peach-house as a sort of bait; for if no thrips appear on a Kidney Bean you may rest pretty certain that you have none in the house. If they do appear the Beans should be taken out, carrying the plant out as carefully as possible, so that not a single insect should be shaken off. Whether in pits or houses, syringing with clear soot water is a good thing for keeping them clean. When they do become infested, the washing and smoking that would be necessary to clean them would cost as much as the produce would be worth. The most economical plan would be to take the bulk of the produce, clean the place, lime and sulphur-wash all the walls and woodwork, and smoke with a little burning sulphur, taking care that the fumes have access to nothing that has life, or if the plants should be deciduous, that the buds are dormant and the wood well ripened.

We are thus particular as to these Beans, as we believe that when grown under glass the produce has a sweetness and tenderness peculiarly their own. There is little difference in the dwarf kinds, but in general those that produce clean, not mottled, pods are the most liked, though some of the latter are equally juicy and sweet. The small Newington, when the pods are gathered about 2 inches or

rather less in length, are very nice when cooked whole. The flavour of the Bean is thus better secured than when the pods are cut up or whittled into little morsels. These and other vegetables are often sadly spoiled. The last time we sat at a public dinner party the sight of the vegetables was more than enough. What had been good Beans looked as if they had been sweltering for a fortnight in the sun on the top of a rubbish-heap. Soft boiling water and a little dash of carbonate of soda, with even common attention, would have made all the difference between the enticing and the revolting.

Other matters in the kitchen garden and fruit garden much the same as in previous weeks, as the frost has prevented much being done. In the orchard-house, proceeded with painting the trees and whitewashing the wall, or rather, thinly covering it, the wash being fresh lime dulled with blueblack, and a good portion of flowers of sulphur. We have not washed the wall much after syringing well with the warm water, and will, therefore, put on the finishing wash of lime and sulphur rather thin, so as to fill up any holes that may be left. Last season, in July, we found a trace of spider, and on washing open parts of the wall with sulphur and soft soap water, we soon got rid of them by shutting up early when the sun was in the house.

#### ORNAMENTAL DEPARTMENT.

Went on potting, &c., as in previous weeks. The frost being sharp, protection gave us but little trouble, as we allowed it to remain night and day, except in the case of Cucumbers, Potatoes, Strawberries, &c., in heat. In such dull frosty weather, this gives a great relief where much is done in the way of covering and protection. Having nothing very particular to record, we would give a few words to our friends, the window gardeners, taking a number of matters in a random way.

*Old Scarlet Geraniums Rotting.*—"ALPHA" says she crammed some boxes in the faggot-style as we recommended, and put them in a spare room without fire, watered them at Christmas, and what with frost and damp they are rotting." Very sorry; such plants should have been packed firmly in soil, either dampish, or made so by watering, and then covered on the surface with an inch or two of dry soil. When frost set in, the plants and the box should have been covered either with cloths or a little dry hay. Watering should have been let alone until the plants began to break. In a cold place we are satisfied if they thus break in March—that will be time enough.

*Scarlet Geraniums for the Window.*—No plan tried beats Mr. Beaton's Harry Moore's. Supposing the box to be filled for 1865:—Let the plants become rather dry after September, pick off the leaves before the end of October, and take the boxes to a spare room, or garret, before the plants are touched with frost; protect them from frost when it comes; uncover, and keep near the light in fine weather. In March, as they break, prune away any dead points and irregular bits, and give a little water, not by drenching the box, but by making little holes with a pointed stick about 6 inches apart, and filling these with water in the first place. By the time the new leaves are as large as a shilling, scrape off a lot of the surface soil, stir up the rest a little, water with water about 60° if needed, then top dress with fibry loam and old cowdung, or any other rotten manure, and water afterwards as needed, keeping the boxes inside until the 20th of May. The less the plants have grown before that time, provided they are healthy, the more abundantly will they bloom, and the better will the wood be ripened for another year. We see no reason why a Geranium-box should not thus continue with the same plants, and never removing them, to go on blooming every summer for the space of twenty or even thirty years. Such plants are much easier kept in winter than those with luxuriant growth taken up out of flower-beds, the free-blooming and little growing of such plants in pots and boxes, are what enabled them to be so easily kept in a garret, spare room, or dry cellar. We have known such boxes placed in a hay-loft, a little hay shaken over them in December, and remaining untouched until March, when the young buds were breaking, and then they were allowed some light in fine days. They will thrive all the better if few of the largest leaves are not more than the size of a florin when placed outside the window in May.

*Fuchsias Dropping their Flowers.*—"OMEGA" tells us that her Fuchsias all dropped their bloom inside of the window

last summer. This was owing either to want of air or want of water; most likely they would have done as well outside the window for a time. We have known Fuchsias drop their flowers and seem damp enough, and even the pot when struck emitted a heavy sound, and yet, except at the outsides of the balls, such plants were dry. When holes were made in the centre of the ball with a pointed stick, and then watered, or the pot was submerged in a pail of water for ten minutes, the blooms opened and kept on well enough. The plants had either been shifted when the roots were dry, or the fresh soil added had been left rather loose, and the water applied escaped by the loose soil.

*Repotting.*—A great many window gardeners lose their plants, or render them unhealthy, by shifting them with the soil of the old plants dry. It is next to impossible ever to make the old ball and the new soil fraternise in such circumstances, and the water given is repelled from the old ball as by a duck's wing. Hence, in potting, the importance at this season of adopting one of two methods.

First. Here is a nice Geranium or Pelargonium in a four-inch pot, the roots filling the pot nicely. Well, as it is desirable to grow it on with little check, the pot is well watered some hours before shifting, the outside ball is gently ruffled, and the roots disengaged before the ball is transferred to aerated heated soil in a six-inch pot, the soil being packed rather firm. In such a case, if the soil is rather moist, no water will be required for a time, except where the old ball and the new soil touch each other.

Secondly. Here is a little Fuchsia in a small pot growing slowly all the winter, and the pot now full of roots. Well, treat it in the same manner; but

Thirdly. Here is a large Fuchsia in a large pot. We have pruned it a little, and we are more anxious that the plant should be a mass of bloom, than that it should become more luxuriant, or larger than usual. Well, we shall suppose that the pot is standing on the damp floor of a cellar, in which case it would need no water all the winter. If it stood in a dry garret, it might need a little, unless it was plunged in some damp material. Now, if the plant is pretty vigorous, it may thrive well in a window for several years, if top dressed like the boxes of Geraniums. If becoming a little weakly, it is best to give it fresh soil in the same space of feeding-room—that is, in the same pot, or the same sized pot. To secure dampness of the roots in this case, the best plan is to shake the most of the dry earth away, dip the roots for ten minutes in water at 60°, let them drain a little, and repot in rich light loam, pretty well consolidated. By this plan little water will be needed until the plant is growing away freely, and providing the fresh soil is just moist, the fresh roots will run into it all the more kindly from not being deluged with water.

Let us here repeat, that next to cleanliness, nicely aerated warm soil for spring-shifting is a matter of great importance.

*Bulbs* now showing for bloom, and in bloom, should have all the light possible, and when dry will relish a little clear manure water. Hyacinths in glasses will be benefited by two or three bits of charcoal in the glasses; but for the sake of observing the rooting process, there is no great pleasure in seeing these glasses in rooms, though they are more elegant than the general run of pots. The best plan is to grow them in pots, and keep these out of sight, by plunging or planting in an elegant vase or basket. Flowering plants may be transferred from pots to glasses, by holding the ball from a pot in your hands in a pail of water, washing away the earth, and then placing the roots in the glasses. When in bloom, or nearly so, such plants may be moved to the middle of the room, or even the mantelpiece on a cold frosty night, but during the day they should have all the light possible. Some time ago we saw in a fine day what ought to have been a noble row of Hyacinths on the mantel-shelf of the sitting-room. It was something like transferring the worthy owners to the black hole of Calcutta.—R. F.

#### TRADE CATALOGUES RECEIVED.

Lamoureux, Clark, & Co., Plymouth.—General Price Current and Garden Directory.

William Davidson, 30A, St. Andrew Square, Edinburgh.—Select List of Seeds, Plants, and Implements.

John Salter, Versailles Nursery, William Street, Hammersmith.—Catalogue of *Chrysanthemums, Dahlias, Pæonies, Phloxes, Variegated Plants, &c.*

E. G. Henderson & Son, Wellington Road, St. John's Wood, London.—Catalogue of *Flower, Vegetable, and Agricultural Seeds.*

COVENT GARDEN MARKET.—FEBRUARY 18.

The supply of out-door produce is very short in consequence of the severe weather. Pines continue scarce; hothouse Grapes are more than sufficient for the demand. The usual continental supplies are well kept up, and include some very good Cabbage Lettuces. Savoys, Brussels Sprouts, &c., are not over-plentiful, and have advanced considerably in price. New Potatoes are bringing from 4d. to 1s. per pound; of others there is still a good supply.

TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

EARLY KING POTATO.—It has been in my possession two years. It is not strictly a round Potato, as "E. W." terms it, as both round and kidney shaped tubers are frequently to be found attached to the same plant. It is not a first early, but a good second early on our light soil. It is a very handsome Potato, an excellent cropper, and has a smooth yellow skin with very few eyes. For exhibition purposes I know of no round Potato to match it, but it requires a good breadth to pick from for the reason stated above. It is a very good flavour and keeps well. Should your correspondent feel disposed to forward his address to me, on receipt of it I shall be happy to forward him a few sets.—THOMAS LOCKIE, Culham, Oxford.

COTTAGE GARDENERS' DICTIONARY (H. W.).—That published by H. G. Bohn is the same as that published previously by Kent & Co. You are quite wrong in thinking the writer your name not "practical," for he is a head gardener at a good establishment. The others you mention still write for us though, for private reasons, they assume fictitious names; and many able men besides, whose names have never appeared, aid us by their contributions and in answering questions.

BOUGAINVILLEA, &c. (K. S.).—Bougainvillea speciosa is identical with B. spectabilis, a native of Peru and other parts of South America. Lomaria gibba is a very handsome greenhouse Fern from New Caledonia, with stout, erect, arborescent caudex, and plummy light green fronds, 2 feet long, divided into linear, acute, undulated segments, which are gibbously decurrent at the base; the fertile fronds with linear segments.

BOOKS (H. R.).—There are two supplements to London's "Encyclopædia of Plants," the last was published in 1855. Messrs Longman will tell you about price, and whether they can be supplied. There is no recent edition of either Paxton's "Botanical Dictionary" or of the "Cottage Gardeners' Dictionary."

REMOVING THE DEAD FRONDS OF HARDY FERNS (A Subscriber).—The decayed fronds are better not removed in winter, for they act to the crowns as a protection from frost. Such protection from severe weather is advantageous to the more delicate kinds; but for the common kinds it does not much matter whether the fronds are removed or not.

CONCRETE WALKS (A Constant Subscriber).—A layer of stones, bricks, bats, shells, or clinkers, 6 inches deep, to form a dry bottom; a layer of chalk or lime, in the proportion of one to ten of the stones or other foundation, and well rolled and watered, to the thickness of 3 inches, with a rise of 2 inches in the centre; over this half an inch of gravel and lime, or fine chalk; water and roll well again; add one-eighth of an inch of the best coloured gravel, and again roll until quite solid. Have the walk 2 inches wider on each side than you desire, as this checks the turf and weeds from encroaching, and prevents the rain water getting to the foundation of the walk. We do not know what book you refer to.

TRANSPLANTING ROSES (Three-years' Subscriber).—You may remove Roses planted last November from now until the beginning of May. Take them up carefully and wrap the roots in damp moss or hay. Plant as soon after removal as practicable, watering well afterwards. If not removed before the shoots have made some growth, it would be well to wrap the stems and also the roots and heads in damp hay, not too much, but a little to keep them fresh. Water copiously after planting, daily or every other day at the roots, and sprinze the heads night and morning, shading from bright sun for a few hours in the middle of the day until the plants become established. In this way you will be enabled to remove the Roses; but they will not do so well this summer as if they were not removed.

KEEPING VERBENAS THROUGH THE WINTER (Verbena).—The best way of keeping Verbenas over the winter is to insert the cuttings in pots or pans and not too close together, in the last week in August or the beginning of September, in order that they may be struck before dull damp weather sets in. Keep them in the same pots or pans over the winter, placing them on a shelf near the glass in a cool, dry, airy part of any structure from which frost is just excluded. To pot or prick them off in autumn is unnecessary, as it wastes room, and many are killed in consequence of the waterings necessary to keep them from flagging. We have them, fifty or more in 12-inch pans, any cutting in which will now furnish half a dozen cuttings, which we will put in soon in gentle heat to strike, for we find an early spring-struck cutting every way better than one inserted in autumn and potbound. In winter they should have no more water than is necessary to keep them alive. Verbenas and Lobelias are rather more tender than Calceolarias, the latter bearing more moisture than Verbenas. We think your want of success is due to keeping them too damp, both as regards the atmosphere and their roots, the transplanting into boxes contributing to the evil as much as anything. We have the same ideas as yourself respecting the preservation of Verbenas in a cold frame during winter, much in the same manner as Calceolarias, but damp is their greatest enemy, and how to get rid of this in a cold frame is a question difficult to answer, especially when they are shut up (as our Calceolarias have been for the last three weeks), without once removing the covering.

TRIMMING HOLLY HEDGE—SEEDS OF SALVIA NEMOROSA AND MELILOTUS LUCANTHA (A. S. A.).—The most suitable time to cut back a Holly hedge is from the 1st to the 29th of May, and the very best time is just before the new growths are made. The shoots come as freely from the old as from the young wood, and an old thin tree will become very ornamental by cutting it well back. We have perfect cones of several of the variegated kinds that but a short time ago were not fit to be seen, but with cutting well in they are after a year's growth perfect pictures. Any one having an old thin hedge, or a spare ugly tree, will do well to cut it to the desired shape during May, and by the autumn of the same year they will find it transformed into an ornamental object. We do not know where Salvia nemorosa is to be obtained. It is a most ornamental herbaceous plant, and forms a lovely bed of pale purple, its innumerable blossoms being borne in the greatest profusion from May to the end of September, and its silvery foliage being as bright as many ribbon plants. It is remarkable that, being of such value for decorative purposes, it should not find its way into our lists of herbaceous plants. Seeds of Melilotus lucantha can be obtained from Messrs Sutton of Reading, and doubtless many other seedsmen. Of all the plants in a garden there is none which the bees visit more than Salvia nemorosa.

PRUNING CLIMBING ROSES—SOIL FOR ROSES (C. Bond).—In pruning the majority of climbing Roses the aim should be to thin-out the old shoots, and lay in the previous year's well-ripened wood, leaving the shoots at some length; for if cut close they will only make wood instead of flowering. Instead of pruning them to so many eyes, as in the case of standard Roses, merely thin-out the old wood, and take off a few inches of their points. All foreright wood and the shoots that tend to cause irregularity should be cut clean out; but the less a climbing Rose is pruned the more abundant will be the bloom. Roses for early blooming should be pruned in February. The old saying, that a Rose will grow well wherever a Cabbage does is to a certain extent correct, for they both flourish in a rich soil. They like a deep, rich, and rather strong loam, but if you manure your soil liberally with half-rotten cowdung, or other not very stimulating manure, Roses do very fairly on gravelly soils, having the plants on their own roots, or on the Manetti stock budded low. On light gravelly soils the plants on the Dog Rose are short-lived, and never vigorous. All Roses should be planted on ground well manured, and be kept mulched with short manure.

SAPONARIAS—NEMESIA COMPACTA (An Amateur).—The Saponaria calabrica alba, in our opinion, is not equal to the pink calabrica; the white is dingy, in-lead of clear. Instead of making alternate little beds or rings of the two Saponarias, we would advise alternating the pink Saponaria with Nemophila insignis, the white and blue of which would contrast well with the pink. The Nemesia compacta is a pretty little thing, with various colours. It should be raised in a little heat, and planted out about the end of May. They are mostly low-growing, a few inches in height. Alba has white flowers, insignis blue, and La Superbe rose; and compacta has often all these colours.

RENEWING VINE-BORDER—VINES IN POTS (An Amateur).—You seem to have done quite right with your VINES. It strikes us the roots had become too dry, which might be a cause of the Grapes shanking. This would also induce the roots to run down among the drainage in search of moisture. Be this as it may, you have done quite right. Protect your border from this frost. The easiest plan for fruiting your Vines in pots would be to set them in your vinery, top-dress the pots with rich manure, as old cowdung, and let them break gradually. If you wish to force them, they will be much benefited by plunging the pots in a mild bottom heat, beginning at 55°, and gradually increasing the temperature in five or six weeks to 80°. Begin with top heat at 45°, gradually increasing it to 65° and 70°, with a rise of 10° from sunshine.

**INK FOR ZINC LABELS (A Gardener).**—Besides that to which you refer we have been told that the following is very superior. We have never tried it, and shall be obliged by any one who has used it informing us if it is a good and permanent ink for such labels. Two drachms nitric acid, half an ounce sulphate of copper, half a pint of water, mix; brighten the zinc with fine sand paper, and write with a clean quill pen.

**EUCHARIS AMAZONICA CULTURE (Fairfield).**—The *Eucharis amazonica*—the *E. grandiflora* of botanists—is a thick-leaved, evergreen, bulbous Amaryllid from Granada, which will stand, like many other Amaryllids, rather rough treatment, provided it has an extra start in growth, in a somewhat high temperature, in the spring. A common stove would then suit, if the temperature were not too high; and if a little bottom heat can be given at that time all the better. Thus, say from the middle of March to the middle of June, a bottom heat of from 75° to 80°, and a top heat in the house of from 65° to 70°. About the middle of June raise the pot out of the bed by degrees. In a few days remove the plant to a colder and more airy part of the stove, and then, in a few days, remove it to a greenhouse, where it will have all the sun heat possible, and water required, until September. Then diminish water, to hasten the hardening process, and, by the end of the month, remove again to a cool stove, where the temperature would range from 50° to 55°; and, of course, during the winter, at that temperature, little water would be required, but enough to keep the plant healthy and green. As soon as you think proper to excite the plant, give it, as above stated, a higher temperature, and a moist sweet bottom heat, though it will do without it. Fibry loam and a little peat will suit it, and manure water, or rich top-dressing, may be used when making fresh growth.

**ARRANGEMENT OF FLOWERS (Amateur).**—We think your proposed arrangement will look very nice—that is, *Perilla*, *Christine Geranium*, *Aurea floribunda Calceolaria*, and *Verbena venosa* or *Lobelia speciosa*; but you will have to peg the *Verbena* to keep it low enough. As to the ideas of mixing, and to *Punch Geranium* being preferable to *Perilla*, we agree with you. The following would make a beautiful border:—*Punch* for background, or two plants of *Punch* and one of white *Feverfew*; second row, *Christine* and *Verbena venosa*, mixed—the *Verbena* the same height as the *Geranium*; third row, *Calceolaria*; edging, *Lobelia speciosa*. Sow the *Verbena* now in a nice hotbed, prick off and pot as soon as you can handle it, and it will be quite high enough for the *Geranium*.

**FLOWER-GARDEN PLAN (Yorkshire Amateur).**—Unless on the principle that flowers will always look well, and that you have so planted as to make each bed distinct, no plan can be uglier than that which you have adopted. Each of these pieces of lawn, even as now serpentine, and with the walk through them, would make a nice group of beds, regularly balanced, and with lawn between them, so that you could balance and contrast your colours. In previous volumes, and in the "Flower Garden Manual," you will see plans which you might easily modify to suit your place. We cannot undertake to do this, or we would never know where to stop. For instance, the middle part of plan 6, with a little modification, would just suit your largest piece of ground, giving you seven clumps; and so would a modification of plan 4. If you do nothing of the kind this season, then, certainly, we prefer the one circle in the middle to these unmeaning scattered clumps. We would even prefer a large oval to the circle, as more in unison with the shape of the ground; and then you might plant it in bands, or make a figure by the planting, in Mr. Robson's style. We do not think you want teaching as to combining or contrasting the colours. If you form a group, which we would advise, we will give you one rule, and then you cannot go far wrong: The group should be so complete in itself that one figure or clump cannot be changed without destroying the balance of the whole. In your lower beds not one has the least connection with another.

**NAMES OF PLANTS.—(W. L.).**—*Erica vagans*. (*Spring Croft*).—*Magnolia furcata*. (*A. W. C.*).—*Garrya elliptica*, a hardy shrub from Northern California. (*G. H.*).—2, *Cytisus canariensis*; 3, *C. rhodopena*; 4, *Acacia armata*; 6, *Falcatia stricta*; 7, *Pabiana imbricata*; 11, *Cyclamen persicum*. The rest cannot be named correctly without their flowers. (*J. W.*).—*Leucopogon australis*.

**POULTRY, BEE, and HOUSEHOLD CHRONICLE.**

**THE WILTSHIRE RECTOR.**

GOOD "WILTSHIRE RECTOR," a kindly soul, living well and cheerfully among his children and his pets, and his pursuits! A little time ago, I breakfasted with him (in imagination), and I pictured him to myself seated at a cheerful table, with "wife and bairns," revelling in the luxury of new-laid eggs, and "the Journal;" sitting among his boys, as Longfellow says, and finding lessons in eggs and all things. I know some oldish boys who profit by his teaching and look for it. Well, he went to see "Y. B. A. Z.," and before he went he asked himself what he was like. I, endeavouring to look like Lord Burleigh, and profoundly shaking my head, ask myself, What is "WILTSHIRE RECTOR" like? "The Journal" is well known among my circle, and I ask one of my family if he has ever imagined what the "W. R." is like? He says he met a man in the Strand exactly like him, but as he has never seen him, and cannot describe him, it does not help me at all.

I am led to this, because I said the other day to a clerical gentleman I met, "I often read your contributions to THE JOURNAL OF HORTICULTURE." "Mine!" said the good friend, "I never wrote a line for it in my life." I had long made up my mind, that I recognised his style throughout; had I seen the manuscript, I should have traced the dottings of

the i's, and the crossing of the t's. Besides, at certain passages I could imagine the writer's countenance, I had done so for months, and then to be told he was not the man, it was too bad.

Then, who is he, and what is he like? It tormented me. As the snow was falling fast, and I could not get out, I leaned back in my chair to see if a waking dream could not give me an idea. I am not sure I did not lose a few minutes, but I gained the following portraiture:—Rather tall than short; high broad forehead; hair scantier in front than behind; grey eye, full of fun; and a face beaming with kindness and intelligence. Rather more like the sleek Cassius than the lean Brutus. He must wear a wide-awake about the yard, farm, and poultry-houses.

I endorse all he says about breeds, and admire them all in their places. I admire the Malays as fancy birds, and on the table, but they would never be popular in a market, and they are not profitable. It must be in that sense Mr. Baily means they gave way to the spirit of utility. For years they were almost the only producers of cream-coloured eggs, and they were highly thought of; but now we have so many breeds that do the same, they are not so much sought after. The long, hard leg and thigh of this breed, and the comparatively small breast are not attractive in a market. They look more muscular than succulent, but eaten very young they are remarkably good-flavoured, more so than many Pheasants.

I believe all breeds to be popular must be remunerative; they must pay either in eggs or for the table, and to take a high standing they must do both. Polands are beautiful. They are good layers; but they are delicate chickens, and not table fowls. I believe next to the Dorking, the Brahma is the best in all senses. I will leave it for others to fight their battles as to purity, colour, or race. I speak well of the bridge that carries me over. They have supplied me with eggs all through the winter, and they and their chickens have defied frost and snow.—B.

**POULTRY CLUB.**

HAVING seen in your Number for February 7th a letter from "A TIMID EXHIBITOR," I observe he infers Mr. Douglas to be a dealer in poultry because he has sold £300-worth to one person, thereby imputing to the Poultry Club a breach of one of its leading principles. All I have to say is, that if he will take the trouble to make a list of our leading exhibitors, amongst whom I would call his attention to Lady Holmesdale, Mrs. Fergusson Blair, Lord Binning, Sir St. George Gore, Captain Hornby, Captain Heaton, Mr. C. Felton, &c., whose great successes in breeding and exhibiting have caused their surplus stock to be closely looked after; if he can term these parties dealers in poultry (a fact I have still to learn), I will grant he has something to write about. As to the Judges appointed by the Poultry Club, to which he imputes such unworthy motives, their motto might very properly be "an open field and no favouritism." As he shelters himself under a *nom de plume*, I think his letter requires no more comment from—R. W. BOYLE, Rosemount, Dundrum.

**POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.**

MR. GEYELIN's article in your Journal of the 7th is calculated to seriously mislead any person who accepts the figures contained therein as facts.

With your permission I will point out a few items that I believe to be wrong.

First, Mr. G. gives an estimate of the revenue and expenses of one chicken six months old, as follows:—

REVENUE.		EXPENSES.	
	s. d.		s. d.
Selling price .....	2 6	Interest, rent, fuel, &c. ....	0 3
Feathers .....	0 1	Cost of chickens when	
Manure .....	0 3	hatched .....	0 2
		Food .....	0 9
		Labour .....	0 2
		Profit .....	1 6
	2 10		2 10

Now, a chicken cannot be fed six months for 9d.; it should be 1s. 6d., which would reduce the profit to 9d.

Second, the estimate for one breeding hen shows 150 eggs at 10s. and 24 chickens at 3d., but if the eggs are all sold none can be hatched; the same occurs in the estimate for one laying hen.

Third, the amount credited for manure is considerably too much, as at least two-thirds of the manure produced is lost.

Fourth, Mr. G. takes credit for 90,000 eggs produced in the winter and selling at 15s. per 100 (See page 16.), forgetting that he has previously taken credit for the sale of the same eggs at 10s. The amount to be credited is simply the difference between 10s. and 15s.

I do not think that £500 per annum could be calculated upon as the extra price for choice birds.

The subjoined statement will be found much nearer the fact than that of Mr. G:—

REVENUE.		EXPENSES.	
50,000 chickens at 2s. 6d. ....	£6,250	50,000 chickens, interest, fuel, rent, &c., at 3d. ....	£625
Feathers at 1d. each .....	208	Cost, when hatched, at 2d. ....	416
Manure at 1d. ..	208	Food at 1s. 6d. each .....	3,750
2,000 laying hens at 180 eggs per annum, at 10s. per 100... ..	1,800	Labour at 2d. ..	416
Manure at 6d. ....	50	2,000 laying hens, interest, rent, &c., at 1s. 6d. ....	150
1,000 breeding hens at 150 eggs per annum = 150,000		Food at 4s. 6d. each .....	450
Deduct eggs reserved for hatching .....	60,000	Labour at 1s. ..	100
		1,000 breeding hens, interest, rent, &c., at 3s. 6d. ....	175
		Food at 4s. 6d. ....	225
Manure at 6d. ....	25	Labour at 2s. ....	140
Extra profit on eggs during winter .....	225	Commission on sales—10 per cent. ....	956
Extra price for choice birds ...	500	Carriage, packing, &c. ....	200
			£7,563
		Profit .....	2,153
	£9,716		£9,716

I allow 60,000 eggs to produce 50,000 chickens. I presume any one would be well satisfied to raise ten chickens out of twelve eggs, which is the same proportion.

Mr. G. charges 3s. 6d. for each breeding hen for interest, rent, fuel, and sundries, but charges only 1s. 6d. for the laying hens for the same purposes.

I think it is a question open to serious doubt whether 50,000 chickens could be sold at 2s. 6d. each.

I have not the pleasure of knowing Mr. Geyelin, but I beg to assure him that I do not dispute his figures simply for the sake of disputing; but I feel that were such a statement allowed to go uncontradicted some might take it as a basis for their own calculations, and then nothing but woeful disappointment would await them.—C. S. J.

### CRYSTAL PALACE BRITISH AND FOREIGN BIRD SHOW.

THERE is, in our opinion, no item in the Crystal Palace Company's winter programme possessing more attraction, and of greater interest, than the annual Show of British and Foreign Birds.

The one upon which we have now the pleasure of commenting commenced on the 18th inst. It is a splendid exhibition of small birds; and, although we have extolled the merits of previous collections, yet we have no hesitation in saying that the present one excels all others in the number and the splendid condition and quality of the birds; and we regret that the weather was so unfavourable as to prevent a larger number of visitors from attending so fine a show. We are glad to find that the Company have been discreet enough to change the day of opening again to Saturday, as it must be more profitable alike to the Company and to the exhibitors. Our notice was specially attracted by the beautiful condition and magnificent plumage of the specimens in general. The entry for varieties contained some very interesting examples of the freaks of nature in the way of perfect albinos, consisting of a Thrush, a Linnet, a Jackdaw, and a Blackbird, of which, perhaps, some uninitiated individuals will be incredulous; but there are the stubborn facts, which cannot be denied.

We observed some very fine representatives of the Blackbird, Bullfinch, and Goldfinch, and also some exquisite specimens of the King Parrot. Cockatoos, Grey Parrots, and Australian Paroquets were also objects of great attention.

With reference to the Canaries, although we cannot say that the Belgian class was so fine as last year, yet the London Fancy, and the Norwich and Jonques, as well as the Lizards, made up for the deficiency.

The Goldfinch and Linnet Mules, especially the Linnet, were very fine.

There were two entries of Pheasants, and we should like to see the numbers in future increase.

The classification of the birds, and the various arrangements in connection with the Show, were admirably carried out, and too much praise cannot be bestowed upon the parties who were responsible. The Judge must have had the same, and even greater, difficulty as at the Show last year, in awarding a prize to a class in which all specimens were so equal in merit; and it is only one who has a thorough knowledge of ornithology that could discover any difference between one bird and another.

### MALAYS ON THE TABLE.

PERHAPS you will allow your "Persian correspondent" to add a line to "WILTSHIRE RECTOR'S" kindly story of his visit to me, and this in simple justice to the Malay. It so happens that the bird in question, which appeared on my table, was not the bird we had eaten three weeks before. In fact, it was like the Irishman's pig, which, when killed, he declared to a friend, "did not weigh as much as he expected, and he never thought it would." Well, it was the same with this identical bird, it did not look as well as I intended, and I never thought it would. I was afraid of it, and I confess that I was somewhat crest-fallen, when, removing the cover, I found the breast as our genial "WILTSHIRE RECTOR" described, "sharp and thin." In justice to the Malay, I do not believe this is generally the case; long-legged as they certainly are (a friend of mine says he should be afraid of their looking in at his bedroom window), yet it is wonderful how a bird, which when hanging by his legs on a nail, has these on the nail "here," and his head "yonder"—I say it is a mystery how his very long continuations can be packed and trussed up to make a seemly bird on the table, but it does, and I can only hope I may yet have the great pleasure of convincing "WILTSHIRE RECTOR" on this point, as much as I have converted him as to their living good looks.

I do not wish to report him to his Bishop, but I must say that I thought we both of us worshipped the sun, or at any rate, we greatly admired him. The visit was in very wet weather; but lo and behold the sun shone brightly all that day, and Englishman-like, we continually commented on his appearance and beauty. &c. That night, if I mistake not, it rained furiously. Well, I must say I am "Persian" enough to have some veneration for that great luminary, especially when he shines on so pleasant a meeting as ours was. I will only add, many thanks to "our Journal" for being the means of introducing me to one who is a kindly genial lover of nature and her varied charms, and who is so warm-hearted and friendly to boot.—Y. B. A. Z.

### HOME SUPPLY OF EGGS AND POULTRY.

Is there any valid reason why England should not supply her own wants in the shape of eggs, poultry, and rabbits? I dare say the money we pay foreign countries for these necessaries, does not fall far, if at all, short of £500,000 annually. Can they not be produced as cheaply, abundantly, and profitably at home, as in France and Belgium? Is it not time that some efforts should be made to solve this problem? I am aware much has been done for the last few years to improve the breeds of our poultry, but I have never heard of the production of eggs and poultry having been attempted in a large way, as a matter of trade or business, though I have often been told that to make this stock pay they should be kept in such numbers as to employ the whole time and attention of working people. M. de Lavergne estimated the value of poultry in France at £8,000,000, while that in England was no more than £800,000.

As a national branch of rural economy, we know nothing in England of the breeding and management of poultry:

hence practical men never think of embarking in a pursuit which is found so profitable in other countries.

We sadly want sound, reliable, practical information on this subject, and if through your columns some of your correspondents will endeavour to ventilate this question, much public good may be the result.

If one acre of average land were cropped with the grain, pulse, and roots most suitable for feeding poultry, how many head should it maintain for one year? Again: What might be a fair moderate profit to expect per thousand in keeping poultry thus on a large scale, assuming suitable houses, warmth, care, and ventilation for such stock?

I have heard and read much on the subject of artificial incubation, and I knew a lady who produced all her own poultry by a most ingenious incubator of her own invention, but I never could ascertain how far the system could be

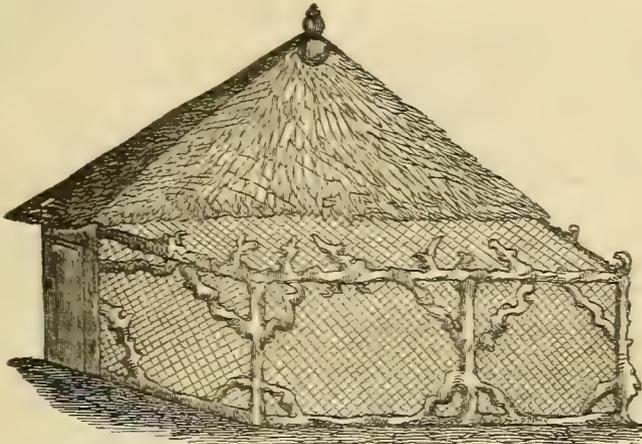

relied on in a commercial point of view, which is the practical test of its merit. If, undoubtedly a success, then I can see no limits to the profitable production of poultry in England. Turkeys and Geese of the largest breeds are now worth very nearly as much as a fat sheep of the smallest breeds, and it is passing strange that you must give 2d. for a "new-laid egg," when you may buy a quarter of wheat for 32s. High authorities tell us it does not pay to feed oxen, and farmers now say they are selling grain at prices for which it can hardly be grown, so I am induced to ask if the experiment of a regular and well-managed poultry farm would be likely to succeed? for if so I should be very well inclined to try if England cannot produce eggs and fowls as cheaply as France; and, further, if the air of our own happy land is not fully as congenial as that of Belgium to an—  
OSTEND RABBIT.

### ORNAMENTAL HEN-COOP.

PERHAPS "F. P.'s" desire for an ornamental hen-coop may be found difficult to satisfy in the old stereotyped form, so I send you a drawing of a pheasantry we had many years ago at Stanton Lacey, near Ludlow. I have often thought that a dwarf portable construction after that pattern might advantageously be made to supersede the old style of coop. The thatch of the above pheasantry was of heather; but in its absence reeds or straw could be substituted, and the roof, in the case of the coop, could be made moveable, and fastened by iron hooks and eyes. From being square at the base, it would prevent the sun's striking the pen with too much force at mid-day, and would also render the coop warmer at night.

For combining neatness with the safe housing and protecting both pheasants and chickens in their young and tender state, when I sent you some papers on rearing the above, you illustrated at page 134, Vol. VIII., May, 1852, a description of coop which we have always made use of for the

purpose; and when neatly made, and painted a lively green colour, I incline to think it would not be thought otherwise than ornamental even in the kept grounds. I always thought them ornamental rather than otherwise on the lawn, backed by evergreen shrubs, &c. The late Earl of Craven was wont to have a number of them on the lawn at Hampstead Lodge, occupied by Bantams with broods of Pheasants and Partridges. A dry lawn or grass plot is the proper place on which to set the coop, even when occupied with chickens. The net protection, figured with the coop, serves admirably for the young chickens to feed under, as well as to shield them from birds of prey and other disagreeables during the day. The front sliding board acts as a preventive against rats and other prowling vermin

Length, 29 feet; height, 6 feet; width, 12 feet, including the back building.

during the night. It should be withdrawn in the morning, by sunrise, and the coop shifted to a fresh position.—  
UPWARDS AND ONWARDS.

### SOMETHING ABOUT GOLDEN HAMBURGHS.

As the shows are nearly over this season, I think one may say something with respect to judgments given. First, I will take Leeds. I cannot think that any good judge of the Hamburgs would have placed the prizes for Golden-pencilled where they were placed had there been a good light. It must be remembered that no class of fowls require the same amount of good light as the Hamburgs; because (after pure white ear-lobes, and fine straight combs set firmly on their heads) they are strictly a bird of feather. I know one man who sent two pens of Golden-pencilled Hamburgs, one a very good pen indeed, the other worth nothing except for the table; the bad pen was awarded a third prize and the good one was unnoticed; and other mistakes occurred in the same class, that never could have been made with good light and good judges. I am satisfied, if the judges had sought to favour the aforesaid exhibitor, that they could have done so by giving the prize to his good pen; and judges must know, that there is no class of men who know really good specimens, so well as they who have striven ever since the show began with a constant aim to perfection.

By-the-by, this brings me to the Poultry Club. There is one question I should like to ask the members: How will they make congenial the dark gold ground with the light gold ground in both Pencilled and Spangled Hamburgs? I have seen good specimens in both light and dark ground. I like the dark ground much better in both classes, and yet I have seen men who said they preferred the light ground because it showed the black much better.—AN OLD HAMBURGH BREEDER.

### PRICE OF NEW-LAID EGGS.

WHEN in reply to your correspondent, "C. S. J.," I stated that the price of eggs, like that of everything else, must necessarily be regulated by the demand and locality, I considered the subject at an end. Not so, however, with "C. S. J.," who evidently is anxious to be introduced to a salesman, who will purchase eggs not from a poultry-breeder, nor even from a person who buys them of farmers, but from one who buys the eggs third hand as fresh laid. In your No. 199, endorsed by your editorial remarks, "C. S. J."

says he buys from a man new-laid eggs at 8s. per 100, and, of course, the man must get a good profit, as he buys them of farmer's wives. In your No. 202, "C. S. J.," says again, that he is in a position to supply a few hundred new-laid eggs weekly (very likely), and that since my reply he has been in London, and could obtain no higher offer than 5s. per 100 for fresh-laid eggs.

Now, how does "C. S. J." know that such eggs are new laid when he buys them second-hand? And how could a respectable London salesman assure his customers that the eggs from "C. S. J." are really new laid?

London tradesmen are too wide-awake to give the price of new-laid eggs for such as do not come direct from a well-known and respectable breeder.

Any poultry-breeder consigning regularly to an honourable Leadenhall salesman will always obtain fair returns; or I can, if it were necessary, give my authority, that even in the height of summer new-laid eggs bring 8s. per 100 in Leadenhall Market.

No person is ignorant of the fact, that a manufacturer will command a far higher price for his goods in the regular course of trade, than a person can obtain for the same goods if he is not an accredited agent to the manufacturer, but simply buys bargains. On my part this subject is closed.—G. K. GEYELIN, C.E., *London*.

### TURKEYS AT EXHIBITIONS.

We have observed your announcement of the Bath and West of England Poultry Show, in June next, and its schedule has been published, in which we notice a liberal increase of prizes in some of the classes—alas! not in ours. In this, as in too many instances, though we pay the same entrance fee, the poorest prizes are allotted to us. May we ask is this consistent with the complaint so often made of us, that we are "so hard to rear?" Or are we mistaken in our notion, that articles are more valued by the difficulty in procuring them? But the information we would most earnestly solicit in this: Have the Committee of the above-named Show made a further extension of their generosity in the increased size of our pens?

The undersigned writers of this have but a philanthropic motive in this inquiry, inasmuch as for their comfort their owner has determined upon not exposing them at Hereford, to the imprisonment their revered ancestors endured at Bristol. For ourselves, fond as we may be of display, we are not prepared to annihilate our beautiful fans in the niggardly space we are likely to meet with at Hereford. Though our career is still youthful, we have as yet held our laurels against every competitor, and may, therefore, justly subscribe ourselves—FIRST PRIZE TURKEYS.

### YOUNG AND VIGOROUS<sup>Q</sup> QUEENS.

I HAVE much pleasure in acceding to the polite request of Mr. Edward Fairbrother at page 62.

The importance of having young and vigorous queens at the head of stocks can hardly fail to arrest the attention of even the comparative novice in bee-keeping, while the apian of enlarged experience must have been struck at the great diversity that exists in the breeding powers of queens. The preservation of those singularly prolific mothers frequently met with should be the care of all; but to such as keep their bees on the depriving or non-swarming principle it is indeed "the great desideratum."

My attention was early attracted to this point, so early indeed as the very commencement of my apian career. The first hive I could claim as my own exclusive property was a weighty prime swarm of that season with a queen, therefore one year old at least. Against the coming summer various were the domiciles prepared for all expected probable and improbable swarms. Anxious was the expectation and vigilant the watching; but no swarm emerged either that good season or in the two favourable ones that followed. I recollect my hopes were all along buoyed up by the yearly-increasing number of drones, being then unsophisticated enough to look upon the unusual preponderance of the male element as an augury of ultimate great success, instead of an indication of the worn-out condition of my aged queen. The last season the drones exceeded all bounds; and my

patience being thoroughly exhausted, I fumigated the hive (then very light), searched for till I found and examined the venerable monarch, and destroyed her, adding her few remaining subjects to another colony.

This early impression was not easily effaced. Your facetious neighbour *Punch* somewhere wittily remarks that, "there are two things a young man rarely forgets—his first love and his first cigar;" and in like manner the young bee-keeper does not readily forget his first hive and the lessons it taught him. I ever afterwards kept a sharp look-out as to the age and breeding capability of every queen I possessed. My apiary being wrought at first exclusively on the natural-swarming principle, I took care at the end of the season to preserve at the head of my stock-hives only such young queens as promised well, and subsequently, when the depriving system was combined with it, placed my picked queens at the head of the depriving-hives. Latterly, since I have eschewed natural swarming altogether, I procure young and vigorous queens after this fashion: As the season draws to a close I make a tour of inspection through the cottagers' apiaries in the surrounding district. They as a rule invariably dispose of their prime swarms at the end of the season, as out of them they can generally realise most money, or, failing a purchaser, most run honey, consequently their queens are necessarily one year old. I generally purchase a few second or third hives whose population speak well for the fertility of their queens, or any prime swarms of whose success the cottager is not unnaturally proud, and such as I feel confident will irradiate the countenance of our blind parish honey-dealer when it comes within his grasp. The teeming population I then for a consideration bespeak, and save them from his ready brimstone match. On their being brought home I drive the stock whose queen I wish to dethrone into a hive of like dimensions, cage the queen, and feed liberally at dusk. I destroy the old queen, and place the box containing her subjects beneath their own hive, into which the stranger bees and their queen have been previously settled, then gently draw the slides of the lower box; a few puffs tobacco smoke to both, and the morning light invariably reveals a most pacific union. In all my experience I never found a queen suffer by such a procedure, or, when the queens were on a par, and neither removed, did I ever find the stock subsequently queenless. Would that I knew as almost infallible a mode of introducing queens singly.—A RENFREWSHIRE BEE-KEEPER.

### OUR LETTER BOX.

MR. DOUGLAS.—Under the heading of "A TIMID EXHIBITOR," I think Mr. Douglas has forgotten himself when he says he has not dealt in poultry for two years. In my former letter I asked a very plain question; and again I ask another, Who claimed the first-prize pen of Game Bantams at the show held at Belle Vue near Manchester last December, and sold them for a good profit at the same place? Why, Mr. Douglas, one of the Judges, who has not dealt in poultry for two years! and if I mistake not he had the boldness to claim them before the Show was opened. Facts speak for themselves; and again let me confess that I am a timid exhibitor, particularly so when I hear of a dealer thus acting being a judge of my produce against those he has sold.—A TIMID EXHIBITOR.

HENS NOT LAYING (*Cochin-China*).—Eggs have been unusually scarce. If your hens are old that will be the reason. You can only expect winter-laying from pullets. We have no doubt the severe weather has much to do with it. A change to warm days would make a great difference.

WASHING WHITE FOWLS (*Snowball*).—Wash the birds with soap and water. Use a sponge, and wipe the feathers straight down, as it is only the outside that is dirty. Put them in an open basket before the fire with some soft straw, and let them stay till dry. It is never safe to put other birds with Golden Pheasants, but if you do we advise the Bantams.

EGGS DESERTED FOR A TIME—CROOKED TAIL (*Subscriber*).—In hot weather we should not think the eggs had suffered at all by being deserted for four hours, but the temperature has been unfavourable for such an accident. You will easily ascertain by breaking one of the eggs whether they are spoiled, and it will be the safest plan. If you object to that you may watch the progress of hatching by holding the egg before a strong light. The twist of a cock's tail will probably descend to some of his progeny, but not to all. It is always bad policy to breed from such an one.

EXCESSIVE DEVELOPMENT OF SPANISH COCK'S FACE (*Country Poultry Fancier*).—We think you may trust to the bird for all you require. A more humane method is to fasten the eyelids up and down with strips of strong plaster. Even this causes the bird much misery.

LA FLÛCHE FOWL (*D. P. F.*).—The reference is to our own Journal. (*Cochin*).—La Flèche fowls can be bought of Mr. Bailey, 113, Mount Street. We published very full accounts of them and drawings two years ago. They are marvellous layers, and very good table fowls, but they do not sit.

A FALSE ALARM (*Jonas Jackson*).—We are happy to be able to relieve your fears by informing you that the bee which accompanied your letter is not a queen, but a worker whose abdomen is much distended, probably by dysentery. Moreover, if your Ligurian stock be pure it could scarcely have proceeded from it, since it is certainly of the common black species.

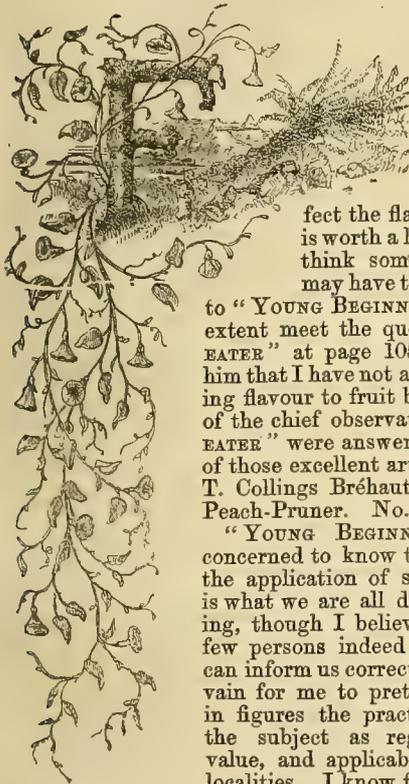

WEEKLY CALENDAR.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 48.6°, and its night temperature 32.8°. The greatest heat was 70° on the 4th, 1860; and the lowest cold, 15°, on the 4th, 1852. The greatest fall of rain was 0.84 inch.

HOUSE SEWAGE :

ITS EFFECTS AND MANAGEMENT.

FRUIT-EATER

(may his crops always be bountiful and of first-rate flavour), says, "How this sewage watering should affect the flavour of the fruit is worth a little inquiry." I think some observations I may have to make in answer

to "YOUNG BEGINNER" may to some extent meet the queries of "FRUIT-EATER" at page 105; and I assure him that I have not arrived at imparting flavour to fruit by chance. Some of the chief observations of "FRUIT-EATER" were answered at once in one of those excellent articles by the Rev. T. Collings Bréhaut, "The Modern Peach-Pruner. No. 3."

"YOUNG BEGINNER" is "most concerned to know the truth" about the application of sewage, and that is what we are all desirous of knowing, though I believe there are very few persons indeed at present who can inform us correctly. It would be vain for me to pretend to work-out in figures the practical bearings of the subject as regards quantities, value, and applicability to different localities. I know from my own experience of house sewage that pro-

duction, as well as flavour, in fruits and vegetables, is greatly increased thereby, and that the time has now come when, the laws of chemistry being understood, those who think upon the subject will no longer from a sense of false delicacy remain averse to the application of house sewage to the land. How unreasonable is it for us to spend millions annually for guano whilst we poison our streams with excreta which would more than compensate for the loss of the guano. The latter is only fertilising according to the amount of ammoniacal salts which it may contain, and the very same salts largely abound, along with many other organic and inorganic substances, in sewage—such as are necessary for building up the structure of plants and fruits, particularly of the latter in their unripe state—viz., humus, potash, soda, phosphate of lime, carbonic acid, hydrogen, nitrogen, and oxygen. The latter exists not only in the atmosphere, but is always active in the soil when this, by good drainage and surface stirrings, is kept pervious and moist, promoting warmth and the decomposition of organic substances, and convert-

ing old into new compounds. By it the starch and gluten are converted into mucilage and sugar in the ripening of fruits; and the soil being porous and moist at that time in particular there will be more oxygen and warmth at the roots and more flavour in the fruit.

I discontinue the application of sewage at the latter period; for although the spongioses of the roots have the power to reject solutions which may not be wanted at the time either for growth or fruit-bearing, it would be unnecessarily taxing the rootlets to separate those solutions from the water which the plant does not want, and wasteful besides in the cultivator to give manure at a time when vegetation only required plain water. And here opens up a problem for those knights of the spade and the hoe who dung heavily, dig deeply, and take culinary crops from their fruit-borders, or who, with the common hoe (which along with the common rake I have many years laid aside; even the occupation of the spade is to a great extent gone since I have used "Parker's first-quality" five-tined steel forks), are so prone to mould and chop about the roots of Potatoes and other crops—all the deeper apparently because the roots happen to be there. "Various salts have been dissolved in the same solution, and plants with their roots un mutilated have been made to vegetate therein, and it was found that only some of the salts in different portions were absorbed; clearly establishing that plants possess discriminating powers—that they do not in an un mutilated state absorb solutions merely because they happen to be in the soil. And, on the contrary, careful researches have proved that when the roots were cut the plants absorbed all the solutions indiscriminately; and that when these plants were afterwards chemically examined, the salts so absorbed were found in them crude and unaltered." The above is an abbreviation of a paragraph which I read some years ago, and which struck me very forcibly at the time, and I have taken care since then never to crop my fruit-borders, or mutilate the roots of any growing fruit-bearing tree or plant if I could help it. When I find it necessary to operate in that way I do so when the plants or trees are at rest, on the approach of winter if possible. I should not expect to find such delicious flavour in the London, Catharina, and the little Ironmonger Gooseberries, or the British Queen Strawberry, Marie Louise and other Pears, and Cox's Orange Pippin Apple, as we are accustomed to, were I to apply manure in any shape, and mutilate their roots when their fruit was ripening or even forming.

I will relate a case in point. Returning from some city business last December, I called in at Fleet Street to pay my respects to "our Editors," and they informed me that they had just been tasting some samples of Pears I had sent, requesting their opinion of them as to flavour. They said, there was no mistake about the flavour of mine; but that those grown only a few yards off in a neighbour's garden "tasted as if they had been watered with sewage!" It was just the contrary. Mine had been watered with sewage, without the surface roots having been disturbed in the least; the trees were growing in a five-foot border

and trained against an Oxfordshire stone wall. Those of my neighbour have a good brick wall, and a capital border three times the width of ours. A large amount of stable-dung is put on it, and it is deeply dug and heavily cropped with vegetables all the year round, and what unutilized roots remain are, of course, growing or rotting in the sub-soil: crude salts must be chiefly the result; so the fruit "tasted as if watered with sewage." It opens up a wide field for thought and observation, however.

I felt proud, too, to find some of my productions so well spoken of at head-quarters, and if I were to write what I have since heard of the remainder I might, perhaps, be thought conceited: so to proceed. "YOUNG BEGINNER" says that his sewage consists of all the slops of the house, rain water being otherwise disposed of. Are we, then, to consider that this sewage is compounded with the water from a well? Silica, lime, magnesia, and alumina are denominated pure earths, and plants cannot grow in them when watered with chemically pure water, and when the water is drawn from a spring it is generally comparatively pure. But when the pure earths, mentioned above, either united or singly, are watered with rain water, vegetation will then be supported by the ammonia which the rain water contains; and that is a chief reason why the latter is so much to be preferred to that from a spring. However, ammoniacal runnings in plenty would be mixed up in the purest water in the state of sewage. I merely mention the circumstance in passing as showing a distinction between pure and rain water, because the sewage that I use is mixed up exclusively with the latter, and should this not be so in the case of "YOUNG BEGINNER" it is a point of difference, and so far the sewage is of less value for plant life. He next says, as "points of difference," that "his ground is newly broken up, and the subsoil a nearly-pure sand;" but he does not say of what nature the surface is. At any rate it is not sand, and the subsoil being so, it is one of the best for the surface soil to rest on, as it will naturally secure a good drainage. Again, as the soil is "newly broken" up, I conclude it to have been turf, which is also fortunate, as it is full of the decaying roots of the grass and other organic substances, which, with the assistance of sewage in a light soil, will insure production. I empty my tanks regularly as they become filled throughout the year, and during the winter months I apply their contents to the Broccoli tribe and to evergreen shrubs, because their roots at that time are comparatively active to receive the benefit; but the plan actually adopted by "YOUNG BEGINNER" is "to throw the contents of the tank on land intended for spring cropping," which, I beg to inform him, is by no means "equivalent to wasting" it. Stagnant water on an undrained soil will dissolve the richest soluble portions, and thus surcharged every flush of land water would carry them off. Not so, however, the well-drained ground, for it will like a filter take from the sewage water all that is suitable for the growth of plants, and till such time as the plants are there to partake of it the soil will hold this fast. Of that practice and science have left no doubt. Some of the richest water meadows in this country are formed on subsoils of broken flints, gravel, and sand.

It is difficult to state how "much land can be manured by 8000 or 10,000 gallons," about 40 tons of sewage. In the first place it would depend upon the nature of the land. Sandy or gravelly soils however bountifully watered would cry out for "more!" We are informed through the press, that the quantities of sewage given per acre every year in different localities has varied from 8000 tons down to 225 tons; and the worth of the sewage per head is very variously calculated at from £1 8s. down to 3s. 2½d. per annum. We want proper chemical analyses to decide the value of the sewage of different towns. As more reliable data, we read that at Croydon by the use of sewage the increase of the value of land per acre ranges from £5 to £15; and at Mansfield, land worth formerly only 3s. per acre, now lets for £12. At Edinburgh, the sewage has been carried over some meadows for more than sixty years; and some portions of those meadows, formerly barren sea sand, have become valuable property, and crops are now sold from off them annually realising from £20 to £38 per acre. Three hundred and twenty-five acres are there devoted

to the sewage escaping from half the modern Athens, about 80,000 people!

The extract quoted by "YOUNG BEGINNER" I can vouch for. According to my own practice and observation, no limit can be imposed on the words, "any time before;" and that sewage can be most profitably applied to grass, the Earl of Essex gives evidence as follows:—"During the winter, from October to January, or longer, I apply it to meadows for hay, two dressings per acre, with about 50,000 gallons—i. e., 255 tons. I have done this now two winters, and the increase of hay, both in quantity and quality is most extraordinary." An analysis by Mr. Way has also revealed to us, "That grasses irrigated with sewage contain 100 per cent. more meat-making matter than grasses not irrigated." Again: the Earl of Essex writes:—"In 1857, I had nearly seven acres of Wurtzel almost entirely taken by the fly, and during intensely hot and dry weather I transplanted five acres with the assistance of sewage, and, although a transplanted crop, it was the largest I ever had, over 43 tons per acre." Mr. G. Shepherd, C.E., writes—"I have myself made experiments on Turnip seed with town sewage, with the most satisfactory results. As soon as the seed was sown, the land was irrigated with sewage, the seed immediately germinated into strong, healthy plants, and were out of danger from the Turnip fly before the seed not irrigated made its appearance above ground."

I could quote many more passages to the same effect, but I will now return to my humble garden at Woodstock, which "FRUIT-EATER" rightly conjectures to be in "the upper valley of the Thames," the soil here being a sound gravelly loam, 2½ feet deep, resting upon a clay. I find 300 gallons of sewage to the 46 square yards is sufficient to saturate it completely; and this operation twice performed is equal to 60,000 gallons, or 310 tons 12 cwt. per acre. But I do not understand, when I stated this, how it should "seem to lead to discouraging results?" If others are better off than myself I do not see why those fortuitous circumstances should discourage me. I hold fast to what I have and make the best of it. If I had six times as much sewage as this household affords I could use it on the garden, and let the holdings be large or small, I prophesy this will be the feeling of most people in a few years. I have only sufficient sewage in the summer to give to the most important crops, and then only at the times when they are the most immediately benefited by it. Like "YOUNG BEGINNER," the want of more may create in me "unwelcome feelings," but let us persevere and wait on Providence. Perhaps some day a sewage company, limited, will convey their mains, with branch pipes leading from them, near our dwellings? Town sewage although more largely diluted with water, is enriched by animals and from many other sources, and I consider the quality would be equal to the best of mine.

The question, "How to dispose of the winter accumulation?" being answered, I would still advise "YOUNG BEGINNER," if he has some years' certainty and feels an interest in his place of residence, to make the extra tank to hold 3000 gallons, for if it were only to store that quantity of rain water to provide against drought at the time his fruit was ripening, it would prove a good investment. The method of procedure stated for a sandy subsoil would be necessary, and it would take all the money. I do not find it cost more than half that, proportionately, to make a tank here, for the subsoil being a retentive clay the outside lining with puddling can be dispensed with. We have also plenty of stone, which when bedded in good lime mortar, pointed when meant for sewage, and lined, for holding water, with a mixture of Portland cement and fine-sifted gravel, we find to answer. Our water-tank last formed, is excavated below the clay a foot deep into the rock, and if it had been made deeper, under these circumstances, I should have considered puddling necessary facing the rock, on account of the fissures in it. As it was, I caused the bottom to be well rammed-in with 6 inches deep of rather dry clay in small portions by degrees, and with not too large a rammer (even for outside puddling dryish clay well rammed would be preferable to wet puddle, as the latter is apt to crack afterwards), finishing it off slightly concave, and on it was spread a layer of mortar, and on that were laid bricks on bed well set in cement. The mason was new to the work, and mixed the cement with too coarsely sifted sand, and the consequence

was some slight cracks and a leakage. I had the cement, in stripes about  $1\frac{1}{2}$  inch broad, chipped clean away from the stonework where the cracks showed, and the places filled-in again with a finer material formed of two parts cement and one of finely-sifted gravel; then a thick paint made of cement and water only was worked over the whole interior with a half-worn-out whitewash brush, and the tank now holds water perfectly. Our scullery tank is much smaller than the others which catch the principal sewage. When all danger from hard frosts is over, a Warner's three-legged pump with india-rubber hose, is placed near it for the season (all our tanks are fitted with a wooden trap-door, sufficiently large to allow a man to enter and clean the sediment out from the bottom), in order to pump the contents into the sewage-wagon, to be afterwards drawn and emptied into the large tank, and thus to add to the sewage in the latter the oily and fatty matter of dish-washings, which the potash and soda soon render soluble in the water.

Now, in regard to a question of "FRUIT-EATER," he inquires, "How may sewage be best applied so as to avoid the loss of temperature consequent on all surface irrigation?" I answer our family washing takes place once a-month, and the soapsuds are saved in a tub. As soon as the washing is over, or, if that time is not suitable, on any other day that will do, I cause the suds to be heated in the copper. I engage my man for what I call a "long day" on those occasions, and in the evening we set-to in earnest. Into one-third of a wagon of the boiling suds two-thirds of a wagon of sewage is pumped, which reduces the temperature of the mixture to about 90°. That is the way and the heat at which I usually apply it to the roots of fruit trees and vegetables. For orchard-house trees and flowers in pots, I bring the temperature up to 70°, by either mixing hot water with the sewage, or some of itself heated in a pan which I keep for the purpose.

When I perceive indications of red spider or mildew on the wall fruit trees, Roses, &c., I raise the temperature to 130°, by adding boiling soap-suds, and syringe the leaves of the trees forcibly both on their under and upper sides, to the utter destruction of the insects or mildew. They cannot exist in the overpowering ammoniacal liquid. My man as he draws the wagon for my convenience in syringing out of it, although he is by no means over-sensitive as to smell, often amuses me by the contortions of his prominent nasal feature on these particular occasions. The packing of the syringe requires to be renewed after being thrice subjected to heat, and a few drops of sweet oil applied to the inner surface before the syringings are begun, will keep the skin of the hands unblistered. I cannot certainly recommend this hot-sewage cure as being of the pleasantest, but one, or at most two syringings, will thoroughly cleanse the trees of filth, and unless the foliage were kept healthy and vigorous, all the rest would be of little avail.

In the evening of the next day syringe the trees again with clean water heated to 130°, that is as hot as the hands can bear it, and the young fruit and foliage will support it very well, subdued by its passage through the air from the nozzle of the syringe. As regards the ravages of the green, brown, black, and blue flies on fruit trees, the modern system of pinching hinders the very existence of the aphid family.

As sewage contains nothing like the proportion of phosphate of lime that is taken from the land by the different crops, I have a special tub into which all the bones are thrown after they are done with in the kitchen. What oyster-shells we may become possessed of during the year are also tossed into the tub. At this time of year the united contents are pounded on a tough flagstone with the back of a heavy hatchet, and then passed through a sieve with a quarter of inch mesh, all that will not pass through the sieve is pounded over again till all is sifted, and the bone dust is scattered on the vegetable quarters along with the other matters when the ground is being prepared. I intend to sow some on the fruit-borders this spring, as soon as the weather will allow me, and then point it in immediately. Another tub we have contains the sweepings of the chimneys, for soot and common salt are excellent applied as a top-dressing to the soil in showery weather. The first abounds in ammonia, and the second given in moderate quantities promotes the decomposition of the organic matters in the soil. We have this winter burnt a great quantity of

wood in the grates, and I have had the mere ashes sifted from the cinders, and kept dry to apply as a top-dressing on a piece of ground intended for Potatoes.

I take this opportunity to describe my method (see No. 164) of working the ground for Potatoes, and culinary vegetables. It is best to divide the ground into three parts. The sediment from the tanks is cleared out once a-year, about this time, and mixed with road-scrappings in a large opening dug out in a back yard, adding what I call my muck-pie—that is, the refuse from the garden, and all the sweepings, excepting tree leaves, that collect from time to time about a small house and grounds in the country.

Early in autumn, the sooner the better, the above is wheeled to the piece to which it is to be applied, the third of the ground that was occupied with the first and second early Potatoes, and the early Cauliflowers and Broccolis. This patch undergoes a thorough trenching, and the mixture is well worked into the body of the soil, and once in three years is sufficient. The other two divisions are bastard or half-trenched as soon as possible after the Brussels Sprouts, Winter Broccoli, and the Turnips from the ridges are successively cleared away. Just before Potato planting, in March, I cause dry mortar rubbish to be spread over the compartment which was thorough-trenched the autumn before last; and quicklime fresh from the kiln, at the rate of seventy bushels per acre, to be slaked upon it, is spread over the surface, and immediately pointed in on the third division, or that which I mentioned first, to act on inert organic matters, which, if not subjected to the action of the quick lime, would remain in an inactive state probably for years. This spring to the second compartment I intend to apply sifted wood ashes, and on the third piece soot and salt, by way of a change. I have also a fourth part of the garden devoted to Strawberry, Onion, and "flying-crop culture," which, at least, in regard to the Strawberries, is made to undergo a three-course system, and where the spent Cucumber-bed and sewage prove their handywork.—  
UPWARDS AND ONWARDS.

### LONGING FOR SPRING.

SHAKESPEARE makes Bolingbroke exclaim—

"O, who can hold a fire in his hand,  
By thinking on the frosty Caucasus?  
Or wallow naked in December's snow,  
By thinking on fantastic summer's heat?"

And although the power of imagination be to a degree transposing, yet none, I suppose, would gainsay the great bard's decision on this point of its impotence to change one season to another, or to make us feel warm while we are shivering with cold. Yet, still, how thoroughly we relish in thought the opposite to that which we possess—how we live and enjoy by anticipation!

To make this clearer by example. I never enjoy "Thomson's Summer" so much as in winter. Let me have the book before me when the frost is on the pane—how I relish this hot picture—

"'Tis raging noon; and, vertical, the sun  
Darts on the head direct his forceful rays.  
O'er Heaven and earth, far as the ranging eye  
Can sweep, a dazzling deluge reigns; —"

Or, again:

"The rage intense  
Of brazen-vaunted skies and iron fields."

Perhaps this delight of the mind in the opposite to that possessed by the body is the reason, or is one reason why books abounding with descriptions of rural scenes and pleasures have been most frequently written while their authors resided in towns; yea, in the great city itself, and even within its prisons. For instance: Bloomfield wrote his "Farmer's Boy" in a London attic; then by the power of imagination he beheld, and, doubtless, himself enjoyed with keen relish—

"Stop'd in her song, perchance the starting thrush  
Shook a white shower from the Black Thorn bush,  
Where dew-drops thick as early blossoms hung,  
And trembled while the minstrel sweetly sang."

Was there ever, I would ask, a more delicious rural picture seen and penned, when the author's eyes fell on nothing more fascinating than the common-place furnishings of a journeyman-cobbler's stall?

I have been led to these thoughts by the winterly prospect as I gaze out of my study window upon the broad snow-covered valley to my right, and the umbrageous park to my left.

The other night when coming home from a penny reading meeting (I hope our readers support penny readings—aids to education as well as sources of great amusement to the working classes), my feet at each step scattered the snow then embrowned by thaw, for the snow seemed literally flowing away. But, lo! a change came in the night, the frost returned, and gently, most gently, and amply too, fell the beautiful snow. In the morning I beheld a scene rarely to be looked upon, except in a picture. There had been no wind, hence every little branch and tiny twig bore its white load, and bright and glistening lay the snow, in park and garden, just toned down and its beauty heightened by a slight mist. There was the snow upon the earth, and upon everything growing up from the earth, whether it was a lofty Elm, or a dwarf standard Rose. A delightful picture until the thaw came, and the trees again stood out black and naked, though still knee-deep in snow. By-the-way, some of my trees and shrubs were broken before I could get the snow shaken off them. Still on the ground lies the snow, too deep to disappear before a gentle thaw, though it is dirty and ribbed with brown now, the surface of the ground looking like a dissipated man's face on the morning after the poor wretch has had what he calls, "A night of it."

By-the-way, how strangely and variously frosty weather alters, and not for the better, the human countenance. A summer beauty, dependant for smooth complexion on soft air, looks now no beauty at all. Then, perhaps, a well-featured face is now spoiled by a very red nose—another has a blue tinge on nose and cheek—another has a deep purple hue, as if "painted with port," as a lover of that now old-fashioned wine expressed it, and so on, while in contrast, a ruddy face of other weather is now pale, almost dead white; and even dear little children, the soft-cheeked and the peachy-bloomed, look mealy and queer. N.B.—Let no one have his, or especially *her*, likeness taken in frosty weather.

But, I was speaking at the beginning of this paper of the mind flying off from the present, and hugging in thought a future season. Strange feeling this of a wonderful yearning longing. Crabbe could not exist without a sight of the sea at least once a-year, and the longing at times came over him so strongly, that it is said he one day mounted his horse and rode forty miles to gratify it. Then, again, Sir Walter Scott could not live many months, without a peep, at least, at the Heather. I find myself amid the snow the victim of an intense longing for spring. I pine for a sight of the spring flowers—the Primroses, the Celandines. Oh! give me spring flowers! Golden Alyssum, varied Polyanthus. Oh! for a Jonquil in my border, a bunch of Wallflowers on my table, or a single Hepatica in my tiny specimen glass, to look at while I write. The spring flowers bloomed badly here last year, and shall I have any this year? is my thought after that dreadfully dry summer. Garden disappointments, like disappointment in love, are terrible things, hard to bear, long to recover from.

Four years ago, that wicked insidious black frost, a very villain, for he came on Christmas-eve, a jovial kindly time, and villain-like in disguise, for I was not aware of his dire presence—"Only a bit of a frost this morning," I said, as I drew up my blind—further a villain, for he killed the young and tender; for that year the Hybrid Perpetuals flowered late, and all things in the garden were, what the gardeners here call "froom"—that wicked frost (to close this long and disjointed sentence), killed my Cloth of Gold Roses on my south front. I knew not my loss for a long time, I began to suspect, then to fear. Then, to buoy up my hopes, the higher branches sent out tiny shoots; but these were merely owing to some little sap left, for the first sun made them wither and die. So in April, knife in hand, I attacked my precious darlings. Sweep down came the long branches, and bare and miserable stood my wall—desolate and naked. I have not quite recovered that blow, neither have I got Roses as yet to equal their predecessors; but I have taken the precaution to sink the budded part below the surface, and I mean to go into flowers with full zest this spring, and forget the past.

*Spring*—the word makes a fountain of joy to spring (alas! a pun even when writing sentiment. I am a candidate for the hospital for "Incurables"), up in one's heart; but

"Is not the sweet spring tide  
Worth all the changeful year beside?"

A garden-loving friend of mine, as soon as Christmas is forgotten, and the days begin to lengthen, is, she tells me, in the habit of getting down from the bookshelf, for her young people's pleasure and edification, all her books relating to flowers, and the country and spring, so that their hearts may, with even more than young hearts' readiness, meet the season. A garden—who loves it not? I read the other day, that Jeremy Bentham, strange old oddity as he was, utilitarian as he was, yet loved to walk round his garden several times each day. True, indeed, he spoiled the whole thing by the fearful name he gave to these walks. He said they were his "Ante-prandial circumgyrations." Dear me! what a name to give to a stroll round one's garden! Then, I wonder, what sort of garden this philosopher of matter-of-fact circumgyrated. Was is it more than what the Scotch call a "Kail-yard"—a garden of mere usefulness? Did he merely circumgyrate Onion and Leek-beds, or Potato patches, or compost heaps? Had he flowers?—the man who said, that "The game of pushpin had done more good in the world than poetry?"

But to let Jeremy Bentham's ghost rest in peace, or still "circumgyrate," as in the flesh, with "white hair, long and flowing, his neck bare, in a quaker-cut coat, list shoes, and, "Oh! the old guy!" white worsted stockings drawn over his breeches' knees." Return we to the far pleasanter subject of the spring. How I long for it, and what a compensation to life's evils is a love of Nature. It abides—if it leaves one for a-while it returns like an old love, all the stronger for the brief leaving. May we be blessed with a genial glorious spring; may we watch, with the sun shining above us, the tender green of the hedges. Then, when the spring comes, how I love to walk round, not "circumgyrate," my garden each morning; and watch another, and yet another flower, first showing a little point of colour, then open into full bloom. May my hope be realised. Perhaps the colder the winter, the warmer will be the spring. I trust it will be so.—WILTSHIRE RECTOR.

#### HOW TO KEEP PEARS.

SOME three or four years since I was much struck with the tendency in our winter Pears to ripen prematurely in cool wet seasons, and particularly so in the remarkable season of 1860. Somewhere about that period I became acquainted with the fact, that late Pears in the warmer parts of France, particularly the Doyenné d'Hiver (our Easter Beurré), were often in fine perfection as late as May. There was nothing new in what I deduced from this—viz., that our late Pears were not fully matured: hence premature *quasi*-ripening and decay. In 1861 I commenced my experiment of ripening Pears in a greenhouse, on a bench formed of slates about 3 feet from the glass. The roof over the slates was shaded from the time the Pears were gathered, in October, till the end of November, and the shading then removed. The autumn Pears ripened slowly and kept well; the late sorts unusually well till, in January, I found some of the kinds inclined to shrivel; I then placed them in flower-pots with covers to them, still keeping them in the greenhouse, and in the end I had several kinds that ripened well in May.

So far I was encouraged, and last autumn (1864) I determined to endeavour to reduce Pear-ripening and Pear-keeping to a system, the *modus operandi* of which I now give.

I selected a span-roofed orchard-house, 60 feet long by 14 feet wide, with a floor of boards slightly raised, so as to be about 6 feet from the roof. Towards the end of September we commenced to gather the autumnal-ripening Pears; as they were brought in some were laid in small heaps, from one to two pecks in each, and others in single layers. In the course of October the winter Pears were gathered, and placed in the same house and after the same manner. The Brown Beurré, Urbaniste, Beurré Hardy, Gansel's Bergamot, Conseiller de la Cour, Doyenné du Comice, Louise Bonne, Marie Louise—in short, all our finest autumn Pears

ripened slowly and thoroughly, so as to be of excellent flavour. The late Pears did not shrivel, but seemed to be in a very happy condition. In the severe frost that occurred about the 18th of December last some hot water was let into the pipes to keep it out of the house, and on the 24th of the same month all the unripe Pears were placed in new 13-inch flower-pots, in some cases two or three sorts in a pot, divided by thick layers of old newspapers; other pots with a wooden cover to each were then placed in the fruit-cellar, where the temperature during winter averages from 40° to 42°. They have continued to ripen slowly and well, and I am inclined to think I shall have a good supply of Pears till far into April. Joséphine de Malines is just now in perfection, and Bergamotte Esperen and L'Inconnue (Van Mons), just commencing to ripen.

The most remarkable effect of this thorough ripening of Pears in a house full of light and warmth has exhibited itself in Winter Nelis and Beurré d'Arenberg; some fruit of these two kinds were gathered in October, and divided into two portions, part being at once placed in the fruit-cellar and part in the orchard-house; they were gathered from one tree of each sort. Those placed at once in the cellar ripened early in December; those placed in the orchard-house till the 24th of December and then removed to the cellar have ripened as follows:—the Winter Nelis at the end of January, lasting to the 8th of February. The Beurré d'Arenberg are only just now (February 14th), ripening; they are plump, of a bright yellow, and juicy and excellent, as are the fruit of Passe Colmar treated in the same way. These very late Pears are still firm and sound.

The rationale of this mode of ripening late Pears seems to me to be as follows:—The Pears exposed to a warm light climate for two months after being gathered throw off a considerable portion of watery juice, leaving the remainder more inspissated and saccharine; thus tending to the preservation of the fruit for a lengthened period of time.

I have not found late Apples benefited by being placed under the same circumstances as late Pears, because they seem not to require more warmth than our climate usually gives to fully ripen them, with the exception of American Apples; but after one of our wet cloudy summers, which always occur at intervals, many kinds would doubtless be improved by being placed under glass.

Apples keep so well in my fruit-cellar that I have never thought of any other mode of preserving them. At this time (February 14th), the early autumn Apples are sound and plump, and I have often known Hawthorndens to keep till late in March. As this cellar seems to be almost perfect as to its fruit-preserving qualities, I will in a few words describe it, so that if an opportunity offers it may be imitated.

On the crest of the hill, formerly called "Bonks Hill," on which stands my dwelling-house, there was formerly a fosse some 20 or 30 feet wide, forming a semicircle to the north-east: this was evidently excavated for the purpose of a temporary defence. From its position this formed a dry ditch, and my great-grandfather thinking, I suppose, it would spare the heavy expense of digging, threw an arch over it so as to form a vault upwards of 30 feet long and 12 feet wide. As the crown of this arch came within a foot of the adjoining surface rain would have penetrated, and thus make the apartment damp and unfit for a wine-cellar, for which it was intended, he therefore built a large shed over it, so that the earth resting on the arch should be perfectly dry. This is now my fruit-cellar. It has at one end an iron-grated window, which is closed with a shutter in dry, cold, windy weather, and a door at the other. It is perfectly frost-proof, so that Potatoes, uncovered and lying only within a foot of the strong but loose-fitting door, which is truly a ventilating door, never become frozen in our most severe frosts. In this dry, but not too dry, place, with slight ventilation and a very equable temperature, varying from 40° to 44°, from November till the end of March, fruit is kept in great perfection; it seems, therefore, to approach to what a fruit-room should be.—T. R.

THE INGRAM TESTIMONIAL.—In another column will be found a list of subscriptions to the fund for presenting Mr. T. Ingram, of the Royal Gardens, Frogmore, with a testi-

monial in recognition of his services to horticulture, and as a mark of the high esteem in which he is held by all who know him; and we take the opportunity of reminding our readers that the subscription list will shortly be closed.

## VISITS TO GARDENS PUBLIC AND PRIVATE.

MR. JAMES VEITCH'S, CHELSEA.

KNOWING that I was somewhat interested in the new system of double-roofing which my friend Mr. Bewley of Blackrock had originated, and of which he entertained such favourable opinions, I received a courteous invitation from Mr. Veitch to inspect a range which he had lately had constructed on that principle; for with that enterprise which ever characterises this well-known firm they had determined on testing it by their own personal experience, and had (as Mr. Bewley indeed told me when visiting his gardens last summer), sent over their foreman for the purpose of seeing it in operation and taking plans; and although the month of February is not a very agreeable time of the year for visiting gardens, yet as I knew in this wonderful establishment there is always such an *embarras des richesses* that something is always to be seen and learned too, I ventured on the undertaking one day last week, and have put down a few jottings of what I saw and heard. I may at the same time observe that, great as was always the interest attaching to this establishment, it will in future be doubled; for since the death of old Mr. Veitch, the Exeter establishment having been abandoned, the whole energies of the firm are concentrated on their London nursery, comprising not only the splendid concern at the King's Road, but also about thirty or forty acres at Coombe Wood. To London, then have been transferred, not merely the most choice of the plants that adorned the Exeter establishment, but also, what will tend more to the increase of the interest, their able and successful foreman, Mr. Dominy, and the more experienced of their Exeter men. When, then, the alterations now making are completed, there will be so rich a treat for all who really love flowers and plants, and can appreciate them whether they grow them or not, as will make the homœopathic Saturdays at South Kensington hide their diminished heads; and now in its present state there is to every plant-lover abundant materials, even in the depth of winter, to make him forget all the dreariness without in the rarities and beauties within.

The range of double-roofed Orchid-houses is 120 feet long, in three divisions, while a T-shaped house at the end is devoted to cool-house Orchids and other plants which will bear a lower temperature. In these three divisions the Orchids are arranged according to the temperature of the climate from whence they come; the division nearest the boiler averaging a temperature of 70°, the middle 65°, and the further end 60°. The advantages which Mr. Veitch has found already resulting from the plan are great economy of fuel and pipes, for in the very warmest part of the house the heat is maintained by a single flow and return on each side; and even this gives so much heat that it is found necessary to brick in the pipes. Air-shafts are also inserted, by which a constant supply of cool air enters the air-chamber in the centre of the house, and is there heated and dispersed. Besides this, the temperature of the houses is entirely deficient in that dry heat which one so often finds, and there are not those constant variations of heat and cold which are so injurious to the health of plants. These were just the points that Mr. Bewley urged, and I am glad to find that in other hands his success is repeated.

And what shall I say to the plants that these houses contained?—the splendid masses of Dendrobiums and Cattleyas; the glorious Vandas; and Phalænopsis Schilleriana with its curious mottled leaves—more beautiful, however, in their younger state than in their more mature growth—and amabilis with its snow-white flowers; Cypripediums of all sorts, including a new one brought from Manila by Mr. J. G. Veitch (and which I believe is to be named *lavigatum*), now flowering for the first time, and promising to be quite as fine as, and very distinct from, all other known varieties; and then there is that fine plant of villosus which fetched so high a price at Stevens's sale. I can only say that they were the very perfection of growth, that the rarest and most

beautiful forms are there, and that the eye of the connoisseur and the simple lover of flowers would alike be gratified by the fine display there made. The cool house would be, perhaps, of more general interest, as it implies the possibility of Orchids being more generally grown; but I may be allowed to express here an opinion, which I ventured to broach to Mr. Harry Veitch, and which he confirmed—that a great many people will burn their fingers at this experiment, that Orchids will be attempted in this way, which will never do, and “cool house” receive a much more liberal interpretation than the case warrants. Well, in this cool house there were a number of fine plants of *Barkeria*, both *Skinneri* and the higher-coloured variety *superba*; *Celogyne cristata*, which, albeit it may, according to Mr. Gordon, do better in an East-India-house, was doing well here; *Odontoglossums* of various kinds, *naevium* and *Pescatorei*, and its variety *superbum* just coming into flower; and above all, the very varied and beautiful *Lycaste Skinneri*. Talk of the varieties in florists’ flowers, this Orchid beats them all; for not only were there no two flowers alike from the different bulbs, but the same bulb produced flowers differently marked. So free-flowering, too, is it, that on one plant in a small pot I counted ten flower-stems. Mr. Warner has told us how well this lasts in flower in a drawing-room; and those who possess a house which they can heat would do well to see if they cannot grow this very beautiful and free-flowering Orchid for the winter and spring decoration of their houses. Perhaps in this house, however, the plant was a beautiful mass of *Cephalotus follicularis*, which was truly wonderful for its extreme vigour and health, and with its curious little bearded pitchers a most interesting object.

All who have of late years visited Mr. Veitch will remember the beautiful hardy fernery, which was one of the gems of the place. Its place is at the end of the range of Orchid-houses; and it is now to be removed, and a house built there for the purpose of bringing Orchids into when in flower, so as to prevent the necessity of visitors going through the range of houses, oftentimes, especially to ladies, very oppressive. Interspersed as they will be with Ferns and other plants, it will always be a pleasing and interesting spot. But let it not be supposed that therefore Ferns are to be neglected; on the contrary, this is only preparatory to a complete change. A space of ground which now adjoins the greenhouse fernery is to be covered in with glass; and in this a new hardy fernery will be formed, laid out with the same taste as characterised that now in course of removal. Thus, as in the case of the Orchid-houses, there will be a gradation in temperature—the hardy fernery first, then the greenhouse, and then the stove Ferns; so that they who are afflicted with filicomania may gratify it to their heart’s content, for every rare and beautiful form will be found there—and what is more exquisite than the lovely and delicate foliage of this widely dispersed tribe? In the greenhouse fernery were some large masses of that glorious terrestrial Orchid *Disa grandiflora* and its variety *superba*, which Mr. Veitch has imported from the Cape of Good Hope, equalling if not excelling all other Orchids in the brilliancy of its colouring, being, moreover, so easy of culture, that any one with a greenhouse from which frost is excluded may grow it.

It would be simply impossible for me to even enumerate a tithe of the novelties and rarities that I saw in range after range of houses. Amongst fine-foliaged plants stood conspicuous *Maranta Veitchii* with its singularly marked leaves, almost looking as if three separate leaves had been one by one eliminated from the bud and marked with the most striking colours, and for which the premier prize was awarded at Brussels. Then what glorious masses of *Azaleas*! looking pugnacious, I fancied, as if to say, “I have my gloves on ready for the conflict in May and June.” Who can adequately describe the fine collection of Pitcher-plants, unequalled, probably, in any establishment in the kingdom? Then there were such plants of *Lapageria rosea* and *alba*; that fine *Anthurium*, about the best plant sent home by Mr. Weir, and whose name is still *in rubris*, whether it is to be *cordifolium* or *Weirii*. If the latter, it will almost sound like an epitaph if the next accounts of Mr. Weir correspond with the last. Then to lovers of softwooded plants there was a whole house gay with variegated *Geraniums*, on which Mr. Harry Veitch has been trying some curious

experiments, which I hope may produce something. One quarter of the ground, which has been recently taken in and enclosed with a wall, has been devoted to the trying of new plants; this will be a sort of *sanctum sanctorum*, under special watch and ward. Then the Japanese Museum in itself affords occupation for a morning’s investigation, while I had but a couple of hours to run through it all.

Ere I left, however, I acceded to a most kind invitation, not only to go there again in May, but also to visit Coombe Wood; and the results of my visit I hope to communicate. I trust, however, that what I have said may induce some of your readers when visiting London to go down to Chelsea to see this world-famed establishment. They may depend upon it that they will find it at any time far better than a weekly show at South Kensington; and they will meet, moreover, with what is rather a scarce commodity in that fashionable locality—the utmost civility and attention, and a desire to impart any information which it may be in the power of those who manage the concern to give. It has now been for three generations in the same family—a most unusual thing—with every prospect that the fourth will be as active, enterprising, and intelligent as its predecessors.—D., Deal.

### THE STRAWBERRY LA CONSTANTE.

EVER reluctant to obtrude myself on the horticultural public, I cannot refrain from giving my humble experience as to the merits of that excellent Strawberry, *La Constante*, especially as I perceive that in your Number of the 14th inst., that eminent grower, M. Gloede, of Les Sablons, mentions my name in connection with this branch of horticulture, making allusion to this Strawberry in particular.

I have been very closely engaged lately in my own avocation proper, or despite my antipathy to dabbling in troubled waters, I should most probably have forwarded you a line ere this on so interesting a subject. I have not, however, been altogether a passive observer of the opinions lately expressed in your valuable Journal; on the contrary, I have closely scanned them, and weighed their merits.

After a careful observation of the habits and peculiarities of upwards of two hundred varieties of the Strawberry, I can safely say that no sort has given me greater pleasure or satisfaction in its culture, than *La Constante*. I can, therefore, fully endorse the opinions expressed by M. Gloede in every respect. Any doubt as to its hardness, indeed, had never entered my mind, never to my knowledge having lost a single plant of it from any cause whatever, since I commenced its propagation some four or five years ago, from two plants kindly presented to me by that unobtrusive but devoted fragarian, the late Mr. Nicholson, of Eaglescliffe.

The only difficulty that first occurred to me from such small beginnings, was its reluctance to emit its runners, especially early in the season; but this, now that I have a good stock of plants, I must confess I regard as one amongst its numerous merits; for what amateur or private grower of this delicious fruit likes to see his beds choked up with innumerable runners? and look what constant labour is required, especially in large plantations, to repress this tendency in many sorts. This opinion may not be concurred in by those who grow this variety for sale; but even here, as in the case of the amateur, the only thing needed is a little extra vigilance in looking after the earliest runners, and taking care to get them well rooted as early as possible in ground properly prepared for the purpose. Let the earnest fragarian only once accomplish the production of a good crop of fruit from first year’s plants of *La Constante* (and it is easily done), and all other difficulties will soon vanish.

The early planting and the necessary attention to the plants to accomplish this end, will at the same time banish all ideas as to the tenderness of this variety, if any exist; but with me, as with British Queen, the question of tenderness has never arisen. I never mulch or in any way protect my plants in winter. A Strawberry that required such petting would very soon in my grounds, exposed as they are, be dug up. I place my trust, on the contrary, in thorough exposure, in deep trenching, incorporating the soil well with a moderate quantity of well decomposed manure in the

process, and allowing the ground to remain some time exposed to the sun, air, and weather. It is then tolerably firmly trodden over the lines at the time of planting. I plant as early as I can possibly raise my plants (the British Queen annually, from which I get the largest crops; the plants are then dug in), and under this treatment I know of no kinds more hardy, or that stand the most inclement weather better than La Constante and British Queen.

Add to the above Carolina Superba, and you have the best three varieties at present in existence. Any private grower who thoroughly understands the culture and requirements of these three sorts for his main crops, can afford to speculate with the almost endless candidates that compete for his favours for early and late production; but after all, to the above varieties he can always appeal for a never-failing supply of the handsomest and best fruit in size, form, colour, and flavour combined and the greatest connoisseur need wish, throughout the principal part of the Strawberry season.\* There are, unquestionably, several others of very great merit, which it would be almost invidious to particularise; but every disinterested grower must, I think, admit that the above three sorts are unrivalled.

I am anxiously looking forward to the results of next season, to test the merits of La Fertile, Modèle, and one or two other seedlings, from the extensive *répertoire* of that distinguished raiser, M. de Jonghe, the raiser also of La Constante. I am informed on the best authority, that the former will be found to possess all the leading characteristics of La Constante, added to which it produces larger fruit, is extraordinarily prolific, and is more easily propagated.

With regard to this latter point, I have already expressed my opinion. Time, however, will show whether La Constante will thus be doomed to the tomb of the Capulets. Till such is the case I shall pin my faith to La Constante, as one of my greatest favourites, and enlarge my stock of it accordingly.—WILLIAM RODEN, M.D., *The Grange, Kidderminster.*

#### VAGARIES OF MUSHROOM SPAWN.

I HAVE been a successful cultivator of the Mushroom in a proper house, and, not having one of those houses at present, I made up two beds in November with dung prepared in the usual way, and spawned them at a declining heat of about 80°. These beds I made in a cold shut-up shed. I formed them at the end, 4 feet from the ground, the face of the bed having an angle of about 30°. Under these beds I have a chamber, in which I kept up a regular fermentation with dung and leaves, and I always maintained a heat in the beds of about 70° for at least six weeks, with a covering of hay on the top. I then allowed them to cool down by degrees to 55°, which heat they have been at for a month, and yet I do not see the least sign of Mushrooms. I have examined the beds, and I find them one mass of spawn, the threads of which are as thick as a stocking needle. The average temperature of the shed is about 40°. Do you think this is high enough? or can you give any instructions about them? Do you think, if I raise the temperature of the house, that I shall be successful?—H. LEAH.

[It is quite possible that you may yet have a good crop of Mushrooms, though the description of the spawn in the bed, run as thick as stocking needles, makes the matter doubtful, unless there are also plenty of small threads not much thicker than the points of needles. By the bed being so filled with these threads, it seems to prove that all the first operations were well and successfully performed; but it is just possible that your fermenting material, in the chamber below the bed, made the bed at times too hot, whilst the atmosphere of the place was becoming rather cool. In such a bed, in a shed, applying heat from below must be done with great caution. It is safer to keep the bed about 60° by top-covering; and, if the bed is so kept, a lower temperature of the atmosphere around the beds is of

\* La Constante will fruit nearly as late in the season as Elton, and other late kinds, and it may not be generally known as yet, that in consequence of its fine colour, unique, penetrating, ray flavour, and its firm texture, it makes one of the very best preserves. I am aware it will require more than ordinary fortitude to commit so good a fruit to the preserving-pan, but so long as the same space will grow an equal quantity of fruit fit for all purposes, why not, as with everything else in horticulture, grow the superior kind?

less consequence. Even to keep up a moist atmosphere of 55° we would prefer the fermenting-heap to be on the floor of the house, and not below the bed. What we should advise now is, if the beds are dryish, to water them with water at about 80°, leaving them, however, rather dry than wet; then place a little clean straw over the beds, and over that some hay, or even some warmish litter, increasing the quantity until you find the bed, on the surface, warm (about 80°), when you put your hand on it, beneath the straw. A little fermenting matter might also be placed at each end of the bed, so as to block up the outlets of the chamber. As soon as the Mushrooms begin to appear, lessen the thickness of the covering. This heat on the surface will encourage the working and productiveness of the spawn upwards; but too much heat, and continuous, must not be given, or the spawn will thread, and not produce. The heat, thus applied moderately at the surface, does little to heat the spawn, or injure it, to any depth. We have more faith that this system will answer, because you have allowed the beds to be not higher than 55° for a month. Try this addition of temperature at the surface. Of course the temperature of the shed (40°) is too low, but then, by this covering, you can make the atmosphere, near the surface of the bed, 60° or more. Treat your bed out of doors in the same way. Examine the bed, and, if cold at the surface, clear it all over; lay on some clean straw, then a little warm litter, and then a good portion of the present covering, but see that the heat does not increase too much. Perhaps the bed with this 2 feet of covering was too hot. We never had better Mushrooms than in ridges out of doors; but they require some care in changeable weather, and the covering to be proportioned accordingly. We shall be glad to hear how you succeed. We have had fine crops five or six weeks after spawning. We have had, also, fine crops three months after spawning; and we could not tell why the latter were so long in coming. From six to seven weeks is a common time.]

#### ROYAL HORTICULTURAL SOCIETY.

At the weekly Show, on the 25th instant, the objects specially invited were Narcissus, and of these no exhibitors came forward. A few, however, belonging to the Society, also a number of Lilies of the Valley, were placed upon the table. Messrs. Lee, of Hammersmith, sent *Phalanopsis Schilleriana*, *Dendrobium speciosum*, *Franciscea confertiflora*, in excellent bloom, and a nice specimen plant of *Hedera fuchsoides*; Mr. Bull, Chelsea, a fine pan of the Irish Fern (*Trichomanes speciosum*), *Cyperus alternifolius variegatus*, and *Pandanus elegantissimus*; Mr. R. Cox two seedling *Cinerarias*, of no particular merit; and Mr. Greeves, Bayswater Road, a window-box, flower-basket, and bouquets for sale.

#### GLAZING WITHOUT PUTTY.

THIS is by no means new. I remember the late Mr. Knight, of King's Road, Chelsea, pointing out to me, some twenty years ago, a house that was glazed in the way your correspondent speaks of. The bars were painted and the glass fitted on, and three or four coats of thick paint filled up all the crevices and fixed the glass; but the plan had no particular advantage over putty, as thick paint was, on the whole, more costly, and the work was no better done. There was another contrivance adopted at the same time to save the lower squares of each light from breaking; for the condensed moisture penetrated between them and the timber end of the light they overlapt, and the water expanding in frosty weather broke the glass. To remedy this a plate of zinc was put across, and it yielded to the expansion of the frozen water. I believe Messrs. Cottam & Hallam, whose position as hothouse builders was very high about thirty years ago, introduced a plan of glazing without putty, but I cannot call to mind what. It must, however, not have succeeded very well, or it would have been well known ere this. There are serious objections to putty, I for one admit, but with all its faults we have not yet found a substitute for it that is not otherwise still more defective. I hope, however, to see this remedied.—J. R.

## THE ARBORETUM—DECIDUOUS TREES.

(Continued from page 133.)

## ÆSCULUS (THE HORSE-CHESTNUT).

THE Horse-chestnut is a tree of the largest size, and ranks among the most beautiful of all our deciduous trees, both for its magnificent foliage and remarkable flowers. It is the best-known of exotic trees, and has been more extensively planted than any other of a purely ornamental character. So frequently is it met with, that the fact of its not being a native would not be suspected by others than those who have made plants a study, and subject of inquiry. The Horse-chestnut, and its kindred tribe, the Pavia, are best adapted to light soils, upon which they will thrive, although they may be sterile; in tenacious clays they are always stunted and unhealthy.

ÆSCULUS HIPPOCASTANUM is the common Horse-chestnut, and is too well known to need description. Several varieties of it have been raised in different nurseries, and distributed under various names. In some instances the distinction hardly appears sufficient to warrant the assumption of the difference ascribed to them. The following may be regarded as being the best.

Æ. *rubicunda* differs from Æ. *hippocastanum* by its leaves being fuller and more uneven on the surface, and of a deeper green. The tree is also smaller, and of less vigorous growth, the flowers have more red than any of the species, and planted as a single specimen on a lawn, or in a park, this tree is without doubt the most ornamental of the family. Æ. *rubicunda* is sold in some nurseries by the name of Æ. *coccinea*, *rosea*, and *carnea*.

Æ. *OHIOENSIS* is found wild on the banks of the Ohio, in North America. It differs from the common kind in having larger and more undulating leaves, and its fruit is said to be about half the size of that of Æ. *hippocastanum*. Loudon was of opinion that it is nothing more than a variety of the common species, and far inferior to it in point of beauty. By another authority it is stated that it has never flowered in England, but this is not correct, since one of those in the Royal Horticultural Society's Garden at Chiswick, is recorded to have bloomed in 1835, and very probably since.

Æ. *GLABRA*, another North American species, of which little is known, is described as a low tree with leaflets of a pale green, very smooth. "The whole plant is comparatively glabrous, and even the fruit partakes of that quality." It would thus seem to be a distinct variety, but it must be confessed that more information is necessary to be able to describe it accurately.

Æ. *PALLIDA* is a native of the forests of Kentucky, in

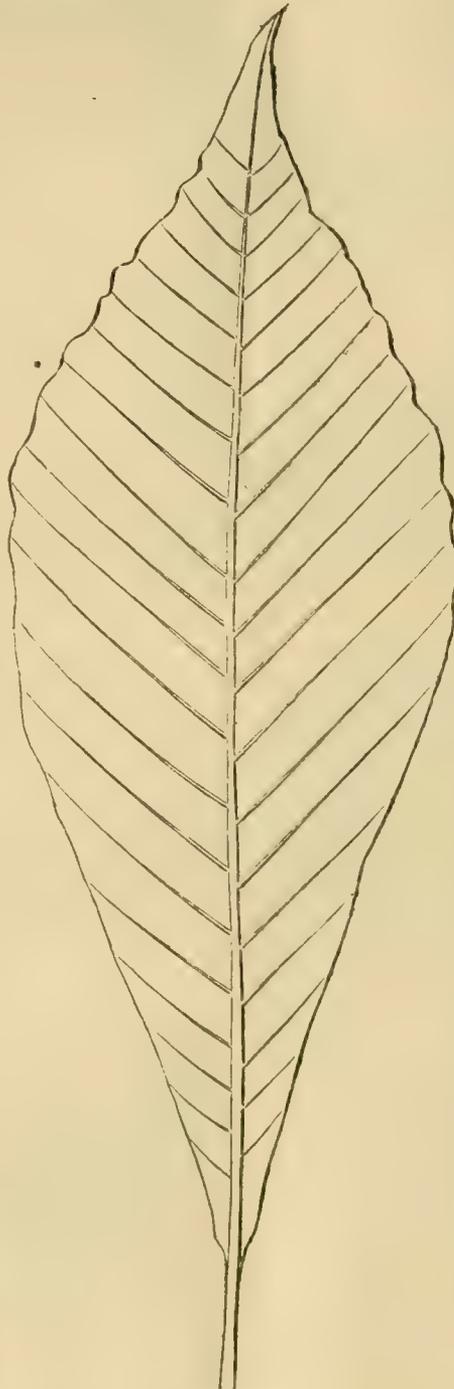

North America, and resembles the preceding. "It is of somewhat more robust growth, and its leaves are not quite so smooth." The proximity of its native home to that of Æ. *ohioensis*, and Æ. *glabra*, would suggest a doubt of its being a distinct species.

A cut-leaved variety of the Horse-chestnut is sold under the name of Æ. *laciniata*, and others bearing the names of Æ. *nigra*, Æ. *præcox*, and Æ. *tortuosa*, have been mentioned. The facility with which plants may be raised from seed has, undoubtedly, produced variations, and in so handsome a genus as the Æsculus, such cannot be unacceptable, and if really good and distinct, would be appreciated, if arboriculture can be restored to its proper rank and share of attention.

## PAVIA.

The Pavia are so closely allied to Æsculus, that it seems best to describe them with the latter, although it is a departure from the alphabetical order originally intended to be followed. The Pavia differ only from Æsculus in their converging petals and spineless fruit; they are also much smaller in size. It has been complained that the Pavia are short-lived, but if they are raised from seed, instead of being grafted upon the Horse-chestnut, which is very frequently done, it will be found that they not only endure for a longer period, but attain a stronger and finer habit. It is true that the propagation by seed would render them liable to vary slightly, but that defect, if any, would be more than counterbalanced by an improved plant. All the species known in England are from North America, where they are called Buck's Eye Chestnuts; but in the colder parts of India two species have been discovered, called Pavia *indica*, and P. *panduana*, which may be found capable of existing in our climate, and may add some new feature to the genus.

Loudon remarks on the Æsculus and Pavia, "That nurserymen who propagate varieties of these and other select-flowering trees, ought always to keep specimen plants in their own grounds, from which to take scions for the propagation of varieties remarkable for some peculiar or distinctive feature. Such varieties should not be raised from seed; because, though there can be no doubt but that the progeny would bear a general resemblance to the parent, yet the particular feature for which the variety was cultivated might be wanting. Early and late va-

Pavia flava.

rieties of all showy-flowered trees are very desirable, because they prolong the season of blooming. Early-leaving varieties of trees, and trees which retain their leaves late

in the season, are also desirable, and in this respect the Horse-chestnut varies exceedingly." As all the species of *Æsculus* and *Pavia* seed freely, and hybridise almost as freely with each other, the *Æsculus* also with the *Pavia*, a great abundance of varieties might be raised. All at present recognised are truly beautiful, and it is not at all to be regretted that their number can be largely increased.

**PAVIA RUBRA** (The Red-flowered *Pavia*) is a slender-growing tree from the mountains of Virginia and Carolina. It produces flowers of a brownish scarlet colour in May and June.

**P. FLAVA** (The Yellow-flowered *Pavia*).—This species differs from *P. rubra* in being a much stronger plant, assuming more the character of a tree. As its name implies, the flowers are yellow; the leaves are pubescent, and much paler than those of *P. rubra*. *P. flava* appears to be the connecting link between *Æsculus* and *Pavia*, as it partakes of the character of both. It loses its foliage at the end of summer, so that it is frequently bare by the beginning of September.

**P. DISCOLOR.**—This must be considered rather a shrub than a tree, as it is seldom seen above 5 or 6 feet in height, when raised from seed, but attains a large size when grafted upon *Æsculus hippocastanum*; it is then said to be short-lived.

**P. HYBRIDA** is described by Loudon as being a very distinct variety, which ought to be in general cultivation. There is a plant of it in the Royal Horticultural Society's Garden at Chiswick. Its flowers are variegated with yellow, white, and purple.

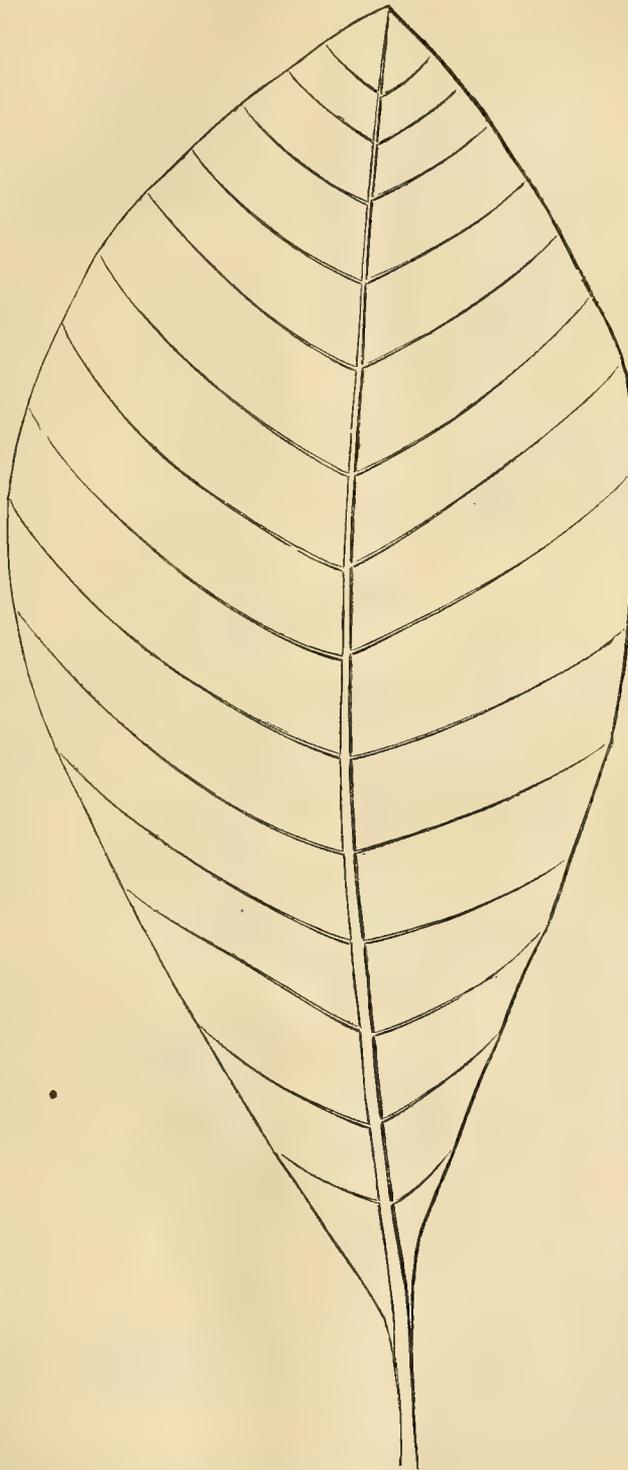

**P. NEGLECTA** is another kind but little attended to, although it is known to partake in all the most striking features of its tribe. Its name is the Neglected *Pavia*, which so far is very appropriate. There is, or was, a plant of it in the Royal Horticultural Society's grounds at Chiswick. Will some influential member endeavour to retrieve the neglect by getting this and other trees almost forgotten, and which are known to exist at Chiswick, propagated and distributed? There is room for a world of good to be done in this way.

**P. MACROCARPA** (The Large-fruited *Pavia*).—Loudon

thought this kind intermediate between *Æ. hippocastanum* and *P. rubra*. "The leaves are large, smooth on the upper surface, and shining. The flowers are nearly as large as those of the common Horse-chestnut, but the petals are less spreading, and of a pale red colour mixed with yellow. The branches are spreading and loose, and the whole tree has an open, graceful appearance, quite different from the compactness of form, and rigidity of branches which belong to most of the varieties of *Æsculus* and *Pavia*."

**P. MACROSTACHYA** is a shrub with loose racemes of white flowers, with long projecting stamens, which give the spike a fine fringed appearance. It is also remarkable for its large deep green leaves, entire, and very even in their outline. "This variety comes into flower about a month or six weeks later than the other *Æsculaceæ*, and continues flowering, in the case of large plants, on moist soils, for three months, or longer, forming one of the greatest floral ornaments of the shrubbery at a season when very few trees are in flower. The flowers are agreeably fragrant, and the spreading leaves being supported on long slender petioles, which from their graceful disposition, combined with the feathery lightness of the racemes of flowers, gives the whole plant an air of elegance quite different from any other species of dwarf *Pavia*."

—ADOLPHUS H. KENT.  
(To be continued.)

*Pavia macrostachya.*

**GOOSEBERRY SEEDLINGS.**—I THINK your correspondent at page 131, need not be dissatisfied with the result of his experiment. To have raised two really new and excellent varieties is no small success. I would, however, recommend any who wish to distinguish themselves in this line, not to trust to chance seedlings, but to artificially fertilise. Some years ago, I took Whitesmith as a female parent, and fertilised with Hedgehog and Pitmaston Green Gage. Four plants of each were raised. Those from Hedgehog were coarse and inferior to both parents. Among the other four were

two good Yellows—one remarkably good, which has been preserved, but, unfortunately, it seems a bad bearer. So my own success is not great, but I think I took the right road.—S. B.

## THE MIRABELLE PLUM.

"Once upon a time," when Louis Philippe was king, I happened to be strolling about the *potagerie* (kitchen garden) at Versailles, taking notes and making the best use of my eyes. Among other things I was much struck with the enormous quantities of the above-mentioned kind of Plum. Large basketsful were arranged in a row, and more still being gathered. I, thinking the king a wise and economical ruler, inquired if they were not for market, but was promptly told that they were highly valued by the royal family, and were used for compôtes and preserving to an enormous extent. I did not then appreciate them, for uncooked they were dry and, to a certain extent, flavourless. This pretty little Plum must not, however, thus be judged, for preserved whole, without sugar and without water, in bottles, it acquires the most delicious aroma ever smelt or tasted, and this is more powerful when the fruit are placed in a pudding or a compôte and served up hot. When made into a jam without their stones they are also most delicious, the flavour being so rich and delicate. In the neighbourhood of Metz it is called *Mirabelle de Metz*, and is grown to a great extent at Nancy, and throughout the east of France.

The tree seems to require a rather dry climate, and would doubtless succeed well in the calcareous soils of the east of England. The last summer being dry and warm the crop here was abundant, and I never remember seeing anything in fruit culture more interesting than the pretty bush-like trees, not larger than a good-sized Gooseberry bush, literally covered with their bright golden fruit, spotted with red, oval, and about the size of small Damsons.—T. R.

## GAY ORCHIDS, AND ORCHIDS FLOWERING IN WINTER AND SPRING.

"B. H." would be much obliged by being informed which are the twelve best and gayest Orchids, and also by having a short list of those which flower in winter or early spring.

WHEN one essays, in compliance with the wishes of a correspondent, to name "the best and gayest twelve" Orchids, out of, perhaps, a thousand or twelve hundred species in cultivation, he finds it needful to guard himself by two caveats. First, he cannot have a personal knowledge of all the species grown, particularly the more recent introductions; secondly, he can give only his own opinion; and in a matter of taste so arbitrary as the comparative beauty of flowers, others may very legitimately demur to his conclusions. I think the following dozen may be named as the very *crème de la crème* of this glorious order; though it would be easy to make up the number to twenty with scarcely a diminution of the claim. The letters prefixed indicate that those kinds flower in the colder period of the year; L, late in autumn, occasionally protracted into winter; w, November to February; e, early, say March or April.

*Aerides Fieldingii*, or *maculosum*, or *nobile*.—These three are, perhaps, the finest of this lovely and fragrant genus.

L. *Cattleya labiata*.—The great size, and the rich crimson purple of the lip, distinguish this species.

*Dendrobium Deconianum*.—The flowers are large, of a rich cream colour, purple tipped, with two orange clouds on the lip. A noble and lovely species.

D. *Falconeri*.—Flowers very large; the sepals bluish white, petals and lip cream, purple-tipped; the lip has a deep purple throat, margined with orange. A glorious species, much exceeding even the preceding.

*Lælia purpurata*.—Flowers very large; sepals and petals pure white, or flushed with rose; lip ample, rich crimson-purple. A worthy companion to *Cattleya labiata*.

w. *Odontoglossum Pescatorei*.—Makes a lovely spike of broad flowers, white, with the crest yellow.

O. *phalanopsis*.—White, except that the central area of the lip is of a fine crimson. Flowers on twin spikes.

w. O. *triumphans*.—Branched spikes of flowers; the sepals and petals yellow, barred and spotted with crimson; lip white, edged with dark rose. Magnificent and rare. *Hanc non ridi*.

*Phalenopsis amabilis*.—The charming white Moth-Orchid of the Indian Isles.

*Saccolabium guttatum*.—Throws out long, compact, pendulous, cylindrical spikes of small flowers, white splashed with purple.

L. *Vanda carulea*.—Flowers large, pale lilac-blue, in a loose spike.

w. *V. suavis*.—Flowers porcellaneous; white spotted with purple, unspotted beneath. Noble and handsome, both in foliage and bloom.

As "B. H." says nothing about price, I have not considered this element in making the above selection; but as some of those named bear excessively high prices, I subjoin the names of a few other species, all truly desirable,

but obtainable at more moderate rates: some, indeed, are very cheap.

e. *Aerides odoratum*.

e. *Cattleya Mossiae*.

w. *Epidendrum vitellinum*.—A noble spike of orange-scarlet blossom. A greenhouse species.

L. *Lælia Perrinii*.—Sepals and petals of that lovely light rosy purple, which is almost peculiar to Orchids; lip deep crimson-purple.

w. *Lycaete Skinneri*.—Flowers very large; varying much from waxy white to crimson. A greenhouse species, almost hardy.

L. *Odontoglossum grande*.—Flowers very ample, yellow clouded with dark brown, tiger-like.

*Onidium excavatum*.—A fine panicle of broad flowers, rich yellow with a few red spots at the bases. Perhaps the noblest of this vast genus.

w. *Sophranitis grandiflora*.—A minute block-plant, with large flowers of crimson scarlet. A lovely gem, cultivable in the greenhouse.

The following ordinarily flower in winter and early spring, besides those already mentioned:—

## FROM NOVEMBER TO FEBRUARY.

*Angraecum bilobum*  
*eburneum*  
*sesquipedale*  
*Ansellia africana*  
*Arpophyllum spicatum*  
*Barkeria elegans*  
 Skinneri  
*Bletia Shepherdii*  
*Brassavola glauca*  
 Digbyana  
*Brassia caudata*  
*Burlingtonia amoena*  
*Calanthe vestita*  
*Cattleya maxima*  
 bicolor  
 Walkeriana  
 Warscewiczii  
*Cœlogyne cristata*  
 Gardneriana  
 media  
*Cymbidium eburneum*  
 giganteum  
 Mastersii  
*Cypripedium insignis*  
 purpuratum  
 venustum  
*Dendrobium chrysoxanthum*  
 fimbriatum  
 heterocarpum  
 macrophyllum  
 moniliforme  
 nobile  
 Pierardii  
 pulchellum  
 speciosum  
 Wallichianum  
 Lowii  
*Epidendrum fragrans*  
 rhizophorum  
*Gongora maculata*  
*Grammatophyllum speciosum*  
*Ionopsis paniculata*  
*Lælia acuminata*  
 albida

*Lælia anceps*  
 autumnalis  
 peduncularis  
 furfuracea  
 superbiens  
*Leptotes bicolor*  
*Limnæa rosea*  
*Lycaste Deppei*  
 cruenta  
 macrophylla  
*Miltontia cuneata*  
 Karwinski  
*Odontoglossum maculatum*  
 membranaceum  
 pulchellum  
 Rossii  
 biconense  
*Oncidium Barkeri*  
 bicallistum  
 Cavendishianum  
 divaricatum  
 flexuosum  
 incurvum  
 lenocchilum  
 oblongatum  
 unguiculatum  
 Forbesii  
 oratorrhynchum  
 varicosum  
 Phajus Tankervilleæ  
*Pleione maculata*  
 Wallichiana  
*Schomburgkia crispata*  
*Stanhopea eburnea*  
*Sophranitis cernua*  
 violacea  
*Stenorchilus speciosus*  
*Trichocentrum fuscum*  
*Trichopilia tortilis*  
 Warren Lindniana  
*Zygopetalum orinatum*  
 brachypetalum  
 Mackayi

## IN MARCH AND APRIL.

*Arpophyllum giganteum*  
*Bletia patula*  
*Burlingtonia fragrans*  
*Camarotis purpurea*  
*Cattleya amethystoglossa*  
 Skinneri  
*Chysis bractescens*  
*Coryanthes speciosa*  
*Cypripedium caudatum*  
 hirsutissimum  
 villosum  
*Dendrobium aggregatum*  
 anosum  
 Cambridgeanum  
 crepidatum  
 Dalhousianum  
 densiflorum  
 Farmeri  
 fimbriatum  
 lituiflorum  
 pruinatum

*Epidendrum aurantiacum*  
 bicornutum  
 crassifolium  
 Hanburyanum  
 macrochilum  
 Stamfordianum  
*Lælia cinnabarina*  
 flava  
 majalis  
*Leptotes serrulata*  
*Odontoglossum Warneri*  
*Oncidium ampliatum*  
 sarcoides  
 sessile  
 sphacelatum  
 Phajus Wallichii  
*Saccolabium miniatum*  
*Trichopilia suavis*  
 Vanda cristata  
 insignis  
*Zygopetalum rostratum*

Perhaps the above will scarcely answer to "B. H.'s" request for "a short list;" but it is easy to select, and I could not well omit any known to me as meeting the conditions.—P. H. G.

## FAILURE OF HYACINTHS IN GLASSES.

My Hyacinths in glasses have given up growing. They did very fairly at first and have excellent roots, but the leaves are only about 1½ inch long, and the flower-spikes, only half protruded, are beginning to burst into flower. I have changed the water several times, using sweet rain

water, and put a piece of charcoal in each glass, but the water soon becomes offensive, smelling strongly of sulphuretted hydrogen. The glasses have been and are kept in the window of a warm room by day, and in a warm corner by night. Crocuses in pots under the same conditions have come into flower.—V. G. C.

[Failure of Hyacinths is a common occurrence this year, and we believe that it arises from the bulbs being taken up in Holland before they have been perfected, in order to supply the very early demand for them in this country. We fear that you cannot aid your Hyacinths. Try the effect of adding one drop of spirit of hartshorn to the water in each glass. Change the water every week, adding the same small quantity of the hartshorn to the fresh water.]

### HEATING A SMALL CUCUMBER-HOUSE.

BEING a poor man, with every minute of the day occupied in business, yet being passionately fond of flowers, and horticulture generally, I do manage by getting up early, and going to bed very late, to carry out Tom Moore's advice, "that the best of all ways to lengthen our days, is to steal a few hours from the night;" finding, also, some truthful consolation in Longfellow's words—

"If you want a thing done, you must do it yourself, John."

So much for preamble.

In my spare mornings and evenings last summer I built myself a small house, which you would designate "a pit," I think. I bought your "Heating Manual," and "Green-houses," &c., and capital little books they are, but I cannot find exactly what suits my case in heating by gas, as I want to do. Well, this little house, allow me to call it so, is 18 feet long, 4½ feet wide (don't laugh), 4 feet to the glass in front, and 7½ feet to the glass at top. I have sunk the path 1 foot or more to get head room. I take 18 inches off the width for path, as though I yield to no man in respect for crinoline, I do not wish to see it in my little place, albeit I am, what Miss Mitford called us all, a *vagabond*, alas! a bachelor! Well, 4½ feet will be 54 inches, 18 from that will leave 36 inches for border in front. Now, in this space 18 feet long, and 3 feet wide, last June I put a little half-spent dung from my frame, some loam and leaf mould on the top, and put in six Cucumber plants, strong ones, and six Melons. I trained them up the roof, and cut scores of Cucumbers, and fifteen Melons, ripe, and pronounced of good flavour. This was to the astonishment of my friends who laughed at my enthusiasm at first. Now, I want to heat this little place. I am so engaged as to fear that the fire of an ordinary fire, &c., would be neglected, and I have a great fancy for gas. I noticed recently what strikes me as a capital little boiler, and I think I can have one made of galvanised iron by my neighbour the tinker, much cheaper, and as effective. Please say if earthenware pipes (3 or 4 inch, which?) would do, and where they can be procured, what length, and would one-inch or two-inch lead pipes do to connect with the boiler? One pipe to run along in front close to the ventilator for top heat, the return-pipe to go, covered with clinkers, &c., below the soil. I want to use this house early in spring for propagating, raising seeds, &c., so I should not want to begin Cucumbers very soon. If I have an air-pipe in the highest part of the flow-pipe, there will be no need of an air-pipe in the boiler, I suppose. If the enclosed plan will heat 50 feet of four-inch pipe, and my piping will only be about 36 feet, so much the better for me. One more query I must trouble you with, and that is the best kind of Cucumber to grow in a house. Last year I had what should have been Ayres' Black Spine, but it was a white one. The Melon was Bromham Hall, but out of the six plants there were two quite different from the others.—*CUCUMIS SATIVUS*.

[We congratulate you on your success. The cutting so many Cucumbers, and fifteen good Melons from a low house or pit 18 feet long, 4½ feet wide, 4 feet to the glass in front, and 7½ feet to glass at back, is proof that in such a house you have done well. The sinking of the 18-inch pathway to obtain more head room was a good idea, and we presume you used board or brick on edge to keep the three-foot bed in front from your pathway, so as to keep all clear for your-

self, if you debar the dear girls and their crinoline. Now, you want to heat this little narrow place, and wish to have bottom and top heat, and to do it with gas, which for your circumstances has many advantages, as by regulating the tap you can also regulate the power of the gas jets, so as just to keep the water warm. But for this we believe the simplest plan would have been a small furnace outside, and a small fire some 4½ inches wide, inside measure, to go below your bed, and return by the pathway to the chimney. Or if you merely wished top heat, a small gas stove, or a small brick Arnott's stove would have answered every purpose. To make either of these answer for both kinds of heat, however, would require a chamber round them, and more trouble in the management. On the whole, then, we approve of such a little copper boiler as you allude to, as made by Mr. Lynch White, and if the water is not heated above 170° or 180°, there will be no necessity for the iron jacket being placed round it. No doubt your neighbour will make one of galvanised iron cheaper, but it will not last so long. We see no necessity for the air-tap in the boiler. If you have a small supply cistern at the highest point of your flow-pipe, that will be quite sufficient.

We would not advise you to have earthenware-pipes in such a nice little house, but to have two nine-foot metal lengths for top heat, and the same for bottom heat. You will thus do with about three supports for your pipes, one at each end, and one in the middle. You would want more supports for earthenware, and if a leak took place below your clinkers, &c., it would be difficult to get at it. With nine-foot lengths, which, if three or four-inch will cost from 2s. 6d. to 3s. per yard, you need have no more than one joint in the middle of your house. We would not object to the boiler being 12 or 13 inches in height instead of 10½.

Now, as from what you say, we should judge you wish the matter to be as simple as possible, so that you and your neighbour may do all the work required, this is how we would advise you to do. Get your boiler of strong galvanised iron if you like, or even block tin, only it will not last so long. Set the boiler so far raised above the floor that you can turn a rough broom of hair inside frequently to keep it clean, and make sure that the smoke-opening, though small, is kept clear, that the gas-smoke may escape out of the house instead of being sent back again. The space of outlet should, however, be small, and the throat should have a plate across, to send the heated air back again like a damper, with two other small holes at the side to let it escape. Then the next thing is to have a flange, or a hole made at top and bottom for a one-inch lead pipe to be firmly soldered to each place, for connecting the top and bottom pipes for heating. These will heat quickly if made of galvanised iron or tin, but they will not last a lifetime like the cast iron ones. Now, as already said, we will only have two joints in these pipes, and that is in the middle of the house. At both ends of the house we will use wooden plugs for the ends of the pipes, and through these we will take the connecting lead pipes. Thus for the flow-pipe, we will set it in its place, make a plug—say 6 inches long, with a hole in the middle of it scarcely an inch in diameter, and through that, and fastened securely with white lead, we will place the end of the inch flow-pipe from the boiler; the return-pipe will be done the same way. Then we fasten the joints of the pipes in the middle, seeing that they properly fit, and after putting in some tow and red lead at the sockets, we fill up firmly with the same, using a thin spatula and a mallet, or even Portland cement, pushed firmly in when as tough as it can well be made. Then at the further end, we use a similar plug to each pipe, and connect them together with a similar piece of lead pipe. Thus without bends, curves, or more regular joints than two, the means of circulation are complete.

But you have as yet no water in the boiler or pipes, and have left no means for letting it in. We have thought, however, of all that. We would in placing the flow-pipe of nearly 18 feet make the farther end some 3 inches higher than the end next the boiler. At that highest end we would drill a hole—say 1 inch—in the pipe, behind the plug, fix a one-inch pipe into it securely by one end, and the other end securely into the bottom of a small cistern, to rest on the pipe—say 12 inches by 15. Wood will do as well as anything, or zinc or galvanised iron. Here you put in the water slowly,

and when full this cistern will always tell you how the pipes are supplied, and will serve as an air-outlet as well. We prefer filling such a place slowly, that the air may escape as the water takes its place. The lower pipe should descend as gradually to the boiler as the upper one rises to it. One remark more as to this lower pipe. The higher it lies in the bed—that is, the higher above the bottom, aye or even the top, of the boiler, the better it will act. And, again, if the bottom of the bed is concreted so as to hold water, at least to a degree, and the covering of clinkers is so thin as to be near your plunging-bed, or growing-bed, the more will the pipe tell as a promoter of bottom heat. It is true that heat will rise, but it is equally true that if such a pipe be covered with a foot of rough rubble, the heat will be in a great measure confined to the rubble, especially if this is placed very open, and there is no admittance of air to these openings. If a few small openings from the pathway of the house are in connection with these openings, the heat will ascend more freely. If the material become very dry, or the bottom of the bed be caked with dryness, the heat will not ascend well; but either in your bed for cuttings, or for Cucumbers, you can leave a few small drain-pipes standing up, one end above the soil, and the other among the clinkers, and pouring water in will cause the heat to rise more kindly and uniformly. These tiles may be plugged or opened as deemed necessary. We shall be glad to hear how you manage and succeed. Of Cucumbers, Carter's Champion, Munro's Rabley, and Sion House Improved, are good for such a house. Bromham Hall is a good Melon; Turner's Gem, and Golden Perfection, are also good.]

#### COMMENDATIONS AT THE CRYSTAL PALACE ROSE SHOW.

Will you allow me to suggest that it would, I think, give great satisfaction to exhibitors at this Show if good stands of flowers not in the prize-list were highly commended or commended, as is done at poultry shows? We cannot all take prizes, but I must say that it is not satisfactory, after all one's trouble and expense, to be altogether unnoticed. The expense of a few cards would be so trifling, and the gratification given to exhibitors so great if this plan were adopted, that I am surprised no one has thought of it before.—P.

#### SUCCESSFUL VINE-LIFTING.

HAVING read in your excellent Journal an article on Vine-lifting, in answer to a correspondent signing himself "J. H., Nairnshire," and as facts in gardening are usually worth recording, I will state my own experience on the subject.

In a lean-to vinery of about 30 feet in length, lofty and well built, the Vines were planted about fifteen years ago, and bore well for several years; but owing to over-cropping and high feeding with manure water (than which nothing spoils a Vine-border sooner), they gradually dwindled and suffered so much from mildew, shanking, &c., that it was necessary to do something by way of remedy. My employer suggested cutting the old Vines out and replanting with young ones, but not liking the idea of doing this without giving them a chance, I obtained his permission to give them one more year, in which, if possible, to regain their character. I at once set to work to take out the old border and re-make it. I had every handful of the old soil taken out to the depth of 5 feet, and to my consternation found that the few roots of the Vines had gone straight down 5 feet through the border, and after making their way through the drainage had penetrated into the subsoil some 3 or 4 feet farther, which made me almost despair of doing anything with them, as the only roots that I could preserve were about the thickness of a man's thumb, and about a yard long. I worked away and made a new border of the usual materials, having first properly drained it, but this time only 3 feet deep. The Vines were replanted on the 23rd of December, 1863, which, I believe, according to the usual theory on the subject, is the wrong time, but the result proved that this rule is not without exception. Let me add, however, that I was obliged to do it then or not at all. The border was then covered up with 2 or 3 feet of stable

manure, which upon examination a short time afterwards, I found had set the roots working nicely, in fact, the border was like a mild hotbed. The Vines, which were formerly trained two to a light, were every alternate one cut down to the front sash, and those remaining close-pruned on the spur-system, and painted with a mixture of soft soap, sulphur, &c.

The Vines were gently started in the beginning of March; they broke well and strongly, and produced 116 bunches of well-flavoured and well-coloured fruit, the bunches averaging 1½ lb. each, being more than double the crop of the previous year, and they were quite free from mildew all through the season.

The sorts are Chasselas Musqué, Sweetwater, Wilmot's Black Hamburg, and Muscat Hamburg, and I must not omit to mention, that the house has to do duty as a warm greenhouse. The Vines have made capital strong wood this season, perfectly clean, and, in fact, have done all that could be desired of them.

I have detailed this experiment in the hope that it might throw some light on the cause and cure of mildew, or, at any rate, if it only cheer some brother in distress and prompt him to do as I have done and find a remedy, I shall be well rewarded.—BUENTWOOD, P.D.

#### WORK FOR THE WEEK.

##### KITCHEN GARDEN.

AFTER so much frost and snow as we have had at intervals during the last five or six weeks, the soil, where due attention was paid to trenching, ridging, and forking, may be expected to have received much benefit by their purifying and pulverising action, and to be now in a good condition for some of the principal crops. As we may now expect drying winds, less intense frost and more sun, no time should be lost in making good all deficiencies in autumn plantations of Cabbages, and getting in forthwith a new plantation of the strongest and healthiest plants to follow in succession. A small portion of seed of some good variety should also be sown in a sheltered corner, in order to have plants at command and that may be depended upon at the moment they are required. The space allotted for Carrots, Onions, Beet, &c., should be constantly forked up on suitable mornings, exposing to the influence of the atmosphere as much surface in as rough a condition as possible, in order to have it in good working order by seed-time, which is now fast approaching. *Cauliflowers*, make a fresh sowing in the frame, and look over the seedling plants that are up, also the seedling plants of Lettuces, &c., and sprinkle a little dry sand or dry earth amongst them, as they are very liable to damp off at this season; also thin them out if crowded, as nothing tends more than this to cause them to fog-off. *Celery*, make a small sowing in heat. *Parsnips*, now is a good time to sow the main crop in ground deeply trenched, with the manure at the bottom; it is a very useful vegetable, and none pays better for care in cultivation. *Potatoes* of an early sort may now be planted on a warm south border. Trenching and manuring may still be carried on. Let the edgings of walks be made good, and the gravel turned and rolled, fresh gravel being added where necessary. The side walks or alleys should have a good coating of coal ashes laid on; this is a good material for the purpose, as it does not form a puddle after a frost or in wet weather.

##### FRUIT GARDEN.

In carrying on the operations of trenching up fruit-tree borders it is advisable to examine the roots of luxuriant-growing trees, and remove some of the largest; it is better, however, to follow a regular system of root-pruning, because it enables us to keep the roots near the surface. Pruning and nailing must be completed without delay, and the interruption in the work, occasioned by the late inclement weather, must be made up for by corresponding energy now.

##### FLOWER GARDEN.

Avoid all indiscriminate use of the knife in pruning. We would recommend cutting back the shoots of Moss and Provence Roses to three or four buds, because if not pruned in this severe manner the heads will soon become straggling and weak, and cease to produce vigorous flower-buds. Hybrid Provence, French, Hybrid Bourbons, Damask Per-

petuals, and Hybrid Perpetuals should have the strong shoots shortened to within six or eight buds from the bottom, removing all the small spray and cross branches and spurs which have produced bloom last season, leaving the shoots at regular distances. Hybrid China Roses are so impatient of the knife, that if pruned in the same manner as recommended for the preceding classes they will scarcely put forth a flower. The shoots ought by all means to be left nearly their full length, merely cutting off the tips of the shoots, and thinning some of them out where too thick. The Sweet, Hybrid, and Austrian Briars should be pruned in the same manner, and an abundance of bloom will be the result. To have a succession of flowers of the summer varieties it is only necessary to leave some trees unpruned till April, they will come in a fortnight later. In pruning cut close to the bud, the wound will soon heal over. Commence the pruning and nailing of Roses and climbers against walls. Complete all new work and improvements which have been retarded by the severity of the weather. See that Heartsease, Pinks, &c., in beds or borders are not thrown out of the ground by the late frost. If they are loose fasten them. Proceed with planting-out biennials as soon as the ground is in a fit state, and prepare a little ground in a warm corner for sowing Stocks and some of the best of the annuals for transplanting.

#### GREENHOUSE AND CONSERVATORY.

Orange trees in tubs or pots should be carefully examined in order to ascertain whether or not the roots are in a healthy state, and those requiring more room should be shifted at once. In many instances, however, it may not be possible to afford large specimens a shift: in that case remove as much of the surface soil as can be done without injuring the roots, and replace it with a mixture of good loamy turf, broken bones, decayed cowdung, and sand, and see that the balls of the plants are in a moist healthy condition. Manure water is of great service to Orange trees, and may be applied freely at all seasons, particularly when they are starting into growth. It is quite impossible to use the syringe to advantage in many conservatories, and under such circumstances when the weather is favourable the flowering plants should be removed to one end of the house, and the twiners, &c., given a liberal washing with the engine, which will also greatly assist in keeping the glass clean. This should be done before the twiners start into growth, as there will be no danger of injuring the tender foliage while the plants are in a dormant state. As the season advances give more air to the houses. See that suitable composts are ready under cover for potting and sowing seeds. Some of the hardwooded plants may now be propagated by cuttings where a gentle bottom heat can be kept up.

#### STOVE.

Young plants of *Aphelandra*, also of *Poinsettia* and *Euphorbia fulgens*, raised from short cuttings now, and kept growing in a cool part of the stove all the summer near the glass, will make nice dwarf-flowering plants by winter. The cuttings are to be rooted in moist heat. Many of the *Justicias*, *Eranthemum pulchellum*, and some of the *Begonias* may be treated in a similar manner; and all these will be found exceedingly ornamental in the winter months. *Eranthemum pulchellum* has fine blue flowers, those of *Justicia flavicoma* (or *Calytricha*) are yellow, *Begonia Martiana* is deep rose pink, and the *Euphorbia fulgens*, *Poinsettia pulcherrima*, and *Aphelandra cristata* and *aurantiaca* are of various shades of red and scarlet.

#### DUNG-PIT.

Of all the plants which delight in dung heat there are none which are so much at home in it as *Clerodendrons* and *Ixias*, and hence some nice stocky plants of each should be potted and placed under its influence at once. The former delight in a free open soil, consisting of loam, peat, and leaf mould, with a little rotten cow-dung and silver sand; and the *Ixoras* in pure turfy peat, with charcoal and gritty sand. If the plants are well rooted, give a liberal shift, but do not overdo them. In addition to these plants may be named *Dipladenia splendens*, *Cryptoceras reflexum*, *Allamanda cathartica* and *A. grandiflora*, *Luculia gratissima* and *Pinciana*, *Gardenias*, *Schubertia graveolens*, *Stephanotis*, &c., and such softwooded plants as *Gesneras*, and

*Achimenes*. In the management of the pit keep a fine growing heat of from 60° to 70°. Shut up early in the afternoon, but open the sashes a little before leaving for the night.

#### PITS AND FRAMES.

Sow seeds of *Mignonette*, Ten-week Stocks, Cockscombs, Balsams, and many tender and half-hardy annuals.—W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

OUT of doors much as in previous weeks, the ground being too hard up to Thursday night to attempt doing anything. On Wednesday and Thursday we uncovered Cauliflowers, Radishes, Lettuces, Endive, &c., that were merely protected from the frost, and had been covered for eight or ten days. Peas on turves, Beans, &c., placed between rows of Potatoes in frames, were uncovered oftener, as the little heat below them would otherwise have caused them to spindle weak. Wednesday and Thursday were good days for uncovering what had been a long time covered, as though the air was mild, there was no sun, and the plants would be gradually injured to the light. After being covered a long time—say a fortnight or a month, it is as well not to give them bright sun all at once. Extremes of all kinds should be avoided. Young Cucumbers in frames, with little below them except tree leaves, are slightly drawn, as in the severe weather we could give them little air, and could only uncover part of the glass opposite the plants without reducing the temperature rather much. A few of these mild days with a little sun, will make them all right. Sowed a few more; it is always advisable to keep a few plants for succession.

Put up another bed for Cucumbers, to be in readiness, making the bottom of half-sweetened dung and leaves, and the top of sweet leaves. This is making the most of the material, the rank steam will become sweet enough before it passes through the leaves. We scarcely ever turn over a heap of fermenting material several times in the old-fashioned way, as that would lessen our limited supply, and send a great quantity of heat into the open air, which we would like to be used in giving some things a fair start. We also use few leaves in a heap of dung until the dung is heating and fermenting freely, as too much heat from the dung would waste the leaves; but in all cases where this rough-and-ready mode is followed, care must be taken to have 1 foot or 15 inches of thoroughly sweet fermenting matter over the surface of the bed. Such beds, made of material not too much decomposed, keep up a more regular heat, and for a much longer time, than from dung and general fermenting material too much decomposed. We make it a rule, however, to make our beds wide enough to be able to bank up the outside of our frames almost to the top, so that the heat of the enclosed atmosphere is a good deal derived from the boards or wall inside, instead of having to pass through the soil, &c., first, which gives some chance of burning the roots. This banking-up and protecting the outside of the bed with long litter or branches, renders fresh linings of little importance until the season is well advanced.

Here, on the question of *Linings*, we would with all due respect, say a word on pigeon-holed walls for pits for forcing, in reference to the answer to "Двоило," page 137. No doubt pigeon-holes are very useful, but when they are present, one of two things must be attended to—either the fermenting material for the linings must be sweetened before using it, or care must be taken that no steam from such linings can pass into the atmosphere, where Cucumbers, Melons, or other tender plants are grown. The latter may be done, either by having a secure-floored chamber beneath the bed, or flues, on the McPhail system, or by keeping the soil of the bed firmly secured against the walls above the height of the pigeon-holes. What we wish to say, however, is chiefly this, that several times we have wrought pits with solid walls by linings with very great advantage, and with great economy as to preparing the dung for other beds and frames.

One advantage of the solid-wall system is, that if you use ordinary care in giving air, no deleterious steam can pass into the place. In one case, inside, we made a nice little bed

of sweet fermenting material in the usual way, and in that case the linings were used to keep up the bottom and top heat. In another case, the inside of the pit was roughly filled, very openly, to the suitable height, with stones, clinkers, &c., a thin slate bottom put loosely over all, and on this the soil was placed. Some small drain-pipes every 3 feet or so, were fixed inside back and front, one end communicating with the rough chamber, and the other end opening into the atmosphere of the pit. This prevented what might have taken place from an enclosed non-conducting body of air, and to a certain extent kept the enclosed air of the pit in movement. Owing to changes, we do not work pits in the same way now—in fact, have none with linings; but the solid walls which we did work, were built in three ways. One of these pits had nine-inch piers opposite each rafter, the rest was single brick on bed, laid in first-rate mortar made with washed sand that made it almost as good as cement, and in this, opposite the centre of each light, a stout slate 1 inch thick, 3 feet by 2, was fixed in the front and the back wall. Given plenty of good fresh horsedung from the stable, and such a pit, unless in the severest weather, could easily be kept at a temperature of from 70° to 80°.

A second pit had nine-inch piers opposite the rafters, which were 4½ feet apart, and the rest of the wall was of 4½-inch work from brick-on-bed. This also was built with first-rate mortar, not lime and mud. Provided we had the material, we never had any difficulty in obtaining plenty of heat. The third case was a nine-inch wall. It had been pigeon-holed for Pines; but, as there was no heat but linings, it used to give us too much internal moisture in winter, and so we blocked the holes all up. In turning linings against such a nine-inch wall, we took care to keep the hot half-sweetened material next the wall, and the fresh, new material more at the outside; and frequently we have felt the inside of the wall in the morning, and found it as warm as a flue. In such a thick wall it would be necessary to have a wide lining in winter, and in mild weather extra heat could be neutralised by extra air.

Where there is abundance of fermenting material the nine-inch wall would do well enough, but on the whole we would much prefer the 4½-inch wall, or brick-on-bed, and the smallest possible joints, with the best mortar. In all these cases abundance of manure must be pre-supposed. In the cases in which we used such pits we banked them up pretty well to the wall-plate, and there was no want of fresh stable manure when wanted. We brought it and placed it round these pits at once, and thus made them the preparing and fermenting-heaps for making beds below frames, removing it as it became sweet enough for that purpose, and supplying fresh, but always leaving enough at the sides of the pit to prevent a sudden check from want of heat. We found this a very economical mode of sweetening the dung for other beds, where the least rank steam would be destructive; whilst, as respects these pits themselves, no steam could pass through the walls. The only thing that required care was to watch the direction of the wind in giving air, so that no rank steam should blow in at the opening. We hope our worthy coadjutors will excuse this statement, as we believe there are many cases where solid-walled pits, heated by linings, would be as useful as those with pigeon-holed walls, and in some respects less dangerous. Last season we were much grieved to see the wrecks of Cucumbers and Melons in such a pigeon-holed pit, belonging to an enthusiastic amateur. He had brought the mowings of his lawn to the lining; a crack, unobserved, had separated the soil inside from the wall of the pit, and up this the rank steam ascended, carrying ruin with it.

Gave more room to Dwarf Kidney Beans, sowed more took the chance of the thaw to take up more Sea-kale and Rhubarb, and put them in the Mushroom-house. Put, also, a few barrowsful of dung on a bed now preparing for Mushrooms, and cleaned and swept those bearing. We have constant proofs of the retentiveness of vegetable life. The last bed was pretty green with a crop of Oats. Now these must first have passed through the stomach of the horse, and then been pretty well heated in a heap before being formed into the bed, and still they grow freely. In moderation, we do not think they do much harm. If much covering is used that soon settles them. When a bed is backward, we prefer a little surface covering to giving much heat below the bed.

This covering increases the temperature of the air close to the surface of the bed, and after some experiments and much observation, we do not consider Mushrooms grown in the dark at all inferior to those grown in light. In one sense they often please better, as the buttons are generally so white.

*Ice Collecting.*—On Tuesday we had a rare day at this work, filling our ice-well to the crown, and passages as well. From the severe frost on Monday, the ice was not only fully 4 and 5 inches thick, but it was almost as hard as flints, and the breaking was no joke. In fact, we could not break it very much, only sufficiently so to obtain a lot of powdery matter to fill up all holes among the larger pieces, so as to exclude air. We believe that if such ice had been cut in blocks and carefully built together, with a little water run over so as to fill up every cranny and be well frozen, it would have kept better than with all our pounding and smashing; but we could not spare time for any such nicety. Even the breaking we gave told upon the arms and shoulders of the breakers. People who have the chance should try and store up a heap, as, independently of the luxury, many a useful life has been saved in the case of fevers, &c., by a timely application of ice. We could envy no owner the feelings that would lead him to demur for a moment to filling a basket in such an emergency.

In the course of time the covering of the dome of our well and passage has been reduced, and the earth that is left has been made like a honeycomb, by the combined efforts of rabbits and rats; but as soon as convenient we must add to the thickness of earth, and take means for preventing the future burrowing of all such vermin.

#### FRUIT GARDEN.

Out of doors little or nothing has been done. In-doors Strawberries in bloom have been placed in the best places; but those swelling do so but slowly in such weather. Regulated Vines; sprinkled those starting. Placed a foot or so of warm leaves next the ground on the first vinery-border, as the covering put on previously had become wet and cold from the snow soaking through it. Even though we removed a good deal of it on other places, we were glad to let it remain as the best of all protectors. It has thus saved vegetables and field crops very much. Sprinkled Peach trees just as the buds were opening. In the Peach-house noticed the ants very busy on one part of a tree, and feared that all was not right; and true enough there were two or three patches of our old enemy the brown beetle. We at once dusted all we could see with hellebore, and in a few hours washed the place where we saw them with strong soft soap water, and again with Gishurst. We did think we had entirely destroyed them, and were much annoyed at their re-appearance. We washed the whole of the woodwork and the trees with hot soap-water: syringed all woodwork, trees, pipes, &c., several times with the same at a temperature of from 160° to 170°, or even more; then we removed carefully about 1½ inch of the surface soil, sprinkled the surface of what was left with hot water, and then top-dressed afresh, washed the walls and painted the trees all over with Gishurst, tied trees, and filled the house with bedding Geraniums. Now, after all this care some perfect insect or some eggs must have escaped all our heated water and painting. We thought we had quite got rid of the worst insect ever we met with; and we must carefully watch for the slightest appearance of them, even of a single one, and give it no chance by its amazing fecundity to fill the place again. After such care we begin to fear that we introduce such enemies at times in our fresh soil and our manure waterings when taken from the dunghill. It would be a safe plan to boil the latter before using it when cool enough; but then, so few of us have such conveniences. We have forgotten to mention that we smoked this Peach-house well with tobacco and bruised laurel leaves before we washed it; and if not brought in, some one or more, or some eggs, must have escaped all our care. We have observed no more as yet, but these few if let alone would soon be myriads. In fecundity the green fly is nothing to them.

#### ORNAMENTAL DEPARTMENT.

Here the chief work has been potting and taking dried soil into warmer places. We have also cleared a pit of young plants of *Centaurea argentea* or *ragusina*, and pre-

pared it for cuttings, which cuttings, as *Verbenas*, &c., and many of the best tender annuals for out-doors we will now hurry on. For *Verbena* cuttings, &c., we will chiefly use half-circular drain-tiles and old zinc spouting, or troughs, as vessels. In two-feet lengths the latter make admirable vessels for propagating. A few holes in them do no harm. Be the old spouts 2, or 3, or 4 inches or more across, it matters not, they are alike useful. All we do to them is to procure a pole the size of the spout, cut it into round pieces an inch wide, and then cut each in two with a billhook. These two pieces just fit into the two ends, with a couple of tacks at each end. It is best to leave a quarter of an inch or so open at the bottom, as that with a little rough stuff at the bottom of the trough is all that will be necessary for drainage.

For general treatment of plants in greenhouse and stove, we must refer to previous Numbers. In such fickle weather, care should be taken to give fresh air, and chiefly at the top of the house, and in watering not to spill any on the floor. Whatever is spilled will evaporate, and in a frosty night be condensed against the glass, and most likely if a hot sun succeeds it will melt and fall like a shower-bath over the house. A little air given early will help in this matter. In fact, in frosty weather a little given at the top of the house early will prevent the necessity of giving much anywhere during the day.

**Mossy Lawns.**—We would just add one word on mossy lawns. We thoroughly agree that if you pull up most of the moss, you should also top-dress and sow, as stated in a late Number. We once pretty well cleared a piece with rakes, &c., and then dressed with some ashes and lime, but that was not enough. We ought to have top-dressed richly and sown the fresh seeds. The exposure of the roots of the grass, by the tearing away of the moss, let the frost and the cold take such hold as to kill the grass, and next season the piece was like part of a fallow field. But unless where the moss is disagreeably long and luxuriant, why meddle with it at all? No more grass lawn, however solid and clean, can be half so agreeable as one formed partly of moss, if you do not sink much in it. In the one case you may have such a comfort as you can enjoy from walking on the floor of a room covered with stout oilcloth. In the other case you may enjoy such a luxury as is presented by the springing elasticity of a thick soft Turkey carpet. When a lawn, too, is covered chiefly with short moss that keeps green in moderate droughts, it is much more easily kept than one of fine grass. We have known some of such thick mossy lawns that a skiff with the scythe a few times in the season was sufficient to keep in first-rate order. Destroy the moss by all means, if it is so objectionable; but if it is short and firm, and you like a soft, elastic, easily-kept lawn, "let well alone."—R. F.

## TO CORRESPONDENTS.

**VERBENA VENOSA ROOT-CUTTINGS** (*H. J., Bristol*).—The cuttings of the roots will, if you get them strong, bloom much more freely than plants obtained from seed.

**PLANTS IN A SPARE ROOM** (*T. B. A.*).—If we could look in upon you we would better ascertain what you chiefly required to do to your spare room, 13 feet long, 8 feet wide, and 6 feet high, to render it fitted for plants. You speak of your kitchen garden being made over the slates of your coal-house and pigsty. If your kitchen garden had been larger, or if you had ground to use as a flower garden, you might make it very attractive, and have vegetables earlier with the help of this spare room, whether you could easily heat it or not. If you designed to use it chiefly for flowers, or a few early Strawberries, &c.—in fact in whatever way, we would advise you to have your window of 10 feet long made not 5, but 6 or 7 feet in height, so as to have all the light possible, though 5 feet will do if you must abide by that height; but if so, we would place it so that the top of the glass was within a foot of the ceiling. Even then the first 4 feet would be the most valuable for growing plants of any kind, and the back part of the room would be best for storing many things in winter. When you tell us what you are most anxious to use such a room for, we will feel more than a pleasure in helping you if we can. We have no doubt the rabbits will do in the place proposed, but it will be advisable to let them have sods or earth to amuse themselves with.

**WHITE TOKAY GRAPE** (*R. H. C.*).—This is evidently the Vine you purchased under the name of the "Torquay." It requires heat, and its fruit is not highly favoured.

**FINE PICEA PINSAP** (*A Subscriber*).—We have been favoured with a photograph of one of the finest specimens of this conifer that we have ever known in this country. It is 42 feet in circumference round the lowest branches, which touch the ground, and is 14 feet high, and perfectly symmetrical. It is growing in the grounds of F. Brown, Esq., Farley Hill, Luton.

**LA CONSTANTE STRAWBERRY** (*K. M.*).—It can be obtained from any of the principal nurserymen in the vicinity of London.

**MUSSETT'S HEATING APPARATUS.**—Having noticed the complaint of your correspondent, at page 118, against "Mussett's Patent Hot-water Apparatus," I feel bound to state, in justice to the apparatus, that the one we have at this place has fulfilled every expectation. It was supplied by Mr. Mussett last October twelve months, and has been doing duty in a house 14 feet by 7. My neighbour was less fortunate with his at first, as it seemed determined to smoke and not make the water hot. We both condemned it as not fit for the task assigned to it. One day he lighted up and prepared for the usual results, but the apparatus worked admirably, and it was only then he found that the previous failure was all due to his own carelessness in not adjusting the lamps according to the printed directions.—H. Moss.

**CHAMOIS SKIN WAISTCOATS** (*A Subscriber*).—The so-called Chamois skin is no other than the common untanned wash-leather so commonly used for cleaning plate, &c.

**SEEDS FROM AUSTRALIA** (*J. E.*).—Of the seeds sent all will be better of being sown in pots, well drained, and then set in a sweet-hothed, and the plants hardened-off by degrees after they are fairly up. 1. *Leptospermum lanigerum*, a woolly-leaved plant, might do out of doors against a wall in the south of England after the plant was well established. 2. *Eurybia aculeata* is a white-flowered Aster or Daisy-like plant with prickly leaves. 3. *Rulingia farinosa*, a soft-leaved, small, evergreen plant, named after the botanist Ruling. 4. *Lasiopetalum ferrugineum*, a rusty-looking woolly-leaved plant with white flowers, requiring a good deal of heath soil in the compost to grow it well, and also particular drainage. 5. *Callistachys linearis*. The seeds had better be steeped in warm water for twelve hours before sowing, say 130°. It is a dwarf shrub, with narrow leaves and reddish flowers; seeds enclosed in a pod; peat and loam. 6. *Pomaderris lanigera*, a woolly-leaved plant with panicles of yellow flowers, requiring loam and peat. 7. *Eucalyptus cotinifolia*, corymbosa, or something like that. The whole family is allied to the Myrtles, and have many of them fine foliage. In the south of England they will stand out of doors. 8. *Creatia*, cannot make it out. 9. *Humea elegans*. Sow in heat, prick off, and then pot off, and pot on during summer and autumn. Keep in a temperature not below 45° in winter, and the plants will produce their feathery heads next season—that is, in 1866. 10. *Creatia sertena* we presume to be *Acacia serotina*—if so, steep the seeds before sowing. 11. *Melaenca uncinata*, a rather strong-growing plant, and nearly hardy in the south of England against a wall. 12. *Pultenaea daphnoides*. Steep the seeds. Neat shrub with small yellowish pea flowers. To oblige you we have given this running commentary to your list, and would just add as a hint to others who now and then send such lists of seeds: first, that these seeds of yours have either not been collected by a botanist, or that you have spelt his names very indifferently, as some of them we have been obliged to guess at. Secondly, that though some are singular in their foliage, we question if there is one of the principal seedsmen about London who would not supply for a trifle those twelve packets of seeds, and in a condition more likely to succeed from your sowing than in the case of those sent home in the ordinary manner from Australia. Last season we were offered a part of several such collections to try them, but we frankly said that we could not find room or time for them. One who was very pressing we told how one that was a long time our co-adjuter used to receive such packages with thanks, because it pleased the donors, and then quickly put them in the fire-place.

**STRIPPING GRAPE VINES** (*Perplexed*).—The seeming contradiction arises from deficiency of explanation. The syringing was intended to be recommended to cease from the time that the buds burst until after the fruit was well set, and then to be given once a week until the berries began to colour. At other times watering the paths, &c., will keep the air sufficiently moist. We know that Gishurst compound may be kept dissolved ready for use, but we are informed by the best authority that it is best to dissolve it at the time it is needed.

**SELECTING STRAWBERRY RUNNERS** (*J. G.*).—Mr. Fish says he often takes them as they come, but a number of experiments convinced him that the first runners made by the Strawberry became the strongest and best plants, and the second and third runners the most fruitful.

**EUCHARIS AMAZONICA** (*St. Mellon*).—Without seeing the bulb we cannot give an opinion as to whether it will revive. Treat as is directed in our last Number, and it will soon give evidence either for or against itself.

**BOOK** (*A Young Gardener*).—To instruct you in drawing, such as a gardener finds advantageous, Loudon's "Self Instructor" will suit you. It was published by Messrs. Longman. Any bookseller can ascertain the price for you. (*Inquirer*).—Johnson's "Farmer's Encyclopedia," published by Messrs. Longman, will suit you.

**SKIMMIA JAPONICA AND PHOTINIA SERRULATA** (*F. M. J.*).—The *Skimmia* is a low shrub, not suitable for a wall, but nevertheless fine for shady places. It would do well in a north aspect, but is a rather slow grower. *Photinia serrulata* will do for a wall, but should have an east or west aspect. It may do fairly on a northern one near Gloucester, but we should prefer Iries. The flowers are white, and resembling those of the Hawthorn. They are interesting, but not particularly conspicuous; its chief attraction is its evergreen foliage.

**COMPOST FOR FERNS** (*J. J. J.*).—You could not have a better compost than that to be formed of your materials, loam, cocoa-nut fibre dust, charcoal dust, and silver sand. If yours be the cocoa-nut fibre dust, and not the dust, it is not good. The dust is like mahogany sawdust. The proportions of the above materials for Ferns may be half cocoa-nut fibre dust, a quarter loam (turky yellow loam is best), and the remaining quarter equal proportions of charcoal and silver sand. Such a compost will do well for *Benegas*; and there are few plants that would not do well in it.

**REPOTTING CAMELLIAS** (*Idem*).—Pot them in the beginning of April into pots a size larger, but do not give a large shift. Drain the pots to one-third their depth, and place over the drainage the rougher parts of the compost. Prepare a compost of peat two-thirds, turfy loam one-third, with a free admixture of silver sand. In the absence of peat cocoa dust (but be sure that it is dust, not fibre, for that is unsuitable) may be substituted for it. Turn the plants out of the pots, carefully remove the drainage, and pick away the old soil from between the roots with a pointed piece of wood, being careful not to injure the roots. Pot rather firmly, but not very hard, and with the collar of the plant slightly elevated in the centre of the pot. In potting be sure no vacant space is left between the ball and the sides of the pot. The soil should be worked down with a flat piece of wood, like a label in shape, and a gentle tapping of the pot on the potting-bench will help to fix the soil and fill up any cavities.

**PRIGGING-DOWN ROSES—POTTING FOR EARLY FORCING (G. B.).**—They are layered in the soil, and root freely from the stem of the shoot without the slanting cut as in layering shrubs. We have layered them both ways, and we like them better without than with an incision, as the shoot is liable to break when cut. The incision also impedes the sap flowing into the shoot, and causes a multiplicity of shoots in the centre of the plant. If you want the shoots to root and form separate plants, an incision would facilitate their rooting. The best time to pot Roses for early blooming is early in September.

**ALOCASIA METALLICA CULTURE (An Old Subscriber).**—Turfy peat one-half and the other half turfy light loam and leaf mould in equal parts, with a free admixture of silver sand, will grow it well. Drain the pot well. It requires a night temperature of 60° in winter, and from 65° to 70° by day, and when growing, or from March to October, a temperature of from 65° to 70° by night, and 80° to 90° by day. It requires a moist atmosphere when growing, a plentiful supply of water at the root, but not so as to make the soil sodden, and in winter enough to keep the soil just moist, very little being needed at that season.

**LIQUID MANURE, PREPARING AND APPLYING (K. D. T.).**—Perhaps the safest of all liquid manures is that formed by dissolving 2 ozs. of Peruvian guano in a gallon of soft water twenty-four hours before applying it. This is the proper strength for watering plants which have been planted out. One ounce to a gallon of water is quite strong enough for watering plants in pots. The drainings from the stable are a very valuable manure, but require caution in using. They should be diluted with six times their volume of rain water, but if partly diluted through water running into the tank they will only need to be made weaker. If diluted, so as to be about the colour and thickness of unfermented beer, the liquid will not be too strong for flowering plants in pots. All plants, with the exception of Heaths, Azaleas, and plants grown in peat, may be watered to advantage with liquid manure at every alternate watering; but to none should it be given until the plants are growing freely, and the pots filled with roots at least at their sides. It must be discontinued after the plants bloom.

**VINERY-BORDER AND HEATING (A Young Gardener).**—Your Vine-border of 3 feet in depth will give you room for a foot of rough rubble at the bottom. We approve of all that you propose. When you speak of walls of single brick with piers do you mean walls of 4½ or 9 inches thick? We would certainly prefer 9 inches. A small or medium-sized boiler will do. A conical one fed from the top will be easiest managed. For the vinery we would have three pipes in front, if to be forced early four pipes, and two pipes below propagating-bed. It would be well to make that into a span-roofed pit with small moveable sashes, or little glazed frames on each side. The heat then would be proportioned to the closeness maintained. These glasses may either be loose or hinged at the apex. We prefer the former, as they are so easily moved. For the span-houses, as it seems likely you may use them for different purposes, we would have two four-inch pipes all round, except at the doorways.

**LAYING-OUT A ROSERY (M. C.).**—It is quite a matter of taste as to whether a rosery should be made with grass divisions or with gravel paths. The latter for a large rosery we would decidedly prefer, as you can walk on them in all weathers. We will criticise any plan, but decline giving one. Meanwhile we would direct your attention to No. 2 plan in the "Flower-garden Manual," which you may have from our office by post for 5d. To improve such a figure we would lessen the size of the central oval, and thus enlarge the size of the four figures round it; but much more artistic plans may be adopted. A very simple and elegant plan for such a piece of ground, 48 feet by 148, would be a circle or oval in the centre, and quarter moons round it in succession to each end, and then a row of posts 12 feet high all round, with chains between for climbing Roses.

**VENTILATING SMALL GREENHOUSE (N. W. M.).**—If the ends of your small hipped lean-to house are of glass we would have a ventilator at each end at the apex, just below where the front roof and the short hip meet—say a triangle with a base 2 feet long, and a perpendicular in the centre of that base of 12 or 13 inches. A piece of wood 2 inches wide going up there would do for hanging two ventilators to, which you could open as needed. If you do not adopt our plan we would make two ventilators, as you propose, beneath the coping of the back wall.

**LOBELIA SPECIOSA SEED SOWING (James N.).**—To succeed it is necessary to sow the seed in gentle heat early in March, and when the plants are large enough to handle prick them off 2 or 3 inches apart in pans, continuing in heat until the plants root freely, then harden off. We fear you will not command heat enough in your dwelling-house to have them sufficiently forward for planting out to flower well the same season. We find it requires pushing to do this.

**ARRANGEMENT INSIDE A GREENHOUSE (T. C. H.).**—In your lean-to house, 8 feet high at back, 5 feet high in front, and 8½ feet wide, we do not think you could do better than have your proposed wide stage or shelf of 18 inches along the front—say 27 inches from the ground, then a pathway of 2½ feet; then divide the space behind into three or four tiers of shelves—say the front one 2½ feet from the ground, and the upper one 2 feet from the glass. This would enable you to keep and grow a considerable number of dwarf plants not much above 2 feet in height. If you wished for taller plants you could have a walk down the middle of 2½ feet, and a flat platform or stage of 3½ inches on each side. This would secure more head room. The first plan would be best for numbers of small plants. The second would do for taller ones, and be more simple.

**AMARYLLIS FOR A STOVE AND GREENHOUSE (J. S.).**—The Habranthus group of Amaryllids are the best and easiest managed for the purpose. They require less trouble and heat in winter than the Eucharis amazonica (see page 163), but if they have a lift in spring they bloom better and earlier in winter.

**SHADING A GREENHOUSE (Idem).**—The best material is stout canvass, and it is a great protection in winter. Frigi domo as a lighter material answers well. Strong size with the least whitening answers well for summer. Shades constantly in use soon wear out. We believe double glass would be better.

**PEARS.**—There is an omission in my Pear article which makes St. Michel Archange one of the three Pears not yet fully proven. Barbe Nelis should come in after St. Michel Archange. Barbe Nelis, Avocat Nells, and Iris Grégoire are the three believed to be good.—W. F. RADCLIFFE.

**NAMES OF FRUITS (E. F. D.).**—1, London Pippin; 2, Winter Pearmain; 4, Dutch Mignonne; 6, Winter Pearmain; 8, Colonel Vaughan's. Others not recognised.

**NAMES OF PLANTS (R. P. B. Kerry).**—Your Mosses are—1, a Tortula; 2, Polytrichum banum; 3, Bryum; 4, Tortula muralis; 5, Trichostomum polyphyllum; 6, Hypnum praelongum; 7, Bryum punctatum; 8, Hypnum proliferum.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### THOUGHTS ON POULTRY SHOWS.

THE list of forthcoming events in "our Journal" has become "small by degrees and beautifully less," telling most of us that the season of rest has arrived, during which we must brace ourselves up for the fresh campaign. I hope that as exhibitors will probably do their best, committees will strive to do theirs. "Rest and be thankful" does not suit us poultry-fanciers. Sometimes it appears to me that the type of a prize schedule of a show is unaltered from year to year, kept ready, cut and dried for the next meeting, no addition, no improvement made. I have been disposed to think this, even in so good a show as the now defunct Crystal Palace Exhibition. Schedule-framers appear to fancy they have arrived at perfection. We are all interested in the success and stability of shows, and if I therefore string together a few thoughts, others may be able to add theirs.

We are tolerably agreed that they succeed best as adjuncts to agricultural meetings. We are not quite so agreed that the classes in minor shows should depend on the locality, myself being disposed to think that if there are classes, exhibitors will fill them. There is no question that "grand" shows should contain classes for varieties of all breeds in any way moderately kept, and in some varieties to a greater extent than at present. My previous analysis of entries has proved this with regard to Brahmans, and I may here state, *en passant*, that although at Bradford a class for Brahmans was added very late in the day, it filled very respectably, nearly equaling the Dorkings, although they had a silver cup temptation, and greatly surpassing Spanish and some of the other breeds. I may just say, by-the-by, as I see a reply to Mr. Leworthy, in one of the late Numbers of "our Journal" from "our Editors," stating they remain of the same opinion still as regards this breed, that the discussion carried on in these pages has not had a similar effect on others, and that I have received a letter from a gentleman who happened to know my *nom de plume*, in which he says that the discussion has completely convinced him of the distinct character of the Brahma, and it will be agreeable to Mr. Leworthy to know that his communication had a great deal to do with the decision.

In framing rules I would suggest that the time between the show and the last day for entries is often unnecessarily long. In the largest shows a fortnight would appear to be quite sufficient, and it is unfair to other exhibitors to accept entries after the date. This, I fear, is often done; at any rate, the same number occurring twice in a catalogue with \* attached, and always to the same exhibitor's name, is suspicious. I believe that if the time of entry were of shorter duration more entries would be received, as it is difficult to say one month beforehand what it may be in our ability to do.

Further, I think that exhibitors would increase in number if committees showed them a little more courtesy. I am not saying too much when I write that the exhibitors are the most important part of the affair, and that without exhibitors we can have no shows. It is, therefore, a matter of importance to keep this class in good temper. There are several little matters which would help to do so, and which I now throw out as suggestions to committees.

Firstly, why not let it be a rule that with the labels a ticket of admission, not transferable, should be sent. Very often it would not be used, still it would give a kindly feeling towards the show in question to find you are not forgotten.

Secondly, I think that as soon as possible after the opening of the show a catalogue and prize list should be forwarded free to each exhibitor. Committees will say, "This is one of the items by which we hope to make money." Granted, yet it should not be out of the exhibitors, many of whom have had nothing but expenses. I have often thought that in printing catalogues, as we occasionally see them, a great deal of money and paper is wasted. Take the Brighton catalogue as an example. In other points cata-

logues sometimes have not sufficient printing. Take the "any other variety class," how often are the names of the birds omitted? This must be the fault of either the secretary or the exhibitor. If the former, he ought to be blamed; if the latter, he ought to be disqualified for incomplete entry.

Can any plan be devised for putting a stop to painting legs, &c.? Publicity does not seem to lessen it, as a name exposed by you some months ago is shortly afterwards found out at the same game again. Why not add a rule that all such pens should be forfeited to the committee? It would also be well and, I think, perfectly allowable for the secretary to intimate to the judge that certain pens would require a close inspection as a "painter" and "dyer" is the exhibitor.

"Selling classes" have become very fashionable. Have they answered the ends for which they were designed? I fancy not. I know that at one show first and second prize pens were claimed by their owners before the show was judged! in fact, entered for the prize, not for sale. I doubt if this can be remedied, a law preventing it could so easily be set aside by a friend claiming the pen; but it is worthy the consideration of exhibitors and committees. Possibly, as it is a class that pays very well for its extra prizes, committees will wink at this.

I do not think that managers of shows always carry out sufficiently their promise of paying every attention to the specimens. I have frequently before in your pages said that as regards food, they are too generous, but "every care" includes other matters, and the size of the exhibition pens is one of them. Baskets are bad, the open spaces let the cocks' tails protrude, and they are ruffled and broken. When baskets are used there should be some discrimination, so as not to give a smaller basket to Cochins than Bantams. Another point, often urged, and nearly as often forgotten, the placing all the entries in a class in the same light, is essential to please exhibitors.

Lastly, to bring my long yarn to a conclusion, I would make another suggestion that I think would greatly increase the entries. Gradually it has become an established rule to limit Game hens to one. Bradford has set the example in all the breeds. It was allowed that the specimens at this show were first-rate throughout. Had not this rule something to do with it? Many have a single very good hen. Again, the carriage is lessened, and now that some of the railway authorities seem to throw cold water on us instead of helping us, this is a great consideration. May Bradford in this respect find many followers! Then, perhaps, classes for "pairs of pullets" might be better than they now are.—Y.B.A.Z.

P.S.—I have just seen Mr. J. Wright's note as to Brahmas at Bradford. I gather that he had a catalogue, and threw it aside because it had no Brahma class. This, I think, was a mistake on his part; had he sat down and penned his reasons for not sending entries he might have received the amended schedule, and this is a kind of pressure on the committee by which the admirers of any comparatively unacknowledged variety of fowl may make themselves heard.

## THE LAWS OF NATURE

IN RELATION TO POULTRY KEEPING FROM A COMMERCIAL POINT OF VIEW.

In my preface I stated that I should confine myself exclusively to giving publicity to such facts as I had proved by actual experience. My knowledge of the world cautioned me not to introduce anything which might savour of theory, particularly to a class of readers who undoubtedly by their education are conversant with the laws of nature, on which facts are based. I was, therefore, but little prepared to have so many questions to answer, which more or less compel me to do that which I endeavoured to avoid in fear of being considered pedantic. Though I feel flattered by the great interest my treatise has created, and though an explanation of the laws of nature will prove interesting to many, yet I trust that my correspondents will not consider it a want of deference on my part if I abridge as much as possible my explanations, but still with a due regard to giving a satisfactory reply to all inquirers.

### EGG PRESERVING.

1. Question: Does it make any difference to preserve eggs a

few days old?—The egg comes from the hen at blood-heat, the liquid then fills every part of the shell, gradually the egg cools, and the air contained in the egg is condensed, thus leaving a vacuum. Now as the shell is porous, and the pressure of the outer air much greater, it forces itself gradually through the pores of the shell until the equilibrium is re-established, thus forming the depression of the fluid part observable in old eggs at the round end; and as the contact of the air with the fluid part very soon alters the taste, and renders them unfit for hatching from, it becomes essential that the eggs should be preserved as early as convenient after being laid.

2. Why should eggs be preserved better in rarified air than by merely packing them in air-tight jars?—The variations in the temperature of the atmosphere from below freezing point to summer heat are important considerations in preserving eggs. The elasticity and expansive properties of air need not be explained here, as they will require a full explanation under the questions in reference to regulating heat. I will, therefore, only say, that if an air-tight jar were closed up during cold weather without the air within being first rarified it would, provided it remained air-tight, stand a good chance of bursting during the summer heat, which would expand the air in the jar, and the pressure on the eggs would be so great that a quantity of air would be forced on the fluid through the pores of the shell. Were it possible to preserve the eggs immediately on being laid at the temperature of blood-heat, and during the hottest summer days, the jars would not require rarifying; but as such conditions are almost impossible to command, as the eggs must unavoidably on cooling absorb a certain amount of air, and as the atmosphere might become still warmer than on the day of filling the jars, it becomes necessary to rarify the air in the jars even in summer, although not to such a degree as during cold weather. The air in the jar being thus rarified its fermentation through the shell will not only be prevented, but the excess of air in the egg will actually be withdrawn until the equilibrium is re-established.—G. K. GEYELIN, C.E., London.

(To be continued.)

## PRESERVING EGGS.

I CAN bear witness to the efficacy of the mode of preserving eggs, described by your correspondent "T. G." When they are carefully dried before being deposited in the crate, I have seen eggs preserved in this way perfectly sweet after the lapse of several years. Eggs, however, preserved in the ordinary way—that is, by rendering the shell impervious to the atmosphere, or by being placed in Mr. Geyelin's air-tight jar, are more useful in the kitchen, and those processes are more simple and expeditious than that of blowing each individual egg, which is necessary to the desiccation essential to the process described by "T. G."—K. S. M.

## HIVE TEMPERATURE.

THOSE apiarians, of whom there are large numbers who, at the present day, make the study of the honey bee a scientific pursuit, are aware of the advantages accruing from an equable temperature of the hive, and of the evils which may result from a fluctuating or rapidly varying temperature—not that it is desirable to obtain a warm temperature through the winter months, which might cause too great a consumption of stores, but that a hive should not be affected by those great fluctuations which all freely conducting materials must induce. We must all, however, agree that a cool hive is a great desideratum through the hot summer months, during which the crowded inmates may work instead of clustering idly at the front of their close and oppressive domicile. This object can be but imperfectly attained whilst we make use of a material so free in its conducting properties as wood, as variations of the external temperature must necessarily affect the interior. Straw has been generally considered in some measure free from this objection, but, during my thermometric observations I have found a very slight and unimportant difference between the internal temperature of wood and straw hives.

It may be remembered by some readers of THE JOURNAL

OF HORTICULTURE that in the spring of 1864 I gave a short account of experiments I was then engaged in respecting an altogether new material—namely, the compressed tan which is used in some localities as fuel. This substance is prepared by allowing large quantities of the spent tan to undergo decomposition, being then capable of acquiring the necessary form by considerable pressure in moulds, and upon subsequent drying forms a most efficient, cheap, and durable hive, well adapted to withstand those sudden fluctuations of temperature which so frequently occur. Three of these hives—tenanted last summer, one by an artificial swarm, one by a late and small second swarm, and one by a late cast from a first swarm—have passed well through the winter months; and two of them, at least, appear likely to be early and prosperous stocks this summer.

I should wish, however, now, more particularly to call attention to the unicomb tan hive upon which the observations given below were made; the results, it will be seen, as compared with the box being greatly in favour of the former. It may be necessary to state that neither the tan hive nor the box was tenanted with bees during the observations. I give the mean readings of three daily observations of the thermometers placed respectively in the tan hive and a box, the latter being well protected with an outer case; the external temperature being indicated by a thermometer placed in the shade and attached to the exterior of the observatory hive. In a future paper I may give a somewhat detailed description of this hive, but my present object is simply to call attention to the somewhat remarkable results as shown in this register, a portion of which only I give; for, although made for several weeks continuously, the readings have varied but slightly throughout. I may also mention that upon submitting the hives to a very high artificial temperature the tan hive remained but slightly affected, whilst the box soon obtained and continued to indicate a temperature almost, and occasionally quite equal to that of the room in which the observations were made.

Thermometric Register, showing the fluctuations of an observatory tan hive, a box hive, and the external temperature:

Date.	Observatory tan hive.	External Box hive.	External temp.	Date.	Observatory tan hive.	External Box hive.	External temp.
10	53.5	40.0	40.0	20	49.0	30.0	30.5
11	53.0	43.0	43.5	21	48.0	29.5	28.0
12	53.5	44.0	44.0	22	47.5	30.0	30.0

—GEORGE FOX, Kingsbridge.

### NEW BOOKS.

*The Apiary; or Bees, Bee-hives, and Bee Culture.* By ALFRED NEIGHBOUR. London: Kent & Co., and Geo. Neighbour and Sons.

MR. NEIGHBOUR says in his preface, "We are so frequently applied to for advice on matters connected with bees and bee-hives, that it seemed likely to prove a great advantage alike to our correspondents and ourselves, if we could point to a 'handy-book' of our own which should contain full and detailed replies sufficient to meet all ordinary inquiries." Keeping this object steadily in view the writer describes the various hives and apiarian apparatus manufactured by his firm, pointing out the various advantages claimed for them, and giving ample directions for their use. When we add that the author expresses his acknowledgments to Mr. Woodbury, Mr. Taylor, the illustrious Huber, and Mr. Langstroth, it may readily be imagined that the information derived from such sources must in the main be correct, and that Mr. Neighbour, in addition to the strictly business portion of his work, has been enabled to impart to his readers a very considerable amount of sound instruction on most points of apiarian management.

### RANCID BUTTER.

One of your correspondents inquires respecting the rancidity in his butter. It appears by his statement that

the dairy is generally managed with perfect order and cleanliness. That may be the case, but perhaps there may be in or around the pasture, where the cows are in the day-time, ash, oak, or elm trees. I can speak with confidence that if such is the case "COCHIN" will find it a hard matter to obtain good butter.

Again, perhaps, he gives them turnips when they come home at night. Now turnips will not affect the butter of some cows as much as it will that of others, but I attribute the rancidity to the leaves, because "COCHIN" says that the butter is always rancid in autumn.

I would recommend "COCHIN" to place in the manger a lump of rock-salt.—T. L.

### OUR LETTER BOX.

**HEN EATING NEARLY-HATCHED CHICKENS (C. E. B.).**—It is unquestionable that fowls are fond of flesh for their food, even when in perfect health, but there are peculiar conditions of body in which they have a craving for what we should consider most unnatural food. It must be considered so when a hen anxiously waits to eat the egg the moment she has laid it. In the first instance it was a desire for the shell only that made her eat. She found she did not possess the proper material, and could not find it; but when she had tasted the egg she liked it, and from that day she was an egg-eater. We have no doubt the cannibal hen you complain of, which broke the eggs and ate the chickens within, sought only the shell, but she saw the chicken and ate it; she liked it, and she ate another. She will eat all she can get; kill her at once. Watch your fowls if an unhappy frog makes its appearance on the grass of their run. Young pullets that have never eaten anything but grain and vegetables will start back at the first jump he takes. They then follow and watch him; then they peck him; and all fly upon him; three or four peck at him at the same time. You will see the fortunate possessor chased by the whole brood all over the meadow, but they will never leave him, and at last he is eaten. The next they see has a much shorter shrift. The same if one of a walk gets an injury that bleeds, all the others begin to peck and eat. Every bird acquires the habit, and for that reason also we advise you to kill the hen. If you leave her at liberty she will cast you during the season her own value twice over.

**COCHIN-CHINA COCK DYING (Niobe).**—We should think the Cochin cock that was almost a skeleton, though well fed, died of atrophy. It is certain that if there were any assurance office for the lives of fowls, cocks would have to pay double premiums as compared with hens. We believe that many Cochin-China cocks die in the act of crowing; we have been eye-witnesses of it. We have seen them prolong their crow till they had brought their heads down between their legs, and the end of their crow was the end of their lives. All Cochins are liable to apoplexy; they are large eaters, and take little exercise. Your feeding is good, the house is all that is desirable, and they do not suffer from cold. Your Pigeons are some of the German Tumblers.

**GAME FOWLS, BLACK AND BROWN-BREADED (Partlet and Chanticleer).**—You may safely breed between the Black-breasted hens and Brown-breasted cock, and the probability is you will breed some good birds of both. The breeders of pure birds of both strains commonly intermix to attain certain desiderata. Your description is that of pure Brown Red pullets, and although some of the cocks may follow the father, you will most likely find some of them Brown Reds. Your food is, if anything, too stimulating, and under ordinary circumstances you may discontinue the greaves. The pullets lay because they are pullets; they will not lay in the winter when they are hens. The latter will soon lay. Your last is a vexed question. If your hens were taken from the old cock at the end of December we think you may safely now set their eggs, believing you will breed from the fresh one.

**EGGS OF AYLESBURY DUCKS (A Constant Reader).**—You must not conclude unfavourably from the colour of the eggs. They vary, even when laid by the same Duck, from white to pale bluish-green.

**MR. DOUGLAS.**—This member of the Poultry Club writes as follows:—"The pen 'A TIMID EXHIBITOR' alludes to as bought and sold at Manchester was claimed when above one hundred were in the Show. It was claimed in my name, not by me; neither was it sold by me."

**DIRECTION (T. Collison).**—It is Mr. F. W. Zarhorst, Belleville, Donnybrook, Dublin.

**MINGLED FOWLS (Helensburgh).**—No possible cross in the Spanish can be the consequence of a Spanish cock being with Hamburgh, Dorking, and Spanish hens. How long the taint may continue in the Hamburgh and Dorking hens is a question yet undecided.

**SALT FOR CHICKENS, &c.**—Mr. Geyelin cannot give the required information about M. de Sora's chicken food. The other questions will be answered in the regular course, with many others on the same subject.

**COW EATING CEDAR LEAVES (J. E. B.).**—The cedar leaves would not injure her. The steep bank and its slippery surface, down which she had rolled, prevented her recovering her feet.

**DOE RABBITS NEGLECTING THEIR YOUNG (J. N.).**—Different causes have been assigned for this unnatural proceeding. We believe that it usually arises from a deficient secretion of milk in the doe, and this deficiency is often caused by the food being too fattening. We shall be obliged by information on this subject.

**SHELL PARROTS OR EURORIGERAS BUILDING (J. S.).**—The cage should be placed in some retired situation, and not moved. At the end of the cage place a rough box about 5 inches square, containing the nest already shaped, composed of dry moss, grass, and wool, similar to what Canaries build with. Let there be some of the same materials loose in the cage. For further particulars see our Journal, New Series, No. 53, "Australian Parroquets."

**BLENHEIM SPANIEL SHEDDING ITS COAT.**—"A. N." has a spaniel of this breed continually shedding his coat, and wishes to know the cause and a remedy.

**GROWING INDIAN CORN (A. Z.).**—It cannot be grown in this country except in the southern counties, and in unusually long, warm summers.

WEEKLY CALENDAR.

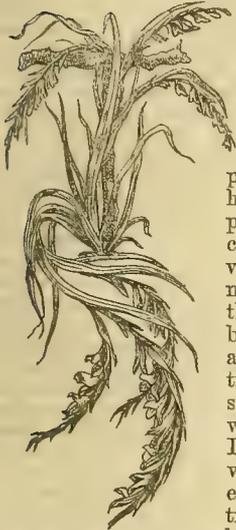

Day of M'nth	Day of Week.	MARCH 7-13, 1865.	Average Temperature near London.			Rain in last 28 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 50.0°, and its night temperature 32.2°. The greatest heat was 67° on the 10th, 1826; 12th, 1841; and 15th, 1828; and the lowest cold, 7°, on the 10th, 1847. The greatest fall of rain was 0.69 inch.

THE MODERN PEACH-PRUNER.

No. 5.

ASPECTS AND SHELTERS.

THE proper aspect for the Peach tree in England should be as nearly due south as can be secured. South-east ranks next, and after this south-west. Much, however, depends on the locality of the garden and the position of the nearest shelter from high and cold currents of air. The prevailing winds must be carefully considered as to their effects on vegetation, and the Peach wall removed as much as possible from their full force. In France, M. Dubreuil recommended the south-east as the very best aspect. At Montreuil, where the sun's rays are scorching in summer, an east or west aspect is generally preferred. In mid-France they place the late varieties facing the south. The early kinds and the bulk of the trees are assigned to the east walls; but none are placed on west walls

if it can be avoided. At Montreuil so powerful is even the early sun that trees flourish which have no sun after 10 A.M. In such aspects, however, the trees make very long shoots, and give extra trouble to the pruner.

The proper height for a good Peach wall must be regulated in some measure by the situation. Where the ground is level and the aspect south the wall may be the highest. Very splendid fruit can be grown even on walls 6 feet high; indeed, many are greatly in favour of low walls as promoting free circulation of air in low and confined situations. The Montreuil walls are only 8 or 9 feet high; but then the form of training there admits of no riders, and favours considerable lateral extension of the branches. If low walls are adopted—that is, about the height of those at Montreuil—about 20 feet horizontally will be requisite for the trees to develop themselves laterally. If, on the contrary, the garden wall be 12 feet high, the trees may be planted at 15 feet intervals from stem to stem, with riders placed midway between them to cover the upper parts of the wall, which the dwarf-trained trees below could not ascend to. In favourable soil and climates the Peach tree, when doing well, will, however, greatly exceed these limits, but there is nothing gained by these immense trees. It must be borne in mind that the modern methods of training the Peach do not favour such extension; they rather favour the practice of having more trees in the same space, by which plan many advantages are gained, as will be seen presently.

Of the utility of copings there is little doubt. These should be fixed, and projecting not more than 3 or 4 inches, as more than this would shade the upper

branches by June, and intercept the dews and warm summer showers. Besides these permanent copings iron brackets should be fixed into the walls close under the copings. These brackets should project outwards about 12 inches. They should be of the shape of a triangle, one side secured against the wall, and on the upper side boards of inch-deal should be laid and screwed to the brackets. When the fruit has set, these boards should be removed and laid by till in many localities where the rainfall is great the heavy rains of September necessitate their being replaced. In southern districts this may not be required.

But the Peach requires other defences against the bad weather in the shape of stout tiffany screens or protectors reaching from the brackets to within 2 feet of the ground. Lower is not needed for the safety of the blossoms. These protectors should be used from February till the fruit has fairly set, and they should be left off gradually. Their object being to protect the young leaves, and especially to favour the setting of the fruit, they should be drawn up during the day, and let down only at night, or during storms of wind and rain, or fogs. Great care is needed not to stifle the growth of the tree. On the utility and daily management of tiffany protectors I quote from a letter from the Rev. W. F. Radclyffe. To show how situation affects temperature he says, "Being in a valley close to the water the frosts are severe. After black frosts cease, for eight or ten weeks hoar frosts succeed. It would be hopeless to grow Peaches without efficient protection. Fir boughs and netting would here be moonshine. I find the leaves even more tender than the blossoms. In severe winters like this I keep on the protectors, unless the weather is mild, by night and sometimes by day. Snow or sleet should never get into the trees. The protectors are put on as soon as the fruit-buds swell. They are let down at 4 P.M. and raised in fine weather at 10 A.M. If the weather is bad they remain on even for several days. They must be left off gradually, as cold draughts are injurious."

It remains only to mention that I have seen instances where much injury was done to the trees by these protectors being placed too near to them, the wind by impinging directly on the surface of the protectors causing them to beat sharply against the leaves and blossoms.

It seems useless to expect a crop of Peaches, even in favoured localities, without some such protection as the above. Nor is the expense great, these protectors serving for several seasons, and the trouble is amply repaid. During the hard frosts of winter the Peach tree may suffer; but the danger is not in reality great in ordinary seasons provided the wood of the tree is ripe. The difference this makes in the welfare of the tree is very great, nor is it surprising when we remember that the Peach is a native of Persia. Though the winter frosts of that country are exceedingly severe, yet the Peach tree survives them simply because the fierce sun of the preceding summer has most thoroughly ripened the young wood; it is rather the excess of autumn rainfall in England, after a cloudy summer, which endangers the vitality of

the tree. If to this be added injudicious pruning and cold undrained borders, what possible chance of success can be expected?

Let us, then, be very careful to secure such an aspect as shall best ripen the wood; then shelter from cold currents of wind mingled with rain must be obtained. Generally speaking such shelter should be perpendicular, facing the wall. Air is elastic and readily turned aside. Openings, however small, must increase the violence of the blast. Plunging winds without outlet, as in the case of small gardens enclosed by high walls, are extremely unfavourable. Imagine such a rush of air for hours together, and directed against unsheltered trees, and this during a period of low temperature, and then you will feel no surprise at their being unproductive and diseased.

Every advantage, then, must be taken of neighbouring shelter in laying out a garden. On the western coasts the general exposure of the whole garden should be sheltered from the south-west quarter. In the Channel Islands, exposed as they are to the force of the Atlantic gales, this is carefully studied. Each year brings disasters to our gardens, and we do not so much dread winds from an eastern quarter as from a western. In the eastern counties of England, however, all testimony goes to prove how fearfully destructive to the tender leaves and shoots of the Peach are the cold evaporating effects of a continuous east wind. Above all, let the amateur direct his attention to securing this shelter without losing unnecessarily one precious ray of sunshine in our cloudy regions: therefore the protection must be somewhat distant from the trees and yet not too far. On very long walls temporary screens placed across the borders so as to deflect the scud of the wind are advantageous, but buttresses to the walls throw a dangerous shade, and are not to be recommended.

The material of which the wall is constructed is not very important. Brick seems on the whole the best material, and wire trellisses are, no doubt, by far the best to use for training purposes and for obtaining beautiful forms; still the old shreds of cloth have many advantages, as have also studs fixed in the wall for training to them with soft-wire. The great object is to secure the radiated heat of the wall. It is astonishing what a difference an inch makes in this way. Some have even recommended obtaining a succession of crops by varying the space between the branches and the wall, but modern practice relies more on the numerous varieties of fruit now known.

The "Modern Peach-pruner" has no faith in the practical utility of heated walls. What are glazed coverings for Peach walls but narrow and stifling contrivances to effect what wide and commodious orchard-houses do so much better? When once we desert the time-honoured open wall, now so elaborately furnished with Peach appliances, why should we adopt half-measures and middle courses? not to speak of the great advantage of combining the two methods so as to secure the best of each. I mean that in a combination of a good Peach wall, with a properly-managed orchard-house, the amateur will find everything he can reasonably desire. This, at least, is within the reach of many, whilst the more expensive heated Peach-house can still be added by such as wish an earlier produce.—T. C. BRÉHAUT, *Richmond House, Guernsey.*

#### SOIL SUITABLE FOR THE RHODODENDRON.

SOME years ago the Royal Agricultural Society offered a prize for the best essay on the causes of fertility in soils, but the different writers were far from unanimous in the conclusions to which they came. One fact, however, was adduced, or rather an old idea was confirmed, that certain classes of plants require food of a widely different character from others—hence the different plants found wild in different localities—and that if the soil is of an extreme character the presence or absence of these plants affords a tolerably good indication of what cultivated plants will thrive on the spot. On the other hand, there are intermediate soils which are much more difficult to understand than those of an extreme character, and now and then failures take place with them of a kind neither looked for nor easily explained; but until chemistry assists us with some easy mode of testing soils we must be content with occasionally stumbling in

the dark; and as one of the errors alluded to occurred here with plants under my own management, I deem it quite as much a matter of propriety to make it known as if unexpected success had followed the operation. The case was this.

About three years ago it was determined to take into the dressed grounds a piece of pasture land that was well sheltered on all windy sides by high and thriving trees. The soil was what would be considered by a farmer all that he could wish for, being deep, mellow, and sufficiently dry to require no artificial draining, yet not so hot as to suffer too much from long-continued drought in summer. The soil at 2½ feet down looked almost as good as at the top, and the stony subsoil below that was so favourable to the roots of trees, that I expect some have made their way for 10 or 12 feet downwards; for in sinking a well some distance from the place, but in soil of a similar description, roots of trees were found 22 feet below the surface. This I merely mention to prove the healthy character of the subsoil, or, at least, to show that it favoured the growth of certain trees, while the surface produced us the heaviest crops of hay we had anywhere. I may also add, that most forest trees thrive well, Elms particularly so; while not very many yards off were some old Apple trees with boles approaching the size of moderately large timber trees, and although these patriarchs had ceased to be depended on for producing a crop, now and then they did furnish us with a few bushels of kinds that seemed to have passed out of cultivation, but which are, nevertheless, not without merit. I might also add, that most shrubs and Conifers seemed to do well in this soil, *Pinus Douglasii* excepted, and that probably from some cause that might be accounted for in another way. It was thought advisable to try *Rhododendrons* on this newly-enclosed plot, and as these have not prospered as well as could be wished, some description of the mode adopted may, perhaps, prevent others falling into a like error. At all events it will show, that a soil so good in many respects was, nevertheless, deficient in some of the qualities required by the *Rhododendron*; while the common Laurel, *Laurustinus*, and several species of *Cupressus*, *Pinus*, and *Wellingtonia* flourished, the *Rhododendrons* dragged on a wretched existence, some, though not many, dying, and the most of them merely growing 2 or 3 inches, and having naked stems.

Now, though I attribute the non-success of the *Rhododendrons* in a great measure to the natural soil of the place, I am not certain that it is entirely due to that cause, and have sometimes had doubts whether the mode I took to promote their well-doing might not have had a contrary tendency. I may state, that we have no good black heath mould in this neighbourhood, and have to bring it ten or a dozen miles, consequently, it cannot be had for out-door purposes so freely as desirable. A cartload or two of boggy peat was sent me from a shorter distance, this I soon found out would not do for potted plants, but anxious to turn it to account, I mixed it with other ingredients—as leaf mould, sand, and the refuse of a timber-yard, making the whole into a large heap. The beds for *Rhododendrons* having been prepared by trenching, about half a barrowload of this mixture was used around the ball of each plant. The weather at the time was favourable to planting, and although the spring was somewhat dry, I expected better results than what followed, or, at least, that the plants would have done better the following year, but such has not been the case. I have, therefore, come to the conclusion, that there is something radically wrong, and although I may possibly be wrong in my surmise as to the cause of the non-success of the *Rhododendron*, I will, nevertheless, state what I conceive it to be, and will afterwards record an instance of failure in the cultivation of this plant in a widely different case.

I have said that a portion of the mixture applied immediately around the ball of the newly-planted shrubs was a black boggy peat, which evidently contained mineral substances pernicious to the *Rhododendron*, at least it was so to Heaths and Azaleas, and excepting the coarse marsh plants which it supported in its natural bog, I should think it was ill-adapted for anything else; but I expected that by mixing the peat with five or six times its bulk of other substances, its injurious qualities might have been modified, or, perhaps, neutralised. I have also stated that some refuse

from a timber-yard, consisting of rotten bark and chips, with, probably, some very old sawdust, formed a portion of the mixture. This material, at the time, I took to be inert rather than injurious; and from the fact of weeds growing luxuriantly in it, I felt assured that it could do no harm, and with the large quantity of leaf mould, sand, and boggy peat used would, probably, prove beneficial. Perhaps, however, the presence of bark from resinous woods—as Scotch Firs and Larch, might have a deleterious effect, and, I believe, such bark is generally objected to; but as Scotch Fir in particular seems to grow wild on dry peaty soils favourable to the Rhododendron, the inference I drew was, that the bark ought not to be hurtful. Certain, however, it was, that the better class of Rhododendrons made no progress in it, or grew very slowly, while the common kinds, as *R. ponticum*, did very well; also, other shrubs which received a share of it in another place. Although the mixture was unsuitable to the hybrids of this interesting family, it evidently contained nothing injurious to anything else.

In contrast with the above case, but also affording another instance of unsuccessful treatment of this somewhat capricious tribe of plants, a friend of mine, some short distance from here, having a small piece of marshy boggy peat which supported some very good Silver Firs on its elevated parts, and had its lower portions studded with Alder and Willow, had the latter removed and the whole well drained. After being trenched, part was planted with Rhododendrons in the full expectation that they would do well; whereas, they have absolutely done worse than mine. The kinds in this instance were also hybrids worked in the usual way, and good healthy plants when they were planted. I believe the numbers that have actually died have been more than with me, and the remainder show little signs of accommodating themselves to their present home. Now, this case differs widely from mine, and at the same time is equally unfortunate, or more so; as with me the common varieties thrive tolerably, while with him all are bad. I ought, however, to remark, that the boggy peat was so charged with feruginous matter, that the water drained from it encrusted its bed a bright red colour; but I have seen this before at a place where Rhododendrons succeeded admirably, but the issue shows that our acquaintance with such matters is far from perfect yet.

Now, as some soils contain within themselves all that can be desired to make the Rhododendron flourish, it behoves us to look round for some simple test as to what that requirement consists of. In my own case, I confess being unable to give the chemical constituents, but a study of the classes of plants found growing wild there would greatly assist in doing this. Certainly this is better than any other mode I am acquainted with, and less likely to lead to disappointment than being guided by appearances only; for soils as much unlike each other as possible are found to be equally favourable to the growth of Rhododendrons. In very many places these sow and reproduce themselves by thousands, and the more rough and overrun with weeds and rubbish the better the young seedlings seem to thrive. The dry black peat of upland moors is not by any means the only soil they like, as I have seen them do well in apparently a yellow sand, while a sort of yellow sandy loam is very often more favourable to them than the black peat, and nothing can exceed the luxuriance of some of the common kinds which we have growing on ground which is at least two-thirds stones. Sometimes they grow not amiss in a damp clay, although cases of this kind are more rare than the others; but to the amateur who may not have had experience in such matters, I would say, that in those districts where the Foxglove predominates among other wild plants, there he may plant the Rhododendron. The wild Heath, no doubt, is an equally good guide, but it is more sparingly distributed. I do not mean to imply that a solitary plant or two of Foxglove will be sufficient to insure success to the Rhododendron, as accident may have placed them there, but where successive crops of this beautiful native plant exist, struggling with and overcoming the other herbage of the place, there the Rhododendron may be planted with a fair prospect of success. The wild Fern is a less certain guide, unless it predominates almost exclusively, for it is often found on soils not suited to the Rhododendron. It is, however, a frequent occupant of the same plot. Other and less conspicuous plants

also abound in such places, while some of our wild Orchises grow in soils exactly the reverse of that required by this plant, and to which it would be folly to remove it. When chalk and lime predominate, it is hopeless to expect success with the better class of hybrids, and the common ones will only be able to live; to luxuriate is out of the question. The subject is well worthy of attention, and more information may be given by those residing in neighbourhoods where the Rhododendron flourishes better than any other evergreen, which it certainly does in some of the midland and western counties.—J. ROBSON.

### CONSTRUCTION OF PITS.

I PURPOSE making two frames, one cold, to use for wintering plants, the other for propagating. They will be 6 feet from back to front. Oblige by saying how much higher the back of each should be than the front. The propagating one, I understand, must have the most slope. I purpose making the latter—say 3 feet below the ground-level, and to have a trench 2 or 3 feet wide round it, to line with spent bark. The wall below the ground-level I purpose having half-brick-thick, above it one brick. I conclude the heat would pass more freely through the openings in the thinner than the thicker wall; and if I should be under the necessity of using it also as a cold frame, the nine-inch work above ground will keep out more frost. By keeping the linings in, of course the frost could not pass that way.—TYRO.

[What are generally termed frames are boxes made of stout wood, with glass sashes to suit. These are generally made with one, two, or three lights. Your proposed erections are pits, being built of brick, and therefore stationary, whilst frames are easily moved from place to place. If your cold pit and propagating pit are to be in the same range, there is no necessity for their being of different levels, or having their glass in different slopes. For pits 6 feet wide, you will have a nice slope if the back wall is from 20 to 26 inches higher than the front one. You propose making your cold pit of nine-inch brickwork, and that will do very well. If you have a good bricklayer, who would tie a nine-inch hollow wall properly, it would be warmer in winter, and cooler in summer, than a solid one. If you mean to set your plants on the floor of the pit, say rough ashes, &c., then it would be as well if the floor were a few inches above the outside ground-level, some small openings being left in the wall, to allow moisture to escape. If you make it deeper, that will be no loss, if you elevate boards on which to set somewhat dwarf plants, as, the greater the amount of air enclosed, the longer will that air be in heating or cooling.

Now, as to the propagating pit. You purpose sinking it 3 feet beneath the ground-level, and surrounding it with a trench 3 feet deep and 2½ wide, which we think all right; the bed inside to be built of tanner's bark, and the lining also to be filled with the same. Now, we must here observe that, in using tanner's bark for a bed, when the heat declines, the adding a barrowload or two of hot tan to a light inside, mixed with the old, will do more to increase the heat than three times the quantity from the lining. As to the lining itself, to secure its efficiency and neatness, it should be covered with wooden flaps on the ground-level, the flaps sloping, say 1½ inch, from the wall to the ground, so that you can walk by the side of the warm pit as comfortably as by the side of the cold one; and then, if the lining sinks, the heat will still be directed against the wall or bed beneath the ground-level, being sent back by the boards instead of going into the atmosphere.

With your proposed plan of having a single brick-on-bed, we presume below the ground-level, so as to obtain heat from the lining, and a nine-inch wall above, we have no fault to find, though you do not describe how you mean to join the nine to the 4½-inch work. It is rather contrary to the common mode of building, in which the lowest stories ought to have the thickest walls. We think it would be an improvement to have nine-inch piers every 4 feet, and a flattish arch between every two piers, the crown of the arch being at least 6 inches below the ground-level. If you were quite sure that the bed inside, whether of dung or tan, or both, would always be 1 foot above the top of the arch, then you

would need no wall beneath, and the linings would at once act on the bed. There would be little danger from tan, but there would be from rank dung in the lining, if the bed inside were not fully 1 foot above the top of the opening. If this deep pit, when cleared out, should be used for keeping tall plants in during the winter, it would be better to fill in the openings of the arches with brick-on-bed, and better still if well done with brick-on-edge, and cement joints. Brick-on-bed would be more secure if tried with a thump from the fork. In finishing such a wall a bent pipe should be inserted beneath each arch, to admit moist heated air into the atmosphere of the pit when deemed desirable. We need not say how dry heat could also be obtained for the atmosphere of the pit, by allowing this wall to project into the pit a couple of inches, and on this projection fixing slates or sheet iron,  $1\frac{1}{2}$  inch from the nine-inch wall, but making all steam-tight. A very simple plan for securing top heat from the linings would be to have two or three holes, say 2 or more inches square, in each arch, and then build the nine-inch wall above it hollow. The heat that rose from the lining would thus rise through the wall, as well as heat the bed against which the lining was placed. With plenty of heating material anything might be done in such a pit, and more especially if from November to May a little straw were neatly tied against the outside walls above ground. This is much better than using litter, and it does not require so severe a frost, if continuous, to go through a solid nine-inch wall. Many have carefully protected the glass and let the enemy in by the wall.]

#### HEATING AND GLAZING A SMALL CONSERVATORY.

WHAT is the best way of heating a conservatory about 18 feet by 12, where economy of construction and working is a consideration? I want, if possible, to avoid the necessity of having a fireplace, chimney, &c., on account of appearance. Are any of the systems which do not require this, thoroughly effective? Mussett's Patent, for instance, which is a moveable coil of pipes, heated by two lamps? I have heard that there is something in this and similar systems, which have the fire inside the building, injurious to plants, if not unpleasant to the smell?

Is ribbed or fluted glass suitable for the roof of a conservatory, or does it obscure the sunlight too much?—N. P.

[Relative to heating, we can add very little to what has been advanced in previous Numbers. We strongly object to heating by oil lamps, or gas, whether as a stove or with hot water, and to stoves with prepared fuel, unless there is a pipe or other arrangement for taking the products of combustion out of the house. Many small conservatories close to the mansion are heated from a kitchen boiler on a lower flat, but then you will be a little dependant on the cook. The most economical of all for such a small place, would be a brick stove with a pipe through the wall. The least cumbersome would be a small iron stove with a pipe through the glass roof, as the whole could be taken out from the middle of March to the end of October. The brick stove might be fed from the outside, the iron one from the inside. A little care in damping when cleaning out, and using a little dry wood for lighting, a few nodules of coal then, and coke and cinders afterwards, would involve but little trouble, and cost much less than oil or gas. We have no doubt that Mussett's Patent and other stoves and boilers do well with common care and attention, heated either by candle, oil, or gas, the last two the best. If, as said above, there is a pipe to take off the smoke, however little, that pipe will also give out heat; but, as stated the other week, the minutiae must be attended to. We prefer ribbed, fluted, or rough glass, if good, for the roof of a conservatory. Plenty of light will pass through it, and you will need no shading. The front lights of clear glass, however, look best.]

HOW TO KEEP PEARS.—Permit me to correct one or two slight misprints, owing doubtless to my crabbed handwriting. In the second paragraph "other pots" should be "these pots." At the end of the third paragraph "these very late Pears" should be "the very late Pears."—T. R.

#### GROWING MUSHROOMS AND BLANCHED VEGETABLES IN A CELLAR.

COULD Rhubarb, Sea-kale, and Mushrooms be grown in any of the cellars hereafter described without fear of engendering damp and unwholesome smells?

1. An underground cellar, paved with brick, about 7 feet by 7 feet, 6 feet high, with a small window to the open air near the top, and situated under a dwelling-house.

2. A cellar level with the ground floor, 6 feet by 6 feet, 8 feet high, gravel bottom, no communication with the outer air, a living-room over it.

3. A cellar level with the ground floor, not communicating with the house, gravel floor, door to the open air, no window, a living-room over it, 12 feet by 10, and 8 feet high.

If Mushrooms could be grown in any of the above without fear, what would be the best time to commence a bed?—BANKS OF THE THAMES.

[For the first there would be no danger whatever. If the room is ceiled, all damp affecting it would be neutralised by brushing the ceiling over with boiled oil; but with a window we do not think there would be any damp to injure anything. The advantage of an underground cellar is its equable temperature. This would answer well for Mushrooms in summer, if the window were blinded to keep out the heat. A bed may be made at any time.

2. This can hardly be called a cellar, and it would be of no more use than any other close room or shed. It would not do for Mushrooms in summer unless kept cool, and Rhubarb, Sea-kale, and Mushrooms in winter could only be grown by artificial heat. If there is a door to take the materials in without going through the house it would do very well. With no ventilation the ceiling should be secured with oilcloth, or oil brushed over it.

3. The advantage of this is having the door to the open air. This would do for Mushroom-beds all winter by covering the beds when made, according to the weather. Rhubarb and Sea-kale would be produced all the winter by placing the roots in a mild hotbed. The ceiling should be protected, or a ventilator placed above or on the top of the doorway. Such a place, kept at about 55° or 60° will give good cuttings all the winter. There is no necessity for the place as a whole being kept to that temperature, but the roots may be covered so as to secure that temperature about them, taking off the covering when not wanted.]

#### WINTER-FLOWERING PLANTS.

THE following are a few more of the useful winter-flowering plants not in Mr. Jones's list, and I hope they will aid in giving a still more lively appearance to his already enlivening collection. The chief of these have been in flower since November, or will do so before April.

In the stove:—*Franciscea eximia*, *confertiflora*; *Æschynanthuses*; *Echmea fulgens*; *Torenia pulcherrima* and *asiatica*; the beautiful *Gesnera cinnabarina*, *splendens*, and *zebrina splendens*; *Jasminum gracile*; *Rogiera cordata*; *Begonia Digswelliana*, one of the freest of winter-flowering plants. We have at the present time plants in 24-sized pots, 14 inches high by 18 inches in diameter, covered with bloom; besides standard plants in 32-pots, 14 inches high in the stem, and having compact heads, 7 or 8 inches in diameter loaded with pendant rosy purplish flowers. Besides these there are the elegant little *Sonerilas*, with their feathery-looking rosy pink blossoms. *Gardenias Fortuni*, *florida*, and *citriodora* are more or less commencing to flower. In stove bulbs there are the bright-coloured *Amaryllis aulica fulgens*, *Johnsoni præcox*, *crocata*, &c., *Imatophyllum miniatum*, *Eucharis amazonica*, *Pancratium*, and others.

In the greenhouse are:—*Daphne odorata alba*, the sweeter one of the two; forced Oranges in flower; *Hovea Celsi*; *Habrothamnus elegans*, in flower all the winter; *Acacia longiflora magnifica*; *Coronilla glauca*; varieties of *Cytisus*, with forced Lilacs, *Weigelas*, *Deutzias*, *Sweet Briar*, *Mignonette*, *Nemophila*, &c. In greenhouse bulbs the most prominent and useful are the *Cyclamens* in their several kinds; *Coum*, *persicum rubrum*, *persicum album*, *Atkinsi*, and others are the most showy; though I regret to say that in consequence of the great demand for them the

trade have been driven to procure home-grown seedlings, very many of which are very far inferior to the original ones. In addition to the above there are *Lachenalia quadricolor*, *pustulata*, and others; *Oxalis fulgida*, and *sanguinea*; *Triteleia uniflora* (forced); the prim little *Oxalis tricolor*; *Phædranassa chloracra*; *Ixia scillaris* (variegated); *Hymenocallis Skinneriana*; *Scilla brevifolia*, *bifolia*, &c.—W. E.

### MR. ABBEY'S PLAN OF PLACING STRAWBERRY SHELVES.

At a moment when Strawberry forcing is in progress, and very many gardeners and amateurs are obliged to resort to various contrivances to secure additional space and suitable positions in their forcing-houses for the Strawberry plants they wish to force, the plan described and illustrated in the article on "Strawberry Forcing" in a recent Number of your Journal by Mr. G. Abbey may seem to some of those who are inconvenienced by having more plants to force than space to give them, a very opportune and useful suggestion, and as far as regards the extension of space for Strawberry pots in a house it may be so; but in respect to the suitability of the plan for successful Strawberry forcing I venture to express a doubt. In Strawberry forcing it is undoubtedly an advantage to place the plants on shelves near the glass, and Mr. Abbey's plan secures to the plants one of the conditions it is desirable they should enjoy; but with that proximity to the glass there should be a provision for the admission of air, not in strong sweeping currents when the sun shines, but slowly and steadily; in short, there should be an equal yet restricted play of air about the plants night and day. It is very necessary to prevent undue heat and dryness operating upon the plants, as excess in these particulars tends to interfere with the setting and swelling of the fruit. Placed as the shelves are seen in Mr. Abbey's design, it would be difficult in ordinary houses to preserve the plants from the scorching effects of the sun in the bright drying weather of March, and the exposure of the Strawberry-pots to the sun's rays and the currents of air necessary to keep down the temperature of the house, would dry up the soil and injure the roots, which should always be kept cool and moist. Having tried, some years ago, the plan now suggested by Mr. Abbey of hanging Strawberry shelves, and found the objections to it which I have stated, I am induced to speak with greater confidence; and I was led to devise the little Strawberry forcing-houses which bear my name, in consequence of the difficulty I found in securing suitable places for Strawberries in ordinary forcing-houses. I was led to the idea of my plan by finding that Strawberries always succeeded on shelves placed in the front of lean-to houses close to where the roof-lights rested on the front-supporting plate, and where a little air constantly entered; at the same time the pot was shaded from the sun by the thickness of the plate.

In other respects I am glad to bear testimony to the propriety of the recommendations in regard to Strawberry forcing in Mr. Abbey's very able article.—WILLIAM INGRAM, *Belvoir*.

### THE EXHIBITORS' LETTER TO THE COUNCIL OF THE ROYAL HORTICULTURAL SOCIETY.

YOUR correspondent "F.R.H.S.," page 126, writing in defence of the Royal Horticultural Society's programme for the present year, alludes to the sameness of the exhibitions from the repeated success of the same subjects; and, like the majority of those who write on the matter, he falls into the mistake of treating these exhibitions as mere spectacles for the horticultural sightseer. Now, I say without the least hesitation, if that were the chief and highest object in view, the exhibitions would be comparatively useless. To persons who are in the habit of seeing all the London or leading provincial shows, I admit there is not that novelty which many people are always craving for; but there is another very important matter which novelty-hunters lose sight of—namely, that at any one of those exhibitions there are hundreds of ladies and gentlemen, and also gardeners, who for the first time see a first-class horticultural show, and whose tastes for horticulture receive a stimulus on the

one hand, and on the other an incentive to and opportunity for observation, such as nothing else has the power of affording.

By all means encourage fresh subjects as far as practicable without lowering the character of the exhibitions; but it is well known to persons experienced in plant growing that comparatively few of the plants introduced to this country can be made subservient to the skill of the gardener so as to become fit for exhibition purposes. Although the same varieties, and in some cases the same plants, are generally successful, still I maintain it is better even so than to supplant them by subjects that are less calculated to exemplify what it is possible to accomplish by first-class culture.

"F.R.H.S." asks, What have those "magnificent specimens" to do with horticulture? More, I maintain, than any person can calculate, by the example they place before those connected with horticulture in all its bearings. Critics to be consistent ought to turn round upon the fruit-growers, something in this fashion—"We are tired of seeing your magnificent Pines, splendid Grapes, Peaches, Nectarines, &c., and request you to ransack the globe to find fresh fruits to operate upon; if they are fine-looking and palatable so much the better, but something fresh we must have."

If the London societies wish for fresh exhibitors, with probably a few different varieties of plants, then they ought to make a few classes for distant exhibitors—say those who reside 150 or 200 miles away. Not that provincial growers are afraid to compete with those near the metropolis, but simply for this reason—plants which have travelled so far cannot possibly look so fresh as those grown near to the place of exhibition, not so much in consequence of the distance as the time that stove plants must necessarily be out of their proper temperature before they can be placed on the exhibition stage.—T. BAINES, *The Gardens, Summerfield, Bowdon, Cheshire*.

### DEVONIENSIS ROSE.

I QUITE agree with Mr. S. J. Pavitt, of Bath, in thinking there is but one variety of this Rose, and I have much pleasure in giving my testimony as to the extraordinary vigour and hardiness of the plants sent out by him. There are at present growing in the garden of Henry Abbot, Esq., of the Priory, Abbots Leigh, near this place, three *Devoniensis* plants budded on the Briar, which I purchased for him of Mr. Pavitt in the year 1862, and which for size and vigour surpass any Rose plants I have ever seen. They are all three planted side by side against a south wall, one of them covering a space of upwards of 40 feet wide, and having shoots of the last year's growth from 10 to 16 feet long, and measuring in circumference at the base the extraordinary size of 2½ inches.

All three plants were last summer covered with blooms far surpassing in size and beauty any Tea Rose I had ever before seen, and I may, perhaps, add that my experience as a Rose amateur and visitor of Rose exhibitions has been by no means limited. On the occasion of my visiting Mr. Pavitt's nursery to purchase these plants, he took me to see some *Devoniensis* Roses sold by him, and growing in the garden of a gentleman residing near; they were grown as pillar Roses, and for rampant growth and vigour could scarcely be equalled by Charles Lawson, which for a pillar Rose would, I suppose, be considered one of the best summer Roses ever sent out.—R. C., *Clifton*.

THE UNITED HORTICULTURAL SOCIETY.—A meeting has been held for the purpose of establishing a society under this title. Various rules were adopted but we have only space to spare for their preface:—"The objects of the Society shall be to promote the practice, study, and advancement of horticulture in all its various branches; means shall be especially taken for the examination of plants, flowers, and edible fruits, their nomenclature and synonymes, establishing their relative merits, investigating their physiology and diseases, their uses, properties, cultivation, and improvement; also to facilitate the formation of a fund for the benefit of gardeners during sickness, calamity, and old age; such fund to be managed by a separate committee, acting under a separate code of rules." When we have had an

opportunity of judging of the Society's proceedings we shall be better able to appreciate its merits, and we shall be well pleased to announce that it has effected anything for the advancement of "Gardening and Gardeners."

#### ROYAL HORTICULTURAL SOCIETY.

The weekly Show of the 4th inst. was not only gayer but better attended than any of those preceding it. Messrs. E. G. Henderson sent thirty pots of Cyclamens, consisting of eoum, Atkinsi, and vernum; Mr. Ingram, Frogmore, Ansellia africana, seedling Cinerarias, and a stand of Camellia blooms; Messrs. Lee, Hammersmith, Camellia blooms, Epacrises, Hyacinths, Heaths, and early Tulips; also a well-bloomed and handsome Camellia. From Mr. Bull, Chelsea, came *Imatophyllum miniatum*, *Cypripedium villosum*, with two fine blooms, and a small plant of *Camellia Bicolor de la Reine*; also *Dracena ferrea variegata* and *Aralia Sieboldi*. We also noticed *Schizostylis coccinea*, a new Caffarian plant with bright scarlet flowers, coming from Mr. Beech, gardener to T. Aleock, Esq., M.P., Epsom. Plants for dinner-table decoration, window-boxes, and baskets of Hyacinths and other spring flowers, were contributed by Mr. Greeves, Bayswater Road, and Mr. Lucking.

Mr. Bullen, gardener to E. Budd, Esq., Leatherhead, exhibited two good Queen Pines and excellent Sea-kale; Mr. Tillyard, fine Muscat Grapes and new Black Hamburgs, with well coloured berries; and Mr. Meredith his Black Alicante in excellent condition, though it had been ripe for eight months and three days. Of these it was stated that they had been grown in 12-inch pots, forcing was commenced on the 14th of January, 1864, and the bunches were ripe on the 1st of July. Mr. Ingram likewise exhibited seven dishes of Apples in excellent condition.

#### FAILURE OF HYACINTHS IN GLASSES.

In the last Number of the Journal "V. G. C." says his Hyacinths in glasses have failed him. You give him the probable reason. Now there is a word or two which makes me think the cause named by you is not perhaps the true one in this case. The words referred to are "the glasses have been and are kept in the window of a warm room by day."

Now last year I had two Hyacinths in glasses in the window. The sun shone on the glasses. The Hyacinths made root, and grew partly as "V. G. C." says his have done. Now they partly opened, then died. The reason to which I attributed it was that the sun made the water very hot (160° or 170°), the bulb-shape of the glass causing this I think. At all events they became so hot that you could only just bear to hold the glass. Now if "V. G. C.'s" warm room warms his glasses as they were in my case, I think that would be the probable cause.—W. N. B.

#### DOES LILIUM LANCIFOLIUM DEGENERATE?

"D., Deal" asks "Does *Lilium lancifolium* degenerate?" I think it does not when receiving a uniform cool treatment, and permitted to grow, flower, and go to rest, at its own natural season.

Under certain modes of treatment I have found them degenerate very quickly. In fact forced bulbs I have witnessed become year by year less, until they appeared to be wanting in vigour sufficient to carry a good flower singly; and, strange as it may seem, I have often noticed that those bulbs which produced the finer spikes of a past season were the least when potting was done in the proper season, and we were able to examine them. I have, however, never been driven to obtain a fresh supply by purchase, as I invariably seek the best from our plantations in the open ground. These are nice healthy bulbs when three summers old, and they well recruit our stock. It may be worthy of note that I find *rubrum* is on an average a better force than the generality of the others.

I am convinced that there is nothing so prejudicial to the constant good health and robustness necessary in this *Lilium* for a good display as strong manures, especially those which are partly decomposed, in immediate contact with the bulbs, such contact invariably causing them to become scabbed

and unhealthy. Where no undue excitement is necessary, as with the early-flowered, I have ever seen the mixture of equal parts of loam and peat produce the cleaner bulbs.

I cannot wholly endorse "D., Deal's" remarks with reference to the adaptability of these plants for exhibition. I admit having seen specimen pots staged with the flowers far inferior to those often produced out of doors under very adverse circumstances, the confined growth and stained flowers having evidently been produced by ill-directed efforts to keep them back to aid in making up a set: hence the idea erroneously entertained with reference to so pleasing a class of plants.—W. EARLEY.

#### NEW BOOKS.

*Land and Sea.* By PHILIP HENRY GOSSE, F.R.S. London: J. Nisbet & Co.

WHOEVER wishes to lead any one to study natural history by showing the beauties, the wonders, and the charms derivable from rambles inland and seaward, should induce the desired student to read this book. Not that it is suited to the young only, for we have perused every one of its pages with pleasure and benefit, although "time has thinned our flowing locks, and the few we've left are grey." Cuypp the painter throws the sunlight on his pictures so clearly, that he seems to have dipped his pencil in light and fixed it on his canvass; and Mr. Gosse has been as successful in word-painting—his descriptions are so vivid, and evince such touches of things as they were seen, that he must have a palsied imagination who cannot realise some of them. We should like to give extracts as evidence—the description of the myriads of sea fowl on Lundy Island—the scenery about Brandy Cove—the deep sea organisms—the sea anemones—the plants and insects about Babbicombe—the Torbay sponges—the Goby hunting, and many others—but we cannot spare the space. We will, however, find room for this from "A Day in the Woods of Jamaica."

"We are mounted; and now let us rapidly get over the lowland slopes, to reach the loftier regions as early in the day as possible. The sun has not yet risen; and there is a dewy freshness in the air, as the dying land-wind of the night comes off in intermittent breathings, bringing the perfume of ten thousand flowers. Here, between cliffs of limestone, where creepers festoon the rock, and the noble trumpet-blossoms of the *Portlandia*, snowy white, and each 8 inches long, hang down from the clustering foliage out of every fissure—we make our way up a steeply rising track. The cliffs on either hand soon begin to recede, and we emerge on a road between pastures of Guinea-grass, whose brightness never withers under the driest seasons. Orange trees line the road, loaded with their golden fruit; and Sops and Custard Apples, and luscious Naseberries and Guavas, are scattered over the fields. Birds have awaked: the Petchary, earlier than the yard-cock, long ago piped from the fronds of the tall *Coccoloba* Palm; and yonder we see one continuing his simple song with unabated energy, opening ever and anon, as he shifts from twig to twig, the bright golden coronet upon his head. Ha! he is not doing that for nothing. It is the expression of excitement. He has ceased to sing; watch him! A large beetle is crawling near, which is in the act of spreading his wing-sheaths for flight. Off it sails on dromy wing. The Petchary instantly makes sail too; catches the heavy prey, and bearing it in triumph to his watch-post, beats it to pieces with his strong hooked beak, and swallows it.

"Sweetly from the tangled woods of yonder hill issue the mellow notes, soft and broken, of the Merle; you would think it your own familiar blackbird by the note, and would scarcely be undeceived by a sight of the bird itself; but it is a species peculiar to us. What we here call Blackbirds are larger birds, allied to the cuckoo; impudent, clamorous, sociable creatures, with a noisy intrusive cry, like "Going away! going away! going away!" as they sail along on short, heavy wing, and long, balancing tail, close to the ground. There! we hear a flock of them now; and yonder they are in the cattle pasture, blackening the ground. They are cutting the droppings through and through, searching for maggots and worms; and for this purpose they are provided with a very deep, knife-like ridge on their beaks,

which serves them as a ploughshare. See, too! on the backs of the patient kine, and clustering around their feet, are other sable attendants; sable they look from hence, but if we were close we should find them adorned with the richest steely purple and blue-green reflections. With what business-like earnestness each searches among the hair of the cow he has selected to patronise, digging for bots and ticks; or walks round and round, with the ivory white eye turned up, scrutinising the grazing beast beneath, and now and then springing upward to seize the insect prey. Away goes one, the boat-shaped tail folded on itself, with a sharp metallic cry, which reminds you of the smittings of a smith upon his anvil. From this sound we call the familiar bird the Tinkling.

"As we proceed we hear the low sweet cooings of hundreds of Doves of various species coming from the woods. These sounds are eminently characteristic of the early day in these wooded slopes. The loud and vehement call of the White-winged Turtle-dove, 'Two bits for two!' is pertinaciously uttered; or now and again exchanged for its stammering cry of eight notes, of which the last is protracted with a moaning fall. The Pea-dove shows its plump form of purplish fawn colour, and its large melting gazelle eye, on the road before us, dusting itself almost under our horse's feet, or sits in the shadow of the groves, and coos, 'Sary coat true-blue!' And Ground-doves, no larger than sparrows, congregate in small flocks on the pasture-lands, searching for seeds of grass and weeds, and shout 'Meho! meho!' or a loud and hollow 'Whoop!'"

"Look at this ancient Silk-cotton tree! what a fine object is it, illumined in the morning sun! The enormous perpendicular spurs stand out like radiating walls from the huge trunk, looking almost as white as marble in the bright light, and throwing the recesses into dark shadow. Trace up the vast pillar-like trunk! the eye wanders up a hundred feet before it detects a branch to break the uniformity of its column; there the huge boughs spread horizontally, each one a vast tree for bulk and extent. What an aspect of strength in those contorted and gnarled limbs! How far away they carry the umbrageous canopy of foliage! And see, too, what a microcosm is such a tree as this! The hoary trunk is studded at intervals with tufts of parasitic plants of the Pine-Apple tribe; these are called Wild-pines; they do not bear eatable fruit, but their blossoms are often of great splendour. There is one now in flower: from a tuft of rigid arching leaves, which form sheathing cylinders at the base, springs a fine spike of closely-set flowers, of the richest purple and crimson dyes. Another kind has the sheathing leaves more compactly overlapping in a sort of herring-bone or zigzag fashion, whence projects a longer, looser, and more branched raceme of scarlet and yellow blossoms. There are many not now in flower, for they vary in their season of blooming, but the leaves show that they differ in species, though they possess a general family resemblance. One sort, common enough, is not at all ornamental. The negroes call it "Old Man's Beard;" the stems are very long, and as slender as wire, which form great ragged pendulous tufts, of a dull hoary grey hue.

"And there, in the forks of the huge limbs, grow enormous matted masses of various vegetation, too remote from our eyes to be identified in detail; but we discern bunches of Orchideous blooms hanging in the air; and feathery Ferns arching out their elegant tracery; and creepers running along the boughs, and what look like tussocks of wiry grass at intervals, but which are small tiny-flowered Orchids, and long, long ends of green twine hanging many yards in length, now looped up in a loose bight, now swinging in the wind in mid-air, now almost touching the earth, and dividing at their extremities into three or four smaller threads."

*A Practical Treatise on the Grape Vine.* By WILLIAM THOMSON. W. Blackwood & Sons, London and Edinburgh.

In the short space of three years Mr. Thomson's admirable treatise on the cultivation of the Grape Vine has passed through four editions. Such an event is not to be wondered at, when we consider the experience of the author and the way in which he has, through these pages, communicated that experience to others. No better test of the appreciation

in which the work is held can possibly be furnished than the appearance of the fourth edition, which contains some new matter that has suggested itself to the author since the last edition was published. We observe there are two new chapters—one on "Scalding," and the other on "Stocks for Tender Vines," which, as it is a subject that has been much agitated of late, we will transcribe:—

"Those who have paid most attention to the subject have come to the conclusion that many of the highest flavoured of our Grapes, which are at the same time the most delicate and difficult to grow with success on their own roots, will one day be grown with perfect ease when we have discovered the proper stocks for them, and that late-ripening varieties will be got to ripen earlier when grafted on earlier stocks. I have not myself proved the correctness of the latter, but have read of instances of it, and, reasoning from analogy, am prepared to believe it. Of the former I had a striking proof in the case of the Muscat Hamburg on the Black Hamburg stock. On its own roots I have not grown it above 2 lbs. weight, while on the Hamburg stocks I have had it 5 lbs. weight, with larger berries and much better finished in every way than on its own roots. I have proved the Black Barbarossa to be a most unsuitable stock for the Bowood Muscat, so much so that the fruit never ripened at all on it, while by its side the Bowood Muscat ripened perfectly on its own roots. The importance of this experiment lay in the proof it gave that a late stock procrastinated the ripening of the variety grown on it; from which one is led to infer that an early stock, like Sweetwater or Chasselas Musqué, would facilitate the ripening of late sorts inarched on them. Of the excellence of the Black Hamburg as a stock for such high-flavoured though delicate Grapes as Muscat Hamburg, and the whole of the Frontignans, I have not the slightest doubt; and I have during last summer inarched these sorts and many others on it, and recommend others to do the same, feeling confident that success will be the result."

At page 28 we find the following valuable hints:—

"I can strongly recommend the following method of planting and treating young Vines, from my own experience of it in the past season. It is probably in its details new, but it only requires to be described to commend itself to all who have any knowledge of such matters. I had a large house to plant, chiefly with Muscats, in April, 1864. I had a stock of one-year-old plants in eight-inch pots by me; I cut the rods back to 4 feet in February, and allowed them to stand in a cold Peach-house till the 13th of April, when the border was ready for their being planted; I shook all the earth from their roots, and spread them out on the soil of the border, one Vine to each rafter, and 5 feet apart, covered the roots with 6 inches of soil, and gave the whole a good watering, with water at a temperature of 150°, and covered the surface with an inch of dry soil to prevent, to some extent, the escape of the heat communicated to the border by the warm water. The Vines were just bursting their buds when planted, and instead of adopting the usual practice of stopping or rubbing off all the buds but one or two, I allowed all to grow, and tied them carefully to the wires; by this means I had in some instances ten rods to one Vine, all of which have, during the season, run to the top of the house, and partly down the back wall, a distance of 30 feet, and many of these rods are as strong as ever I had previously seen a single rod from a Vine the first year it was planted. At this date (6th January, 1865) they are not yet cut down, and the whole house is a perfect thicket of wood. I will shortly cut back all these Vines to within a foot of the front sashes, and train up two rods from each this season, for fruiting in 1866; and I need not tell those who know that a plant makes roots in proportion to its leaves, that Vines treated as I have described will have an enormous excess of roots formed in the border, as compared with others treated on the one-rod and pinching system, and that the bearing-rod they will make this year will be in proportion to the extent and vigour of their roots in the soil. I have just measured one of them that, when planted in April, was not thicker than a writing-quill, and I find that it is now 3½ inches in circumference, and has ten rods perfectly ripe to the top of the rafters, a distance of 21 feet. If, instead of permanent vigour and productiveness, an immediate return were the object aimed at, I have no hesitation in say-

ing that such a Vine would yield 50 lbs. of Grapes this autumn."

We cannot too strongly recommend Mr. Thomson's treatise as a thoroughly practical and sure guide to the cultivation of the Vine.

#### HINTS ON WINDOW GARDENING.

WITH this title, Mr. Walter H. Bosanquet has published at the price of one penny, a sheet of directions and warnings for those of "the working classes," who, living in towns, yet delight in growing potted plants either for the decoration of their windows, or for exhibition. The directions and warnings are all good, and we recommend those who wish to encourage such praiseworthy domestic gardening, to distribute copies among their labouring neighbours; for such purpose it may be had at our office for 8s. per 100.

Mr. Bosanquet is an enthusiastic encourager of town window-gardening, and there is no better aid to success than enthusiasm. He has corresponded with the Council of the Royal Horticultural Society on the subject, and the Council have appointed a Committee for arranging an exhibition of plants so grown. Mr. Bosanquet is a member of the Committee.

#### ENTOMOLOGICAL SOCIETY'S MEETING.

THE Anniversary Meeting of this Society was held on the 23rd of January, when the usual routine business was transacted, the whole of the officers of the preceding year being re-elected without opposition, and the Council elected, consisting of Messrs. Hamlet Clark, Dunning, McLachlan, Pascoe, Shepherd, Smith, Stainton, Stevens, Weir, Moore, Edward Sheppard, A. Sheppard, and W. W. Saunders. The four last-named members replaced Messrs. Bates, Grut, May, and Wallace.

The President delivered an address, in which he reviewed the Society's proceedings during the past year, as well as the general progress of the science, for which a cordial vote of thanks was passed, as well as for his conduct in the chair. Votes of thanks were also passed to the various officers of the Society.

The General Meeting for February was held on the 6th ult., the chair being occupied by the President, F. P. Pascoe, Esq., F.L.S., who returned thanks to the Society for his re-election as President, and who nominated as his Vice-Presidents for the ensuing year, Messrs. Saunders, Smith, and Stainton. Various publications of the Royal Society of London, Belgium, and Moscow, the Linnean Society of London, as well as the continuation of M. de Saussure's work on the Natural History of Mexico and the Antilles, were announced as having been presented to the Society since the last Meeting.

Mr. Brewer exhibited a minute species of Beetle, *Corticaria truncatella*, of Mannerheim, new to this country (allied to *C. fuscula*), which he had taken in some numbers at the roots of marine plants, at Worthing; also, specimens of the rare *Ceutorhynchus biguttatus*, from the same locality. He had also taken the rare *Latridius nodifer*, at the roots of plants at Hampstead.

Captain Cox sent some portions of the wood of a dog kennel, the crevices in the decayed parts of which were swarming to an extraordinary extent with the Dog Tick, *Ixodes ricinus*, in different states, accompanied by some observations on these insects, which he had succeeded in destroying by rubbing common grease over the parts of the bodies of dogs infested by them. The curious fact recorded by De Geer of the position of the male nestled on the breast of the female was observed in many of the specimens forwarded, and the young when hatched were observed to have three instead of four pairs of legs.

Mr. F. Bond exhibited, on behalf of Mr. Rich, a further series of the parti-coloured males of the common Ghost Moth (*Hepialus humuli*), from Lerwick, one of the Shetland Islands; from whence also *Bombus Smithianus* (White, *Process.* Linn. Soc.) had been received, that being the only known locality for the species.

The President stated that he had recently received specimens of the curious genus of Beetles, *Cossyphus*, from Aus-

tralia. Hitherto the genus had only been found in Portugal, Spain, Sicily, the Morea, Algeria, Calcutta, and India as far as Rangoon, but not in the eastern islands. Its discovery, therefore, in Australia was a remarkable fact in entomogeography. Professor Westwood stated also that he had recently received it from Zambesi.

Mr. Baly read a memoir containing some further descriptions of new exotic species of Phytophagous Beetles.

The President announced that the Council had resolved to offer two prizes of five guineas each to the authors of the two most satisfactory papers on questions of economic entomology, to be decided at the close of the present year.

#### AGATHÆA CÆLESTIS—EDELWEISS.

IN your Number of February 14th you say that *Agathæa cælestis* is tender "even in the mild climate of Ireland." I beg to say that I have a plant of it which has stood out of doors for two winters without any protection. It is the variegated sort.

Your correspondent "M. A. E." will not succeed, I fear, in growing Edelweiss. The inhabitants of the Tyrol cannot keep it alive long when transplanted from its native crags on the highest summits of the mountains. I do not think it can be the *Leontopodium* Mr. Fish mentions, because the flowers are white, not yellow. I enclose a specimen gathered on the mountains near Salzburg.—R. F. M., *Co. Clare*.

[In the south-west of Ireland your climate is far more genial than in other districts of the island. *Leontopodium helveticum* is the same as *L. vulgare* of some botanists. Although the corolla is not yellow, yet the dense crowd of anthers in its centre are, and would be, impressed on Mr. Fish's memory.]

#### EPIPHYLLUM CULTURE.

IN answer to a correspondent, I will commence by observing that sometimes *Epiphyllums* are found as epiphytes on the borders of rivers in the warmer parts of America, associated with epiphytal Orchids, *Tillandsias*, and other plants of half-epiphytal habit. This is particularly the case in Demerara; on the borders of the river of that name *Epiphyllum speciosum* is occasionally found as an epiphyte; but we are told on the authority of Mr. Colley, who was sent out in 1834 by J. Bateman, Esq., to explore that country in search of Orchids, that it seldom presents a vigorous appearance. Our experience of them in cultivation verifies this statement, that *Epiphyllums* are not strictly epiphytes. If not epiphytes they certainly require a similar mode of treatment, and grow well with the culture given to cool Orchids, but having no pseudo-bulbs they cannot withstand so much dryness, and yet they will resist drought for a lengthened period. A period of moisture and corresponding warmth is essential to free growth, and this should continue when once it commences until the growths have attained their full size, and a fullness of parts that approaches plumpness; and a period of rest through exposure to more light and a drier atmosphere is likewise necessary.

*Epiphyllum truncatum*, and its allied species, or those that flower from the points of the fleshy stems, and in which the branches have a tendency to droop, are cultivated in two ways—first, on their own roots; second, grafted as standards. They are handsome in either way, but I think them much more so on stems about 1 foot or 1 foot 6 inches in height. Very fine objects are obtained by grafting two scions on the *Pereskia* stock, on opposite sides, at 1 foot from the soil, two more 9 inches higher on the stock, and one 6 inches above the last on the top of the stock. The result is a pyramid 2 feet 3 inches in height. The most suitable stock is the *Pereskia aculeata*, and the most approved mode of grafting, side or tongue grafting, the scion being of such a thickness as to correspond with the stock. To secure the scion in its place the strong spines of the *Pereskia* may be run through the scion into the stock, and the graft bound rather tightly with bast, some moss being put on to secure a little moisture and exclude air. Grafting is best performed in spring when the plants are growing.

Cuttings of all the kinds strike freely if inserted in any poor, light, sandy soil. Cuttings put in in spring in a mo-

derate heat, with the soil just moist (if kept very wet they are apt to rot at their base) will be well rooted by autumn. In the spring they will be ready for potting singly into small 32's or 24's, according to their size.

We have thus two descriptions of plants, those grafted on stems, and those on their own roots; both require the same treatment, and of these young plants I will detail the culture up to the period of their becoming specimens.

The plants after blooming should be potted, for if the wood is well ripened they will bloom in the cutting state; but it is not advisable to allow this, we shall, therefore, pot them in the first week in February, in a compost of two-thirds light loam from rotted turves, and one-third turfy fibry peat, with a free admixture of sharp sand. River sand will answer as well for this purpose as the finest silver sand. Chop the compost tolerably fine with a spade, but do not sift it, for it is all the better to be open or porous. In the absence of peat, leaf mould may be substituted. Drain the pot to one-third its depth, place a little sphagnum above the drainage to prevent the finer particles of the compost being washed down, and so choking it. Turn the plant out of its pot, and remove all the old soil not filled with healthy roots, picking the soil from between the roots as much as possible. Give a moderate shift; large shifts are more injurious than beneficial, for it is better to under-pot than to over-pot this plant. Press the soil rather firm, but not tightly, and not too low in the pot, but as low as for a Geranium. If the soil is moist no water need be given for ten days, if the pot is plunged in a hotbed of 75°, which is desirable, as the cutting will strike root much sooner; but if placed on a stage the soil, if dry, should be moistened a little at the time of potting, and kept just moist until the plant begins to grow.

The most suitable situation is a house where forcing is carried on, for it will have a moist atmosphere, and be sprinkled with water of the same temperature as the house, morning and evening. The temperature should range from 55° to 60° from fire heat by night, with a rise of 10° by day without sun, but more, of course, on sunny days if accompanied by a corresponding amount of ventilation. When the plant begins to push a more copious supply of water should be given, and when growth fairly commences, the soil should be kept moist, but never so wet as to become sodden, which is too often the result of watering at stated times whether the soil is moist or dry. The want of water should be apparent before any is afforded, and then enough should be given to thoroughly moisten the ball, but the plants should be watered before the soil becomes so dry as to check growth. A moist soil and atmosphere being maintained, and the plants occasionally sprinkled overhead, they will grow rapidly, and will have made their growth by the beginning of July.

When growth is completed they are to be removed to a light airy situation, in what may be termed a warm greenhouse, where they can be exposed to the midday sun, and kept near the glass. It is presumed that they have hitherto had a slightly shaded position, yet near the glass, in the forcing-house. In the light airy situation in a cool-house they are to receive but little water, reducing it, however, gradually, and not permitting the stems upon any consideration to become limp or shrivelled. After remaining a few weeks in this situation the wood will be well ripened, quite brown-looking, and hard to the touch. If well ripened the wood rarely shrivels afterwards, even if the plants are not watered for weeks; but they should be occasionally examined, and a little water given so as to prevent the fleshy stems shrivelling. After the growths are ripened they should be kept near the glass, and sufficient moisture maintained in the soil to preserve the vitality of the plant. An occasional sprinkling overhead will tend to free the stems of dust; but a wet state of the soil must be avoided during the period of rest. A temperature of 45° from fire heat is sufficient in winter, if the soil is kept dry. Plants so treated will bloom in December if placed in October in a temperature of from 55° to 60°, and by introducing plants at intervals of a month, fine objects for conservatory decoration may be had throughout the winter. Those kept in the cool-house will bloom in April. This plant is without a rival for dinner-table decoration; specimens on 18-inch stems with a head as much through, and the points hung with hundreds of coral blooms, are much greater ornaments than those with

glass stems, the very slenderness of which is ever suggestive of insecurity.

The earliest blooming plants may be potted, placed in the forcing-house, and kept there until the growth is made, though potting is not necessary oftener than every other year; but the drainage should be looked to every season.

It will thus be seen, that for five or six months the plants are growing, and that at another period they are kept in a state of rest. Though these plants do fairly in what may be termed warm greenhouses, they require an increase of heat in spring, and unless they have the heat of a vinery they will not bloom with certainty. In a vinery where a little fire heat is given in spring and through the summer they can be grown well. Under this treatment they will bloom in spring; to bloom in winter they require the heat of a stove.

As the plants increase in size they should be potted in proportion to their growth, and if they become uneven the heaviest parts should be thinned out, and this is all the pruning they require. They may be kept for years without deterioration in small pots, by reducing the balls biennially or annually, and repotting in pots of the same size. A specimen producing five hundred blooms at once may be grown in a nine-inch pot. The finest plants are grown on the *Pereskia* stock. Plants on their own roots seldom attain more than a foot in height.

Such is the mode of treatment I have adopted with good results, and it is much to be desired that those who have been successful in this branch of culture, would make known their practice through these pages, for of all plants none are so gorgeous, nor so little cared for at the present time, as the Cactus family. In fact, we generally see them better grown and blooming more freely in cottage windows than in the best garden establishments. About thirty years ago these plants received the care which they merit, and the indifference to them which exists at the present time can only be attributed to the introduction of so many new plants, though less useful and ornamental. Dry stoves were common then, but now there is scarcely one to be found in the land.—G. ABBEY.

#### A RIBBON-BORDER.

I HAVE a ribbon-border 40 yards long and 6 feet wide; the background is common Laurels. I thought of planting it thus—Back row, No. 1, *Perilla*; No. 2, *Christine Geranium*; No. 3, *Brilliant Geranium*; No. 4, *Shrubland Pet Geranium*; No. 5, and front row, *Cerastium tomentosum*. I dare not plant *Verbenas* or *Lobelias* as they suffer so much when quite young from the rabbits. Last year I had *Lady Middleton Geranium* next the Laurels, then *Perilla*, but I was assured that *Perilla* ought to be next the Laurels.—R. B.

[If you keep *Perilla* low enough we certainly should prefer strong plants of *Lady Middleton Geranium* next the sombre Laurels. Discarding as you are obliged to do, *Verbenas* and *Lobelias*, we would rather plant thus—*Lady Middleton Geranium*, *Perilla*, *Christine Geranium*, yellow *Calceolaria* (*Aurea floribunda*), *Brilliant Geranium*, and *Cerastium tomentosum*.]

THE ACTION OF AROMATIC PLANTS ON SILKWOOMS.—M. E. Faivre details the following experiments to the French Academy:—"Silkworms exposed to the action of wormwood, but not in actual contact, were very much excited, they tried to get away. The pulsation of the dorsal vessel was augmented and their bowels purged; in a few hours they were dead. Fennel produced similar results on the nervous system, and a marked one on the secretions. Balsam-tansy acted still more powerfully, even killing the sick worms, and causing the healthy ones to emit their silk. Common tansy was less violent. The effects depend upon the quantity of the odoriferous herb employed, and on the condition of the silkworms. When healthy worms were supplied with mulberry leaves and exposed to the aromatic, they ate their food, and made cocoons which were considered of superior quality."—*Dublin Medical Press*.

[These facts suggest that gardeners should try the effect on their enemies, the caterpillars, of syringing them with water in which tansy and other strongly scented herbs have been soaked or boiled.]

GLAZING WITHOUT PUTTY.

IN addition to the various suggestions for carrying out this practice which have already appeared in our pages, we have some woodcuts and notes from Mr. Messenger, horticultural builder and engineer, Loughborough.

The glass used for this glazing has the sides turned down, as shown in No. 1, which conveys the water into small gutters made of lead, copper, zinc, or iron; or the sash-bar itself is made with a gutter in it.

The mode of securing the glass down to the gutter, is shown by section No. 2, which is by a screw passing through

Plan.

Glazing which requires no putty to make it waterproof.

a brass plate and india-rubber pad into the wood or metal bar; the india-rubber slightly pressing upon the two sides of glass keeps it in its place.

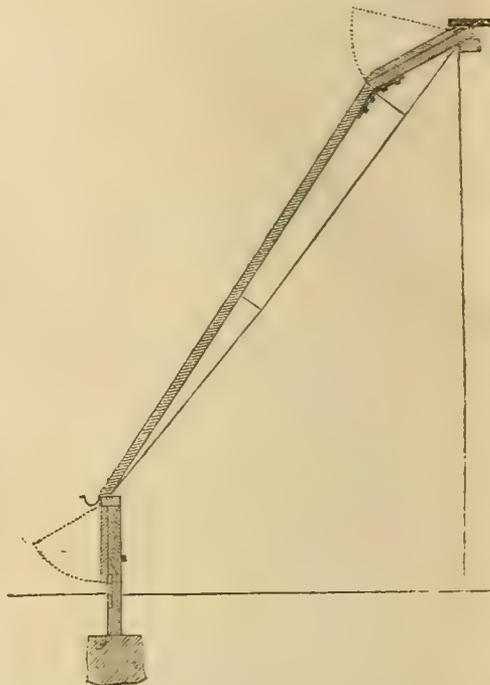

The plan shows the brass plates and shape of the glass, which is so arranged as to convey the condensed vapour into the gutters internally, as well as the rain externally.

The first cost is rather more than that of ordinary glazing, but is much more than compensated for by the following advantages—viz., no paint is required, saving the usual periodical ex-

penditure of painting once in every two years; any handy labourer can replace a square of glass when broken; all annoyance of pieces of glass and putty falling amongst plants, &c., during repairs is avoided; also the appearance is far superior, and minor advantages would be experienced by its use.

Where it is

necessary to make it air-tight as well as water-proof, a back putty is used, but which is never exposed to the

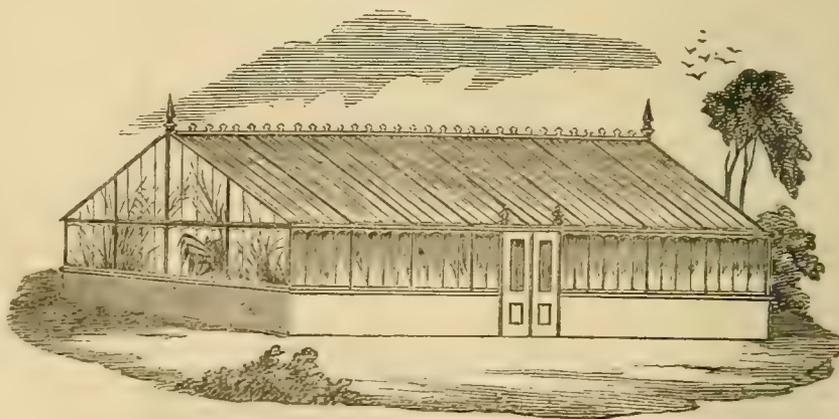

action of the weather, so that it is as durable as the glass itself.

The above is a section of a very simple and effective structure for covering

Peach, Fig, or Apricot-walls, and which could, if heated with hot water, be used with advantage for a very early vine-ry. It is, in fact, when unheated, a lean-to orchard-house.

The annexed is a greenhouse erected by Messenger, at Goggerddan Hall, the residence of P. Lovedon, Esq., of Aberystwith.

SEWAGE IRRIGATION.

WE have received a note from an intelligent correspondent, who, like many other persons, seems to have derived a very erroneous impression of the value of sewage when applied in small quantities. He observes:—"The subject of irrigating grass pasture with liquid manure is rather new. I have about ten acres of grass—four of old, six new-sown last spring. I have also a large cesspool. How can I use this manure? Where purchase the cart, where the pump? Any information on this subject given directly to me, or by an article in your Journal, will be thankfully received."

Our reply must be that we cannot advise any one to

employ a watercart to spread the sewage over grass. Such a sprinkling is of little perceptible use. We must not be led astray by certain schemes, lately announced, for squirting the water over the land in small quantities. If the tank receives the sewage of only one house that will be best applied to not more than one-eighth of an acre of grass. The gardener knows that sewage is an admirable liquid with which to water his kitchen-garden plants; but he is well aware that to derive any material benefit he must give them a good soaking—a small shower of it is useless. On the sewage-irrigated meads of Edinburgh the grass is tho-

roughly soaked about every eighteen days, and these meads have for many years been let at an annual rent of from £20 to £30 an acre. At Croydon about 4000 to 5000 tons of sewage per acre are used every year, and this produces about 32 tons of grass, worth on the ground £1 per ton. Lord Essex, Mr. Mechi, and the Rugby Commissioners have

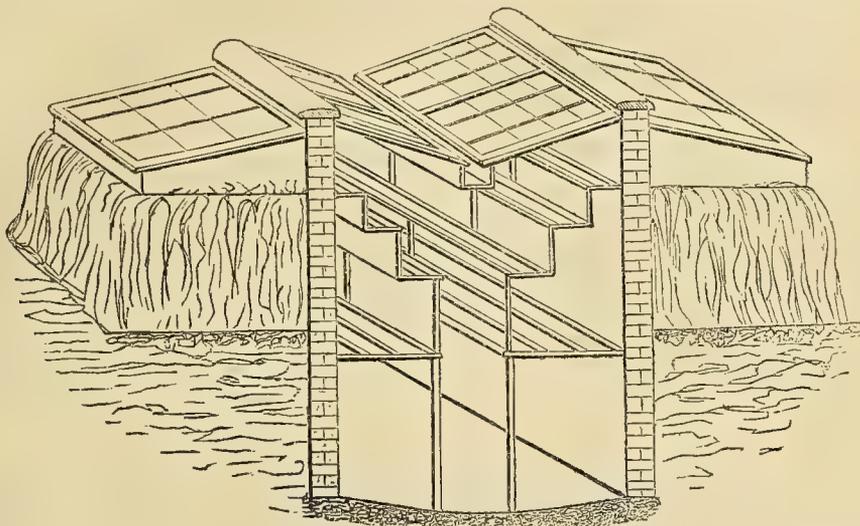

all given up using sewage in small quantities for grass. If you can arrange so that your house sewage can be directed on to your land by its own gravity, well and good, or by the use of a common lifting iron or wooden pump; but it would be a profitless effort to use a cart.

WINTERING PLANTS WITHOUT ARTIFICIAL HEAT.

IN No. 196, "ISLE OF WIGHT" made a suggestion with which I was much pleased, and at the time I resolved to give you a sketch of a pit which might be rendered useful all

the year round; press of business has not permitted me to do this sooner, but better late than never.

I propose to sink the pit—say 5 feet (this, however, must

Pit for wintering plants.

depend on the nature of the ground), and build a nine-inch wall above ground—say 6 feet high, against which the dung for hotbeds could be stored. This would keep the pit warm above ground, and to prevent water filtering into the pit, a

bed of concrete should be formed under the dung. The form of the roof will give plenty of light without the glass catching the wind.—GEO. K. GEYELIN, C.E., London.

HARDY FERNS:

HOW I COLLECTED AND CULTIVATED THEM.—No. 11.

IN my last number I brought my Fern collection to an end; but I feel as if I had yet a last word to say—a small, very small sum to cast up of the amount of work, or rather play, that I have done in the Fern papers, in which I have so pleasantly wandered back through familiar scenes and amongst familiar friends.

I have mentioned all the species of English Ferns, with the exception of the *Trichomanes radicans*, which, being an Irish Fern, hardly forms an exception. I have never found *radicans*, have never grown it, and have never but once seen a really thriving plant of it. I have now in cultivation all the species of English Ferns, excepting the two *Woodsias*,\* the *Asplenium germanicum*, and the *Hymenophyllums*. They consist of

*Adiantum capillus-Veneris*, with the Dunraven variety, if variety it be.

*Allosorus crispus*.

*Asplenium trichomanes, viride, fontanum, ruta-muraria, lanceolatum*; *Adiantum nigrum*, with varieties; *septentrionale, marinum*, with Cornish variety.

*Athyrium Filix-femina*, with varieties.

*Blechnum spicant*, with varieties.

*Botrychium lunaria*.

*Ceterach officinarum*.

*Cystopteris fragilis*, with varieties.

*Cystopteris montana*.

\* I may also now add the *Woodsia ilvensis* to my list of Ferns under cultivation, a plant of this rare and delicate Fern having been kindly presented to me by Mr. Mitchell, of the Glen Nursery, Bacup, Lancashire.

*Cystopteris elfina*.

*Lastreas Filix-mas*, with varieties; *cristata, thelypteris, oreopteris, rigida, dilatata* (with varieties), *recurva*.

*Ophioglossum vulgatum*.

*Osmunda regalis*.

*Polystichum aculeatum*, with varieties, *angulare* (with variety), *lonchitis*.

*Polypodium vulgare*, with varieties, *dryopteris, phegopteris, calcareum, cambricum*.

*Scolopendrium*, with varieties.

So the sum I have to add up of what I have written about seems very small, although it has taken ten years to collect together the parts of which it is composed. But what amount of figures would tell of all the happiness that it has been to myself and others?—the happy days, the merry hours—hours of pain forgotten and of sorrow soothed—hours in which, when alone, the soul, winging itself from the material things around, has flown up on bright thoughts to the blessed world whence it came. Who could number up these thoughts, or count the circle of blessings that has widened out from them?

A friend of mine, once walking in Yorkshire during a severe drought, met a labouring man, and in passing said, "What a blessing a shower would be, my friend." "Ah!" said the man in reply, "it would let loose a many prisoners."—The imprisoned seed, parched and thirsty, waiting, bound in the fetters of its husk—the million buds on every tree, all waiting for the genial shower to loose their prison-bonds and set them free. What beautiful thoughts the good God

must have given this poor labouring man ere he could have framed his simple touching speech!

Bulwer says that the face of Nature is the only face that as we grow old never changes to us. Friends grow old, change, and pass away; but the old Oak of our youth is the old tree still. The hill has still the same shadows, the valley the same musical river. Their voices speak the same truths in the same tones; the vexed murmurs of the world touch them not: they praise God day and night, though a man in his ungrateful egotism will not listen, will not echo their simple song.

Every created thing has something good and pleasant to say to us if only we will listen aright—some beauty to be revealed if we will seek for it—some wondrous exhibition of skill, greater and more perfect than can be shown by the greatest living man; and, as we search and look, the voice, the beauty, and the skill will all lead us up to that high communion the Most High encourages His children to hold with Him. A few more words upon the Ferns, and I have done.

Of all that I have named the *Aspleniums* are the most difficult to manage as a race. They one and all hate stagnant moisture. They require light, and sun, and shade—shade for the roots, and sun for the fronds. *Lastreas* are less difficult; they do not need sun as a necessity—they will grow in damp and shade. *Cystopteris* is a very easy Fern to cultivate; it will suit itself to almost any locality. *Osmunda* requires damp and shade. *Polystichums*, and *Polypodiums*, and *Allosorus* need sun. All Ferns must have good drainage. I always mix good garden earth with the soil of old banks, the *débris* of trees, &c. I water nearly every day during the summer.

Do not be afraid of Ferns. They like being moved and divided, and will forgive almost anything but neglect.

Never plant a Fern upon a rock or stone; there must always be depth of soil with drainage beneath. If a Fern does not do well in one situation try it in another, but never see a plant looking unhappy without trying to find out the cause and seeking to remedy it.

Before these pages are printed I hope to be hunting Ferns in the neighbourhood of Naples; and if the Editors of THE JOURNAL OF HORTICULTURE will kindly give me a corner I shall hope to tell my experiences when I return. Till then adieu!—*FILIX-FEMINA*.

### STRAWBERRY PLANTS NOT FLOWERING.

I HAVE some very strong healthy plants of Keens' Seedling. I treated them in the usual way: had them piled up in ashes until the last week in January, then started them for forcing in a heat of 45°, giving a rise of from 5° to 10° with sun. The plants are stronger than those I have grown before, and gardeners that have called to see me thought, as I did, that there would be a good crop from them, but there is not a blossom out of a hundred plants. Can you give me any information as to the cause of this failure?—*A SUBSCRIBER*.

[You say nothing of the size of the pots which contain your very luxuriant plants. We suspect that your plants are rather too strong, and that the buds were not sufficiently matured last autumn. We do not think our Strawberry plants will be quite so fruitful as usual, as we notice several pots coming blind, but we attribute it to the want of water in summer and autumn. The more luxuriant the plants the more ripening do they require in autumn.]

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

THE preparation of the various quarters destined for main crops must be persevered in whenever the soil is dry enough to admit of being trodden on without being too much consolidated. This is of great importance in the case of heavy soils; and those who have such to deal with should take advantage of every dry day that occurs. On such soils, too, it will be advisable to defer sowing main crops for a week, or even a fortnight; but on light dry soils the sooner the main crops are sown the better, because such soils are most liable to suffer from drought should it occur, and therefore

the sooner the crops are well established the better they will be able to resist its effects; if, on the contrary, the season is a wet one, they will be in the best possible condition to profit by it. *Beans*, sow the main crops, regulating the quantity by the demand. *Broccoli*, a small sowing of Grange's true Early White made now will come in useful by-and-by. *Cabbages*, make a sowing of the true Drumhead Savoy, also another patch of early Cabbage, and Red for winter supply. *Cauliflowers*, prick out the young seedlings on a warm border or on a gentle hotbed, and shelter them for a time with hoops and mats. *Celery*, the first sowing must be pricked out as soon as it can be well handled, and another sowing made of both Red and White. *Onions*, the principal crop should now be sown, and as it is a crop of some importance we offer a few words of advice. The ground having been trenched and ridged during the winter, is allowed to remain in that condition until the early part of this month; it is then levelled down, and marked out into beds 3½ feet wide with alleys 15 inches wide. Before the seed is sown the beds are raised 9 inches above the ordinary ground level by soil from the alleys, and when the beds have become perfectly dry the seed is sown and the beds trodden twice over by the feet until they appear as hard as a gravel walk. A very thin coating of soil is then strewed evenly over the whole, and finally the roller is passed over the bed. The narrowness of the beds enables the operator to weed clean with facility and without injuring the plants. Plants thus situated have a greater depth of soil than usual, and grow with greater sturdiness than those highly manured, whilst the great elevation of the beds enables a warm July sun to penetrate a considerable depth into the earth, slightly checking late growth, and, of course, inducing early bulbing. Take advantage of dry days to stir the surface of the ground between growing crops, and to prevent weeds from making their appearance.

#### FRUIT GARDEN.

Protect Peach, Apricot, and other choice fruit trees from spring frosts. Finish pruning and nailing as soon as possible. See that newly planted fruit trees are properly staked and mulched, and after high winds it is necessary to look over them and press the earth gently round the base of the stems. All danger of very severe frost being over, Figs may have the coverings completely removed and be neatly pruned and nailed; do not crowd them with wood. Finish planting Raspberries, also pruning. Let all the old leaves be cut away from Strawberry-beds, removing all runners, &c.

#### FLOWER GARDEN.

All trained trees and plants should receive attention. March winds are often destructive when the precaution of renewing old stakes and strings rotted by the damps of winter is neglected. A pretty floral effect may be obtained at an early season with *Narcissus*, *Hyacinths*, and *Heartsease*, which may now be planted for the purpose. *Anemones* and the single *Wallflower*, last summer's seedlings, will shortly bloom; and in large masses the effect of their rich golden blossoms is magnificent. *Hollyhocks* for late blooming may now be planted, as it is best where they are grown extensively to make two or three plantings in order to insure a succession of bloom. These showy plants are very suitable for long lines, parallel with straight walks, walls, &c., where they produce a noble effect. If edgings are required to flower-borders they should be planted as soon as possible. *Box*, *Daisy*, *Chamomile*, *Thrift*, *Pansies*, the *Gentianella*, &c., are all used for this purpose. Let *Box* edgings be cut forthwith. Plant out *Carnations* and *biennials* in general, and let all *perennials* be removed without delay. Look to the sowing of *annuals*, also *shrub* and *tree* seeds. Finish the laying of turf, and get all alterations carried out at once. Let *Roses* in general have a pruning immediately. Those intended for late blooming must be pruned late.

#### GREENHOUSE AND CONSERVATORY.

Examine the soil of such plants as the different kinds of *Acacias*, *Templetonia*, *Genista*, *Cytisus*, *Grevillea*, *Banksia*, *Myrtle*, *Brugmansia*, *Olea*, *Nerium*, *Eutaxia*, *Goodenia*, *Virgilia*, *Indigofera*, the varieties of *Cactus*, and others that may have been resting, to see that the drainage is efficient, and that no plant is rendered unsightly for the want of timely watering, pruning back, or stopping. Many an old corner requires routing out. Stop any unruly, rank-growing

shoots of Camellias that are taking the lead on those plants whose blooming season is over, and endeavour to keep a uniform growth both of wood and blossom-buds for the ensuing year. Ericas to be top-dressed or repotted. Commence syringing on a fine morning such plants as are freely making their growth, and those that have lately finished flowering. Tropæolums will require attention. Pelargoniums and Calceolarias will require increased pot room. Apply tepid clarified manure water to those well established in their pots, if healthy and showing flowers. Do not omit slight but frequent smokings of tobacco. Fuchsias for general decoration, or as single specimens on grass, should be brought forth from their hiding places without delay, and introduced, if there be room, to a warm end of the greenhouse. These who have bottom heat to spare, and desire very large specimens, may select some of the best plants, disroot, and repot them, and plunge them in a bottom heat of 75°.

## STOVE.

Some of the plants which have been blooming for many weeks, and which are exhausted, should be cut back—such as Euphorbia jacquiniæflora, Gesnera lateritia, Geissomeria longiflora, Eranthemum pulchellum, Justicia salicina, Linum trigynum, Poinsettia pulcherrima, &c. The plants of Poinsettia, Euphorbia, Clerodendron, Aphelandra, Gesnera, &c., that have previously been cut down, and are now breaking, should be shaken out and repotted in good fibrous turfy loam, coarse sand, and a portion of charcoal. Prick off carefully into small pots as they appear in the store-pans or pots the various kinds of Achimenes, and put in another batch, likewise various Gloxinias, they delight in a moderate bottom heat at this season. Continue to increase the heat and humidity in the case of Orchids, and see that plants of Gongoras, Stanhopeas, and some of the beautiful Dendrobiums that are now making their season's growth, are not suffering from want of sufficient moisture. It is sometimes found essential to soak them once or twice in a tub of tepid water, and if a portion of clear cowdung water is added thereto it will do much good. Syringe carefully about the blocks and baskets that have plants of Vanda, Saccolabiums, Sarcanthus, &c., growing or adhering to them.

## PITS AND FRAMES.

Those who have not as yet attended to the propagation of plants for bedding-out must now begin with all possible speed to put in cuttings of Salvias, Petunias, Fuchsias, Verbenas, and Scarlet Geraniums, so as to have good plants for bedding-out in May. Pay attention to watering and topping back weak and straggling shoots, so as to form robust, bushy plants. Dahlias should be started. — W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

OUTSIDE, the ground is still too wet to permit of much being done. Put more Rhubarb and Sea-kale in Mushroom-house, and cleared Mushroom-beds. Raised bed intended for Cucumbers, under a frame. Our frames are shallow, some 10 inches in front and 16 inches at back. We raise the bed high enough at the back to give pretty well 2 feet of a slope to the front of the frame, and our boxes being so shallow we make a trench in the middle of the bed from 26 to 30 inches wide and 16 inches deep for soil, placing an old slab back and front. This trench prevents any likelihood of burning the roots from a too violent heat beneath, the confining the roots by the boards prevents too much luxuriance of growth, the heated leaves close to the boards give plenty of heat to the soil, the packing some earth close to the sides of the frame prevents steam passing in from linings, and as the frame sinks with the bed there is no necessity for regulating the height of the plants from the glass, as the soil on which they are trained and grown is just of the right height for the foliage. We thus escape all the trouble of frequent earthing-up, merely giving a little rich top-dressing when there is any sign of deficiency of vigour. Though wood is a bad conductor, still it does conduct heat; and making the bed wide enough at first to permit of banking-up to the top of the frame, or nearly so, secures a dry heat against the boards for the atmosphere of

the house which can be made moist at will by dewing the boards. After trying many modes we follow the above when we can, as being on the whole the most economical as respects time, labour, and material.

Thinned Lettuce among Radishes, which latter are now coming in nicely. Gave plenty of air to those in Carrot-bed, just above the ground, to prevent their coming with long necks. Watered with manure water strong Cauliflower in pots in orchard-house. Sowed Cauliflower, a pinch of Cabbages, and Celery in mild hotbed. Stirred up the soil among Cauliflowers under hand-lights, exposed the heads of Celery in beds to prevent rotting. Do not think we have had half a dozen of run or rotten heads as yet, and the heads are very sweet notwithstanding the dry weather and no water to which they were subjected. But for the shading with evergreen branches, it would have been all up with them. Prepared, also, a three-light end of a pit for Cucumbers, where they can have hot water. This is all very well where fuel is cheap; but if we did not manage to raise some beds under frames, &c., even with tree leaves chiefly, we do not know what we should do for dressings for the kitchen and flower garden.

## FRUIT GARDEN.

Continued work very much the same as last week. Pruned out of doors in suitable weather; daubed with lime, soot, and anything nasty, to keep off birds from buds. Owing to the snow and frost, we were privileged with clouds of larks, that did us little harm except stripping, as if with a cutting iron, the outer leaves of Broccoli, &c., leaving the hearts mostly untouched. Partridges, now pairing, did the same office for us in the very cold weather. They and pheasants are sometimes troublesome enough, but they are nothing to the four-footed intruders in the shape of hares and rabbits. Even in their case the gardener, in general, where game is an object, should try every deterrent method, without resorting to the gun. The report not only breaks in on the peacefulness that should pervade a garden, but the passion is so apt to grow from what it feeds on, that not a few most estimable men as gardeners have got into great trouble from becoming too fond of shooting. We should never forget that, though it is praiseworthy to be anxious for the well-being of all under our charge, the gamekeeper ought to be equally anxious about the safety of his protégés. Where pheasants are numerous, wire guards may be necessary for Peas, before they are 4 inches in height. After they are staked, partridges and pheasants will do them less harm; but then the sparrows will come like locusts, and rip up the pods you want to send to table. Bat-folding among the shrubs would thin these birds now. Small threads, either white or black, run among dwarf trees and bushes, will help to keep them from the buds; and such threads, run along with little pegs a few inches—say 3 at first—above rows of seeds, will also keep them off. We thus saved most seeds last season, except Beetroot, Prince's Feather, and Love-lies-bleeding. The red seed-leaves of these things seem to be an irresistible attraction. It is best to sow them, in such circumstances, where protected, and transplant when a good size.

We have seen no more, as yet, of our enemy the brown beetle in the Peach-house, though we have looked anxiously for him every day. A few Black Prince Strawberries have been very fair for flavour, but, if they had little sun, they had plenty of air. The bulk of plants are much smaller than usual, and the Keens' do not come so generally good as usual, some pots showing little or none. The next lot will likely be better. We fear the buds of some were starved last summer and autumn before the rains came. We are now obtaining good reservoirs of water, and hope we shall never again have to pack plants behind sheds and in thick woods, merely that they may be shaded, and thus kept alive, whereas in the sun they would have been dried up and killed outright. The Black Prince Strawberry plants have hardly had a miss in a single pot. Of course all pots that do not show bloom should be turned out at once. In all early forcing we generally used to reckon on something like five per cent. of blind pots, but our early Keens' will be beyond that this year. Succession crops generally come with few or no failures. From several private communications, let us again urge on our friends not to plunge established pots in a hotbed before taking them into a house

heated by fire heat. If they choose now to take plants out of the ground to pot, as we will be obliged to do in a month or so, a little bottom heat, whilst the tops are kept cool, will do them good, but the bottom heat should decline as soon as the roots reach the sides of the pot.

In the *orchard-houses*, in bad weather, syringed all the houses with hot soap water—walls, woodwork, and trees—and then painted the trees with a paint made of clay, soot, lime, soft soap, and sulphur; and, when trees are fresh fastened to the wall, will use a thin wash of Gishurst. We may mention here that the wash of Gishurst for the Peach-house was strong enough to injure a few young shoots. We may also mention, in answer to many inquiries, that Gishurst is a capital thing used sparingly, and especially for amateurs, as it enables them to have a good wash without the trouble of mixing; and, if soaked and dissolved in water some twelve hours before using, the liquid loses its offensive smell for syringing, &c., and at the same time loses nothing of its insect-repellent properties. We could also speak favourably of Parmentier's and other washes; but, at the same time, truth compels us to say that the best remedy is to keep away insects by health, vigour, and unceasing attention, and that, as to paints over the wood, clay alone, or clay, sulphur, and soft soap, are just as efficacious in daubing up insects and their eggs as the finest compositions, with learned names, sent out in box or bottle. A little tobacco juice in the mixture will do no harm; but much, if hot, may do so. A little lime, if there is anything like moss or fungous growth, will also be useful; and in extreme cases a little *nux vomica*, cold. All such washes, in moderation, are safe, if cold; but if lime and sulphur, and *nux vomica*, are boiled, &c., the mixture ceases to be mechanical, and, used hot, may prevent all further need for using it again. Even lime and sulphur, mixed into a paste, and used as paint, are very different from lime and sulphur, heated or boiled together. By the latter mode a most powerful acrid liquid is produced; so that if a pound of lime and a pound of sulphur are boiled in a gallon of water, one quart or gill of the clear liquid, when cool, would be strong enough to syringe with twenty gallons of water. White hellebore is also as destructive to many insects as snuff, and is much cheaper. Sulphur, as we have often stated, is chiefly useful, like lime, for destroying mildew or fungus, and for the fumes which it throws off in a temperature of about 160° or 170°, either with artificial or natural heat.

To return from this digression. Before tying the trees in the orchard-house, on the back wall, we have, after the washing, the old colour, however, remaining firm, coloured afresh the greater part of the wall, making fresh lime the chief constituent. In such lean-to houses, with so much light from the squares of glass between the sash-bar rafters, which squares are 20 inches by 12 in depth, a white wall would throw back too much heat for the well-being of the trees, before the foliage was fully expanded. We therefore darken the lime considerably, and this season we have added a good proportion of sulphur. Our bricklayer, who generally puts it on, is very particular in having the lime mixture fresh made and smooth to work with the brush. When the lime is slacked, it is worked with sufficient water to pass, by means of a brush, through a very fine sieve, all grit, if any, being rejected. To about four gallons of this are added three or four pounds of sulphur, previously made into a soft paste, and about two quarts of blueblack in the dry state, also mixed with enough water to make it into a smooth homogenous paste. These two articles are mixed with the smooth lime-wash, and the whole is put on rather thin, and looks black at first, but dries sufficiently white. Hot water is better for slacking the lime than cold, and the colour stands much firmer on the wall when so slacked. The sooner it is put on the better. If enough of mixture is made to take two days to put on, or if the job is left, the second day's washing will not be so firm as that of the first, and it will be apt to be a shade lighter in colour.

We have had so many inquiries how to take off the offensive white glare from limewash, that we may be excused for the above minutiae. Such a toned wall neither distresses by its brightness, nor saddens by its gloom; and instead of reflecting the most of the rays of heat and light so as to make everything uncomfortable near it in bright sunshine, it just reflects enough, and also absorbs enough to warm the wall,

so that it may radiate back a portion of the heat thus absorbed during the coldness of the night.

Fruit trees may still be planted, and after such a winter will do little worse than those planted in the autumn. It would be well to cover the ground with rough litter, move it aside on hot sunny days, and replace in the afternoon. In all cases where present labour is an object, a mound of fresh soil may be given to each tree.

#### ORNAMENTAL DEPARTMENT.

The snows and heavy rains have prevented much out-door work, except rolling the lawn and sweeping the walks of leaves, twigs, &c., and examining bulbs of all sorts to see if they were securely fastened in the ground. Also, the same as to all fresh-planted shrubs and trees. All planting of this kind should be finished as soon as possible. In all favourable weather proceeded with planting for timber and cover, and this work now should also be finished without delay. The frost and the snow have rendered the hares troublesome, independently of tarred string, &c. Evergreens and other shrubs may be planted until the buds for the fresh shoots begin to swell.

In hotbed or pit, Lily of the Valley, Deutzias, Roses, Rhododendrons, and bulbs may now be more easily forced into flower for the conservatory. A little bottom heat will cause them to come better after the pots are crammed with roots. Hyacinths, Tulips, Narcissus, &c., in rooms, should have all the light possible.

Out of doors we shall prune all the hardier *Roses* as soon as the ground is drier, cutting Moss, Provence, Gallica, and the less vigorous-growing Perpetuals pretty well in. All strong growers, of climbing habit, Banksian, and Briars, do best when the small wood is thinned out, and the long well-ripened shoots left nearly their full length. From every bud a short shoot will come with clusters of flowers. It is best to cut out these old shoots in autumn, and depend on young, middle-sized long shoots again. When such *Roses* are used against walls or fences, they may be spurred in for years like a Vine, merely by thinning out the small spray from each node of buds in the beginning of summer, and cutting back to one bud in winter or early spring. Bourbons, Teas, and the more tender Chinas, should have the pruning deferred until April. Teas laid in by the roots in a sheltered shed, should now have the moisture at the roots examined, and the covering at the heads reduced. If mild weather continue the same lessening of protection should be given to those left in the ground. Now is a good time for grafting on stocks well-established in small pots, and then placing them in a mild hotbed. The sooner Briar stocks are pruned-in and planted the better for budding in summer.

Rockwork and collections of Alpines, and the tender herbaceous plants, and even Wallflowers, &c., will want seeing to and firming, after the frosts and boisterous winds. Daisies and Heartsease may also be divided, using a little fresh soil round them. The smallest root pieces of the latter will do better than cuttings. Ranunculus may also want firming, also bulbs in general, and mice should be kept from them. Pinks may be planted, and plenty of air given to Carnations, Auriculas, Polyanthus, and the finer Primroses.

Put in a good many cuttings of Verbenas, Petunias, &c., as we like young plants better than old ones. Went on with Lobelias, &c., but the methods we have frequently detailed. Those made at present we put into vessels of some sort, but by-and-by we will dibble the cuttings at once into sandy soil upon a slight hotbed, and take the glass off them as soon as they are struck. We are so crammed at present that we can scarcely turn ourselves, but in a few weeks we will put a great many things out of doors under temporary protection.

Kept on potting Fuchsias, Geraniums, tying-out Pelargoniums, and giving larger pots to successional Primulas, Cinerarias, &c., and if we had a fair day would fill a shed behind a greenhouse with large plants of Scarlet Geraniums, that we may prune a part of our last vinery, the Grapes in which will soon be over. We have a great many bedding plants in it already, but we want the whole floor, stage, and shelves, to clear the Peach-house of all bedding stuff, or the most of it. The trees are coming nicely in bloom, average night temperature close on 50°, heat applied to raise it to 55° and 60° during the day, and if sun come, of which we see little, we will with a little early air, allow it to rise to

10° or 15° more, and shut up early. Except on shelves of Strawberries, all shelves, stages, and floors, are as thickly set with plants as if these were so many grass blades.

Gardenias will now like dearly a little bottom heat in a dung or tan-pit. Ixoras will also be better of being plunged and the leaves examined for thrips or green fly. What is worse than either is mealy bug, and purchasers should be careful in selecting from clean stocks; only a very few of them are sufficient to overrun a place, and they will not confine themselves to plants, but get into every cranny of the brickwork, woodwork, &c., where scarcely any application will reach them. Dipladenias, Allamandas, &c., would be the better of bottom heat after repotting. In small houses it is advisable to pick away a good portion of the old soil, and then repot in the same sized pot, using fresh fibry soil. Clerodendrons that were pruned back and have now broken half an inch or so may also be repotted, shaking away a good portion of the old soil, draining well, giving fresh soil, and placing in bottom heat; if the shoots come too numerous thin out the weakest when from 2 to 3 inches long, and they will soon strike in a hotbed. Such tubers as Gloriosa superba, &c., should also now be taken from the pots in which they have rested in a rather dry state. The best time for fresh potting, is when the buds show signs of moving, draining well, and using fibry peat and loam, lightened with silver sand and nodules of charcoal. Gloxinias now beginning to push should either be top-dressed with rich compost, or the most of the earth removed from the tubers and these returned to similar or, at first, smaller-sized pots. They dearly like old dried cowdung mixed with the compost. The same may be said of the fine-leaved Begonias which have been set under stages, &c., to dry and the leaves to fade during the winter; when a little water is given to them, and they are placed in a temperature of about 55° or 60°, they will soon break, and then may have their rhizome-like stems separated, the most of the old earth shaken away, and rich light soil given. Achimenes and Gesneras, placed some in heat to start them; Justicia, flowering Begonias, and especially the pretty fuchsioides, Eranthemums, Poinsettias, &c., do best for small houses if the cuttings are struck now and in the beginning of next month, and the old plants thrown away.

We have taken care to keep a nice lot of soil dry, under cover, which is half the battle; and for all these tender plants we like it to be heated over a furnace, or in some suitable place, before using it. We have given all the air possible to bedding Calceolarias that are still in the pit, in which the cuttings are thickly dibbled out in October and November; but we must harden them off for turf-pits, as they are now standing too thickly. We forgot to say that, as a measure of precaution, we drew all Verbena cuttings through weak tobacco water, and were careful that the quick hands that took them off should also use the eyes quite as quickly, that every piece taken off should make either one or two cuttings, without a bit or a joint being wasted. It always shows great carelessness to see a bit wasted at the cutting bench at this season, after having occupied room all the winter. We also took the opportunity of stacking some very fibry turf 2½ or 3 inches thick. This, in bad weather, if we are scarce of pots, we will cut into pieces about 3 inches square, scoop out a hole in the middle, for more than half the depth, and use these for some Geraniums, and other things that do not plant well without a ball. We have placed a box on the material which covers part of the Vine-border, and therefore will have a little heat; and if these little bits of turf, each with a plant and fine soil in the hole, are placed there until the roots are coming through the turf, they may then be moved to leaf mould and soil in a Celery trench, and have a little protection there, until finally turned out. This is only a sample of what people must do if they have to make the most of, and obtain the most from, little room. It would not do to leave such turf pots in the mild hotbed, as the roots would get beyond all bounds; but when turned out, after being merely started, the root will cluster all round the turf like a wig, and be ready to extend wherever they have the chance.—E. F.

TRADE CATALOGUE RECEIVED.

Sutton and Sons, Reading.—Farm Seed List, March, 1865.

COVENT GARDEN MARKET.—MARCH 4.

The supply has improved, but prices are fully maintained. Pines continue scarce; Grapes and Pears are sufficient for the demand; and with Apples the market is overstocked, but good kinds for the dessert are not over-abundant. Savoys, Brussels Sprouts, and other Greens, are not over-plentiful. English forced Potatoes may be had very good at from 2s. to 3s. per pound; foreign ditto 6d. to 8d. Salads, &c., come in daily from the continent. Artichokes and Peas have arrived from Lisbon, the latter selling at from 12s. to 15s. per quart.

TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

ERICA HYEMALIS and E. GRACILIS.—FORCING PELARGONIUMS (*An Old Subscriber*).—When the Ericas have done blooming, pot them in the course of March in a compost of sandy turfy peat, draining the pots to one-third their depth, and keeping the neck of the plant slightly elevated. Be careful not to disturb the roots more than necessary, picking away the old drainage and the soil not filled with healthy roots. Give a moderate shift, large shifts are injurious. Continue the plants in the cool greenhouse, they could not have a more suitable situation. Placing Ericas in heat is their ruin; give them, on the contrary, all the light and air practicable. Train the shoots out by tying them with matting (but not so as to break them), to pegs in the soil. If the plants are thin of shoots, pinching out the points of these will cause the production of side-shoots, and if very bare you may cut the plants in, but a portion of young wood must be left or they may not push from the stumps. A temperature of 55° from fire heat is too warm for Pelargoniums at this season, for unless the plants are far advanced for bloom, the shoots will certainly be drawn and the flower-trusses small. 50°, with air, is quite warm enough until the trusses are formed, and 5° more is desirable to bring the plants into bloom. Keeping close to the glass, abundance of air, and no more heat than necessary to maintain the plants in slow yet free growth, are the essentials of forcing; but the less the plants are forced the finer will be the blooms. Your Arum-like plant is Richardia (*Calla*) *aethiopia*.

REPLANTING STANDARD ROSES (*K. C.*).—You may now take up the Roses that have been planted five years, and replant them after having renewed the soil, and applied a liberal dressing of manure. Defer pruning until the buds begin to swell freely, or a month or six weeks after planting, and prune rather close. November is the best time for pruning, but it may be done in spring, especially with the more tender sorts. It will cause them to bloom later.

PRUNING HYBRID PERPETUAL ROSES (*S. Williams*).—In pruning these take out the old and weak shoots, and those that cross each other, so as to form a well-shapen head. They require pruning to two eyes if the heads are as large as desired, or if increase of head be desired, to four eyes. Prune them at once.

**VINE LEAVES TURNED BROWN (One in a Fir).**—We are at a loss to account for the scorching of the leaves and fruit so early as the 14th of February. The temperature from fire heat must have been extremely high, and the air of the house excessively dry, and some other cause must have existed as well, to account for the complete destruction of the foliage and fruit. We think your border good, though we should have liked it better had it not been so deep, and without leaves over the drainage. Your pit is 4 feet deep with 1 foot of drainage at the bottom, and a good thickness of leaves above it. Leaves are apt to become a soap-like mass, and thus prevent water escaping freely by the drainage. In place of the leaves we would recommend you to place 6 inches more rubble on that already at the bottom of the pit, then a layer of turves, grass side downwards, and then to fill in with turfy loam from a sandy soil chopped with a spade, adding to this equal quantities of boiled half-inch bones and charcoal, so as to form one-sixth of the whole. Instead of mixing any manure with the compost, rely on top-dressings of rich compost for nourishing the Vines. Vegetable matter is apt to form a close heavy mass when thoroughly decomposed, and the Vine will not thrive in a soil containing an excess of close, heavy, vegetable or animal matter partially or wholly decomposed. As the roots are healthy, to what do you attribute the weakness of the wood? If you are satisfied it is due to the misfortune, and not to the border, by all means leave the latter alone. We see nothing wrong in it except its depth, the leaves over the drainage, and the manure mixed with the soil. Turf, manure, and bone dust being its ingredients, we do not see how it could be improved except as above. All the sorts are good for general purposes. Your best course would be to train a shoot from the bottom of the rod and cut back the old rod to that shoot after it had pushed another shoot a foot or so long. If cut out now the danger of bleeding is great, and the Vines will be weakened. The young cane will, if the roots are healthy, reach the top of the house this season, and if well ripened a crop of fruit may be had in the following year. We do not think any good would result from retaining the old rod and weak spurs upon it.

**VINES SHOWING FRUIT INDIFFERENTLY (A Young Gardener).**—The bunches of embryo fruit sent us were strong and long in the footstalk, the shoulders for the most part blind or defective in the flower-knobs, and the bunches inclined to curl or become tendrils. We have found such effects caused by Vines being grown in rich, deep, cold, outside borders, which have a tendency to produce gross long-jointed wood, usually imperfectly ripened. Yours, however, cannot suffer from this, the roots being in an inside border, and completely under command. You have placed a foot of manure on the inside border, and you poured cold water copiously on the manure to wash its nutritive matters into the soil. This cold-drenching a Vine-border when the Vines are but little advanced in growth is bad. A check is given every time the cold water is applied, and the rootlets form indifferently in a cold wet border. You commenced to force early—at Christmas, and the Vines were advanced for flowering by the early part of February. You brought them on slowly at first, and since they broke have kept them at 60° by night, and 70° by day from fire heat. This, combined with the drenchings of cold water, is sufficient to account for the bad condition of any Vine subjected to such treatment, especially Muscats, and these you say are the worst. Had the water used been a few degrees warmer than the mean temperature of the house, so as to bring the border into a nice moist condition, commencing to force with a temperature of 45° by night for the first fortnight, increasing it to 50° at the end of that period, in another fortnight to 55°, and in another to 60°; then we think the bunches would not have been in the condition of those sent. Throwing the house open in summer is only wise under certain circumstances, and should never be done until the wood is hard and brown, or well ripened. Keep the border moist for a short time before commencing to force, and well watered when growth commences; decrease the amount of water after the fruit changes colour, and leave it off altogether after the fruit is ripe. Bring the Vines on gradually, and do not exceed 60° by night until the leaves attain their full size. Water always with tepid water, and do not expose the Vines or throw open the house until the wood is thoroughly ripened.

**GLADIOLI GROWING IN POTS (W. B.).**—Gladioli may be so grown successfully. Pot them in six-inch pots, and transfer them to eight-inch ones as soon as the roots reach the sides of the pot, and again into a 10 or 12-inch size, plunging the pots in the open ground in March or April, protecting the foliage with an inverted flower-pot. Your soil being unsuitable need not prevent your planting them out, and as you want them for exhibiting, they do much better planted out than grown in pots. Take out the soil to a depth of 18 inches, and fill in with turfy loam, well reduced leaf mould, turfy peat or bog soil, and well rotted manure in equal parts, well mixed and chopped up, adding sand to make the compost moderately porous. This should be placed in the bed early, and 6 inches higher than the surrounding surface to allow for settling. Top-dress them, 1 inch or 1½ inch deep, in the last week in May and the second week in July, with rich compost whether they be in pots or planted out. During the growing season keep well watered, a thorough soaking once or twice a-week being preferable to constantly wetting the surface. Syringe them on the afternoons of fine days, and after a good watering stir the surface between the plants 2 or 3 inches deep, but do not disturb the roots. We do not know a creeping plant that would suit your room.

**DAHLIAS, VERBENAS, CARNATIONS, AND PICOTEES FOR EXHIBITION (W. B.).**—*Dahlias*—Bob Ridley, Lord Derby, Lord Palmerston, Cygnet, Model, Lollipop, Handforth Hero, Beauty of Hillerton, Norfolk Hero, Criterion, Caractacus, and Duchess of Wellington. *Verbenas*.—Lord Clifden, Foxhunter, Thetis, Victor Emanuel, Garibaldi, Elfrida, Chieftain, Mrs. Holford, Mrs. Moore, Mrs. Woodroffe, Urban, and Fantastic. *Carnations*.—Dreadnought, William Pitt, Capt. Thomson, Mr. Alsworth, Hope, Tenby Rival, Lucia, Christopher, Sir Henry Havelock, Mayor of Nottingham, King John, and Illuminator. *Picotees*.—Lord Elcho, Flower of the Day, Rival Purple, Favourite, Favorita, Ariel, Rev. A. Matthews, Rosy Circle, John Linton, Ada Mary, Loveliness, and Margaret.

**HORSERADISH IN PEAR-BORDER—CROPPING VINE-BORDER WITH ONIONS (G. Randall).**—You will best get rid of the Horseradish by digging or forking out the roots, persisting in this as frequently as the shoots come up. Care will be necessary not to injure the roots of the Pear trees. There is no wholesale method of destroying the Horseradish except by agents that would kill the roots of the trees as well. Onions on a Vine-border are bad, they would impoverish the soil, and so would any crop.

**MOWING MACHINES (R. M. C.).**—They all work well, and we cannot recommend one maker in preference to others. Do not have a large one if to be worked by one man.

**FOWLS' DUNG (Guernsey Blue).**—Make of it liquid manure by putting a peck to forty gallons of water. Apply the liquid once or twice a-week between the rows of drilled Onions, or to any other of your kitchen garden crops.

**BROCCOLIS FROM NOVEMBER TO FEBRUARY (M. C.).**—The Walcheren is the best autumn Broccoli, coming in in October, and lasting with protection up to Christmas. Grange's Autumn White, and Hammond's White Cape, are good useful sorts for late autumn use. Snow's Winter White is probably the only Broccoli that can be depended on (and that not always) for furnishing heads in January and February. Early White Malta is a good early kind, and Hopwood's Early White sometimes comes in in February. The seed should be sown rather thinly in the first week in April in good ground, and when the young plants are large enough they should be pricked out, finally planting in well-mannered ground, 2 feet apart, and 3 feet from row to row, taking them up with balls, and keeping them well watered until established, and afterwards in d.y weather, otherwise they will head prematurely, especially the Cape varieties. Keep them well earthed-up, and in autumn bank them quite up to the leaves with soil, mulching between the rows with litter, and a little spread over the heads in frosty nights will protect them from injury. The Walcheren should be taken up when the heads are about half their full size, and the plants laid in close together in an open shed, or where they can be covered with straw during severe frosts. We had fine, large, close heads up to Christmas last year.

**PEAS FOR SEPTEMBER AND OCTOBER (Idem).**—A sowing of British Queen made in the last week in May, will usually produce Peas for use in September. We make a sowing about the middle of May, another ten days later of British Queen, Hairs' Dwarf Mammoth, and Ne Plus Ultra, and invariably have Peas from these sowings in September and October, and we have gathered from them on the 20th of November. Sow these three kinds on ground prepared as for planting Celery, at three different times during May, beginning in the first week, and sowing at intervals of ten days, and you will have an abundant crop of late Peas of the finest flavour. If your soil is light sow early in June a breadth of an early sort, as Advancer, Early Green Marrow, and Eclipse. We make it a practice to sow these three, commencing on the 18th of June, and with three sowings at ten days interval, we have the middle of July nearly.

**VINES DISBUDDING (An Amateur).**—Wait until the shoots have grown enough to enable you to distinguish which will and which will not have a bunch of fruit, and when this is beyond doubt rub off that showing no fruit, or if both show fruit take away the smallest, giving preference to the shoot nearest the rod. You must leave one shoot to each spur, whether it show fruit or not, rubbing off all others. One bunch on a spur is ample for a good crop, more taxing the strength of the Vine too much. Stop them at the joint or leaf above the fruit, and all laterals at the first joint. The Moss is *Selaginella denticulata*, and the other *Cytisus pauciflorus*, we think, but the flower was crushed.

**PROPAGATING QUINCE STOCKS—PARADISE STOCKS (—).**—Quince stocks may be obtained by layers, and sowing the pips, now being a good time for doing both, but the earlier the better. Paradise stocks are propagated by sowing Apple pips now. *Cobana scandens* may be propagated by cuttings, layers, and seed, now being the time. Cuttings of Currants inserted now would for the most part strike.

**PLANTING CONIFERS ON MOUNDS (An Irish Lady).**—Nordmann's Silver Fir, and Picea Nordmanniana are identical. The benefit derived from planting the Pine and Fir tribe on mounds of earth is great, the chief benefit being that the roots run near the surface, and unless the collar be elevated a Conifer seldom thrives. By all means plant them on mounds with a flattened top to retain water. On good ground they do not need manure, but a little rich fresh mould placed around the roots will assist their taking hold and becoming established.

**FRUIT MANUAL (R. Coles).**—A new edition is preparing, and will be published during the approaching spring.

**REGISTRY OFFICE (A. Z.).**—We cannot answer questions which are not within our province. Consult a London Directory.

**SALTING ASPARAGUS-BEDS (A Subscriber of Many Years).**—You may apply salt now, and throughout the time of the Asparagus growing—that is, until the end of September. We have applied the salt two ways—sprinkling it on the surface once a-month at the rate of an ounce to a square yard, and dissolving it four ounces in each gallon of house sewage. This we apply once a-week. The Asparagus is a native of the sea-shore.

**GARDEN PLAN (E. A. L.).**—We purpose having your praiseworthy plan engraved and inserted with a brief comment next week.

**STEPHANOTIS FLORIBUNDA (N. S.).**—There was no fungus spawn in the sample of soil you sent. It was full of the rootlets of some plant, probably of the *Stephanotis*. The cause of its leaves shrivelling was either deficiency of temperature or deficiency of food; we think the latter was the deficiency. The sample of soil was mere fiery peat. We should remove as much of it as we could without disturbing the roots, and replace by a mixture of equal quantities of peat and leaf mould, with a little sand.

**TRADESCANTIA ZEBRINA—LAPAGERIA ROSEA (Boulah).**—The withered morsel of a specimen resembles the *Tradescantia zebрина*, or what is sometimes called *Cyanotis vittata*, a creeping, trailing plant with purplish and whitish leaves. It thrives well in a cool stove and warm greenhouse, and makes a good plant for a basket suspended in a window. The *Lapageria* likes a greenhouse not below 45°, plenty of surface room, good peat and loam, abundance of drainage, and plenty of water, but stagnant moisture is its ruin.

**ROLLERS FOR OUTSIDE SHADES (J. McI.).**—There is nothing for this purpose so light as wood. The rollers may be made from 60 and more feet in length if drawn up by each end and the middle. In such cases it is best where the pulley ropes pass underneath the roller—that is, fastened at back, come down the glass, and go back above the blind to a pulley at the top, all the ropes being joined to form one in the centre, so that one man may pull all the strings at once. A blind with a wheel or place for a rope merely at one end, should not be much more than 30 feet in length. We have seen galvanized iron rollers, stout, but hollow inside, and about 1½ inch in diameter, do very well, but if the roller is heavy, and one pulley string has too much to do, they too will warp. The best remedy is to have plenty of pulley strings, and supposing there are three, the two end ones may be brought along the top of the house to the middle, and one man can then pull all the three strings at once.

**WARDIAN CASE (C. E. S.).**—We do not know who makes these now. Mr. West has left Surbiton.

**LOPHOSPERMUM MAGNIFICUM CULTURE (—).**—Turfy sandy loam two-thirds, leaf mould one-third, with a free admixture of sand. Three plants will sooner fill a basket, but one would do better in so small a basket, stopping the shoots to make it branch. It will grow to a height of 29 feet, but is oftener seen 6 feet high. Seedlings now in the second leaf may flower this season with liberal treatment. Pot them singly in small pots; keep in a frame on a mild hotbed until the pots are filled with roots, then transfer to a greenhouse, after hardening off, and in the first week of June plant out some of them against trellises in sheltered parts of the open garden, taking out the points of the shoots when they have made six leaves beyond the seed leaves, and stopping them again at 13 inches high if they do not produce so many shoots as required. Train the shoots regularly, and this is all they require in the way of pruning. Any that are wanted to train on trellises or wires in the greenhouse, should be potted as soon after as the pots become filled with roots, or potted into a 9 or 12-inch pot at once, just as large or small plants are desired. Such plants require the same treatment as to stopping the shoots where more are wanted, or when they are inclined to become leggy. Distribute the shoots regularly, thin them if crowded, and keep near the glass.

**IPOMEA HYBRIDA MARGINATA CULTURE (—).**—Sow in a compost of light turfy loam, with about one-third of leaf mould added. Place in a hotbed frame, and when the plants are in the rough leaf harden off, and keep in a greenhouse until the last week in May, then plant them in the garden, giving them a tall stake to twine round, or, if desired, put three in a 12-inch pot, and train to the rafters of the greenhouse.

**AMARANTHUS MELANCHOLICUS CULTURE (—).**—Sow early this month, in the soil recommended for nearly all annuals—light loam and leaf mould, in the proportion of two parts of the former to one of the latter. Place in a mild hotbed, and when the plants are large enough to handle, pot them off singly in 60-pots, or three round the sides of a 48. Keep in the frame until the plants have made roots to the sides of the pots, when more air may be given, and the plants hardened off. As large plants are wanted, pot in a size larger, and grow on in the frame or a vinery at work until the middle of May; then gradually admit more air, so as to have them hardened off by the beginning of June.

**FINE FICUS PENSANO.**—In your Number of Feb. 28th "A SUBSCRIBER" speaks of a specimen of the *Ficus pensano* at Luton, being 42 feet in circumference and 14 feet high. I beg to say I have one 44 feet round and 19 feet high, very healthy and well grown.—F. W. C., *Woodlands, Red Hill.*

**BOOKS (Wigan).**—For a field naturalists' club, of "books either new or old," we recommend Smith's "English Flora," Hooker & Arnott's "British Flora," Hogg's "Vegetable Kingdom," "The Wild Flowers of Great Britain," and Seeman's "Journal of Botany." The two last-named are monthly publications.

**WALL OR PALING FOR FRUIT TREES (W. Turner).**—Build a wall by all means, having it 7 feet high, and glaze the front, as represented in our columns to-day. You may then grow Peaches, Nectarines, Apricots, and Black Hamburg Grapes in defiance of any Liverpool gales.

**CINERARIA SEEDLING (J. Call).**—A showy border flower, but will not compete, as a florists' flower, with many of the same colour.

**WALTONIAN CASE (T. A. S.).**—Mr. West, the maker, is gone, and we know of no one who now makes it. We employ the Bijou plant case, made by Mr. Stocks, cabinet maker, &c., Archer Street, Notting Hill, London.

**DWARF ROSES IN A BED (Eesham).**—We have no doubt that Général Jacqueminot will make a very good bed, and the plants may either be pegged down or allowed to grow bush fashion. If the latter, cut out the most robust and coarse shoots as they are produced, and the bed may be made to assume a tolerably even appearance. We have this and other Roses, grown on their own roots, in beds, and prefer such plants to those on Manetti stocks, when the kinds will succeed in this way. Baronne Prevost, Général Jacqueminot, Jules Margottin, and others do remarkably well.

**OAK TREES NOT THRIVING (A Constant Subscriber).**—We fear there is something radically wrong with your Oak trees, which you say are growing in a field on a dry clayey bottom, so very dry that, after a dry season, the soil is so dry and hard that it is late in autumn before it becomes wetted through. If the trees are not very old they might be benefited by the surface being partially removed, and light soil, containing more sand or gravel in its texture, substituted for it. We hardly recommend watering, as nature generally supplies moisture enough for all kinds of trees, excepting those newly planted, which yours are not.

**APPLE TREES NOT PROSPERING (J. C.).**—There must be something the matter with the roots, or your trees, planted three years, ought to have grown some considerable size ere this. We hardly know how to advise you, in the absence of more information about the situation and kind of soil. Ribston Pippins are not by any means the best thriving of Apples, but Nonsuch ought to do well. Cutting back will not affect their general health much, and will not certainly improve their stunted growth, which either arises from the soil or climate, or perhaps both. Write again, stating your locality, and other particulars.

**NAMES OF INDIAN AZALEAS (June).**—The colour was too faded before we saw the blooms to give us a chance of identifying them; but had they been fresh the varieties are too numerous to justify naming without seeing the plants.

**NAMES OF PLANTS (M. C.).**—1, *Asplenium bulbiferum*; 2, *Asplenium flaccidum*—two species which are closely connected by intermediate forms. 3, *Pteris longifolia*. (D. E.).—1, *Asplenium cicutarium*; 2, *Blechnum occidentale*; 3, *Pteris tremula*. (John Bryan).—1, *Onychium lucidum*; 2, *Adiantum capillus-Veneris*. The insect is the common Mite (*Acarus*), and it feeds only on decayed vegetables. (B. C.).—It is *Lycopodium clavatum*, or Club Moss, sometimes called Wolf's Claw. It belongs to the Natural Order *Cryptogamia Lycopodiaceæ*. (C. P.).—Your Mosses are—1 and 3, *Hypnum rutabulum*; 2, *Hypnum complanatum*, and, mixed with it, *H. curvatum*; 4, *Hypnum prælongum* and *H. denticulatum*; 5, *Bryum ligulatum*; 6, *Polytrichum undulatum*; 7, *Bryum hornum* or *B. stellare*; 8, *Tortula subulata*; 9, this has no fruit, but it is either *Dicranum bryoides* or *D. taxifolium*, probably the latter; 10, *Jungermannia asplenioides* var. minor, mixed with *Hypnum trichomanoides*.

METEOROLOGICAL OBSERVATIONS in the suburbs of London for the week ending March 4th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.

This subject is one of real importance, and should be fairly and good-humouredly discussed. The promoter should be prepared to answer every reasonable objection, and "C. S. J." has stated nothing unreasonable. I never heard of the profit of a large number of hens averaging more than 5s. per annum per hen, and surely it is most ample, considering the commercial value of the animal to be about 2s. 6d. When you come to reckon your hens by thousands, if you get from each 120 eggs in a year you will have no cause to complain. Their wholesale value in summer I cannot determine, though I have never bought a new-laid egg in London for less than 1½d.; but we all know that retailers look for enormous profits, so I incline to the opinion of "C. S. J.," that 5s. per 100 would be about the summer wholesale price. As to the value of chickens at six months old, it depends on the season, supply, demand, and quality;

but I cannot conceive how a bird is to be fed and made so fat at such an age for 9d.

If Mr. Geyelin wants to form a company to carry out such an undertaking he should show how it is to be done. His unsupported statement is fairly liable to be questioned, but facts and figures carry conviction. A mere Dr. and Cr. calculation on paper will not do, we must be governed by the markets. It is my own opinion that, taken as a whole, the profits estimated by "C. S. J." are considerably above what would be realised in practice, yet he allows only £2153: whereas Mr. Geyelin's nett profit is £7326, both on a capital of £3000. To be really safe all such calculations should be based on a *minimum*, while I fear Mr. Geyelin has taken a *maximum* scale. Some minds are naturally very sanguine, and can view things only in a favourable light. This may lead to great mental happiness, but monetary disturbance. It may be very fairly questioned if such an undertaking could be properly managed by a company, for its success must entirely depend on individual energy and attention. To earn a dividend for the shareholders the directors should do as the higglers do in Sussex—they should devote all their time to the business. I incline to think a partnership, where all the partners would divide the work fairly between them—

selves, would produce a far better result than leaving everything to paid servants, whose first care is ordinarily for themselves.

I know not how it is, but artificial incubation does not seem to be permanently successful amongst us. Cantelo's system made a prodigious noise for a time, but who ever hears of it now? His "Hydro-incubator" was exhibited in every stage of operation at a charge of 1s. He then established a small "Poultry Farm" at Chiswick, but after all he could do no good with it. Now with every kind feeling for Mr. Geyelin, and with the heartiest wishes that the utmost success may attend his speculation, what proof, I would ask, have we that his system of artificial incubation is in any respect superior, commercially, to that of Mr. Cantelo? It is obvious the success of the Company must entirely depend on the perfect success of his incubator; and I need not say to establish the success of anything now-a-days is a work of time, trial, patience, politeness, and perseverance.

An inventor must bear in mind that to object is not to condemn. An inventor must be prepared for severe criticism, and so long as this is fair and reasonable so much the better for the inventor, if his invention safely passes the scrutiny. This is the royal road to popular favour, which makes his fortune.—NEMO.

My estimate of revenue and expenses is based on facts ascertained by actual experiments, and I maintain its correctness. If your correspondent, "C. S. J.," previous to proclaiming himself the public Mentor, had favoured your readers with the results of his own experiments in lieu of publishing surmises based exclusively on his personal opinion, they would, no doubt, have been received with all due deference.

My system of feeding chickens is far cheaper than the present mode, and is calculated to develop the size and bones in the shortest space of time, and not flesh and fat, which can soon be done when the frame is ready to receive it.

The market commission is 5 per cent. on dead stock, and not 10 per cent., and a chicken six months old fattened with barley and Indian-meal is more likely to fetch 3s. 6d. than 2s. 6d. The expenses of one home being divided among six hens and one cock are necessarily heavier per head than when divided among twelve or eighteen laying hens, or from twenty-four to thirty chickens. The choice birds, I am informed by many, ought to produce over £1000 from among 50,000 chickens per annum.

I am pleased to perceive the interest "C. S. J." takes in this subject, and I trust that the Company now forming will have the advantage of his co-operation, with a view to solve the problem "OSTEND RABBIT" so forcibly puts in his masterly letter. Is there any valid reason why England should not supply her own wants in the shape of eggs, poultry, and rabbits?—GEO. K. GEYELIN, C.E.

#### HOME SUPPLY OF POULTRY AND EGGS.

How long does it take for a question to go through all its phases, to settle down as a recognised fact before the public, with the certainty that it will only be disturbed now and then, at stated periods, to be ventilated according to some, or to have the accumulated dust of years rubbed off according to others? Fourteen years ago, the public one day recognised the fact, that poultry was a pursuit, that it was deserving of encouragement, and then some thought it was a mania. The pursuit of the trade of a "poulter" is not one of yesterday. Its Guild, or Company, ranks among the ancient ones of the City of London. It has in its day lent money to the Sovereign of the United Kingdom. It still exists, and has its chartered rights; and its bequests and benefactions go back to the sixteenth century. It seems now as if its claim to a share in providing food for the vast populations in the metropolis and large towns were about to be properly considered. We are no longer self-supporting in the way of food. Many of us can recollect in one of the old Anti-Gallican songs, it was said—

"They want to get our flesh and blood,  
Our beef and beer."

Things are altered—we get a good quantity of theirs;

and half the continent is laid under contribution to supply our carnivorous propensities. Good sound men of figures prove that the supply of food decreases, others point to an increasing population, and the increasing price of meat. The leading journal of the world but lately called attention to the figures of our imports in the way of food, and was obliged to pause at one item. "A million of eggs imported for every working day in the year;" Turkeys by thousands; Rabbits by the ton. These are helps to the food necessary to feed the metropolitan millions; but the question naturally suggests itself, Do we do all in our power to provide more of these things at home?

The egg trade with Scotland is becoming a very large one. We import eggs from France, Holland, Belgium, Switzerland, and part of Italy. Cannot we do something towards providing ourselves with these valuable luxuries, and thereby not only increase the number, but probably decrease the price of them? We have in our favour, and, consequently, to our profit, all the expense of foreign agents, of travelling, freight, carriage, and dues. With eggs produced at home nearly all this would be avoided. If those who can keep poultry will not keep them, then those who have the inclination without the convenience, must endeavour by association to find the means of carrying out their theories and ideas on the subject.

We believe we are correct in stating, that plans are now a-foot, which will in all probability result in calling public attention to the subject, and in giving the question a fair trial on a large scale.

#### THE POULTRY CLUB.

Your correspondent "A TIMID EXHIBITOR" says, in his first letter, that one of the main objects for which the Poultry Club has been formed is the discouragement of dealers as judges at any show. Even if the Club have acted up to this rule, they have fallen into a worse error than if they had completely ignored it—viz., they have left the appointment of judges in the hands of dealers, who are also amongst the largest exhibitors, and whose interest it is to win prizes, not merely for the sake of the prize itself, but as a means of raising the value of the birds they have for sale.

In my opinion any person is a dealer who breeds or purchases poultry, and afterwards disposes of it for a pecuniary consideration. There may be two kinds—the amateur dealer who, whilst he keeps poultry for amusement, endeavours by selling birds at a profit to make the receipts cover the expenditure. Amongst this class I should place several of the Club's stewards, and also some of the persons mentioned by Mr. Boyle. The other class of dealers make it part of their trade to buy and sell poultry, as for instance Messrs. Baily, Yardley, Hutton, Beldon, &c. I do not say that all the Club's stewards are dealers, but there are a few whom I can point out who deal in fancy poultry to a large extent. Their influence with the judges appointed by themselves must obviously be great. This circumstance no doubt accounts in some degree for a fact that must have been noticed by many of your readers—viz., birds purchased of this class of people generally leave their winning properties behind them, although remarkably successful when exhibited by the dealer.

I have been surprised in looking over the prize-lists of recent shows to see how very successful these gentlemen have been lately. One of them, an extensive dealer, according to his own advertisement has taken 537 prizes, including eleven silver cups, since January, 1864. I am not the only person who has made remarks about the success which appears to cling to members of the Club when their own judges are officiating.

Mr. Ranwell in his letter about the Islington Show remarks "that he thinks the rules of the Club have been compiled by the members solely with an idea of pleasing their own fancies." If such were not the case he thinks the prizes would not have been so thickly distributed amongst the members as they were.

I advise "A TIMID EXHIBITOR" not to join the Club until some alteration is made in the management; and then it would be better if the Club would confine itself to simply

giving its opinion on the different qualifications which constitute a prize pen, and leave exhibitors and judges to choose whether they will follow its advice or no, and not to wish to appoint judges for every show, but leave that to the committees, who are much better able to do so.

I admire the way in which the Hon. Sec. endeavours to prevent any public discussion on the management. Still I should have thought that, as the promoters desire that the Club stand or fall on its own merits, they would be only too willing to discuss them if it had any merits to stand on. Is it because it has none that the Stewards are afraid? Certainly one of the principal objects is a failure. Perhaps all the others are the same.

In conclusion, I think it would be better to have dealers that are not exhibitors as judges than to allow dealers who are exhibitors to choose them, for certainly the dealers who exhibit have the most interest in who gets the prizes. If the present system of judging is continued I venture to predict that it will soon disgust all honest exhibitors with the pursuit, and thus prove a check on a very entertaining and useful fancy, as it has already done to one who has ceased to exhibit, and become merely—A LOOKER-ON.

HAVING noticed the letter of "A TIMID EXHIBITOR" in your Journal of the 21st ult., inquiring "who claimed the first-prize pen of Game Bantams at the late Manchester Show, and resold them there?" I beg to inform him that the pen was claimed on the suggestion of Mr. Douglas, but not before the opening of the Show and the admission of the public; in fact, several other pens were claimed before it; also that Mr. Douglas had nothing whatever to do with the resale of the pen.

If we take your correspondent's definition of a dealer, I fear we all come under that class. He wishes to prove Mr. Douglas a dealer, because some two years ago upon the Hon. W. W. Vernon's relinquishing exhibiting, he sold that gentleman's stock of poultry, and has since adjudicated upon some of it; but with what result the instance named in "A TIMID EXHIBITOR'S" first effusion only proved Mr. Douglas's integrity as a judge, for upon the occasion alluded to (Leeds), though several birds formerly the property of Mr. Vernon were competing, not one obtained even a commendation. I would strongly advise your correspondent to write openly, and attach his name to any charge he has to make against any one; but I fear had he done so in this instance, he would not have been found the timid exhibitor he professes to be.—HE THAT RE-SOLD THE MANCHESTER FIRST-PRIZE PEN OF GAME BANTAMS.

I AM an amateur poultry-breeder, and I suppose that I ought to be called a *dealer*, because during the past year I have received £40 by the sale of birds and eggs. This is an admission some persons might not be willing to make. In that pleasant book, "Our Farm of Four Acres," is the following—"Our fruit was as plentiful as our vegetables; indeed, we might have sold the surplus for some pounds; but we soon found that to do so was to lose caste in the neighbourhood." Oh, cold shade of shabby gentility! perhaps this may be the case in mine. I neither know nor care. My fresh butter is sometimes stamped with the name of a baronet, and at others with that of a wealthy squire. I neither like them nor their butter the less for it. Until the beginning of last year I did not make any attempt at sales; in fact, up to that time I had very few birds, and had only twice exhibited. Hear this, ye "timid exhibitors," and those whose groans about unprofitable poultry, and the unfairness of shows, have from time to time appeared in these pages.

From certain circumstances which occurred, I was at one time disposed to look unfavourably on the Poultry Club, although I advocated the principle of the association. I have since seen reasons which have induced me to become a member. Two things, however, have not pleased me since I was elected. The first was that sweeping condemnation of the judging at Birmingham last year, where I exhibited, but was not successful. The second is the offensive prominence given by the Club to the fact, that dealers are to be excluded from public judging at the shows.

I should not be at all afraid to trust myself in the hands of more than one dealer that I know, whether he acted as

a salesman or a judge; but at the same time I can see good reasons why dealers should be excluded.

Except that an ugly imputation seems to be implied, I think that few dealers can object to the principle of judging laid down by the Poultry Club; but if the rule exists, and I am not inclined to oppose it, the matter should be fairly carried out, and all persons should be excluded from public judging who are either dealers by occupation, or who, as amateurs, directly or indirectly sell poultry.

In cases of dishonesty, I am afraid that exhibitors are frequently as much to blame as judges, and in dealing I do not think one is by any means safe in the hands of amateurs, who frequently disappoint by ignorance as well as by design.

There is a suggestion in a contemporary, which is worthy of repetition, and which would meet the difficulty of judging half way. It is proposed there that the Poultry Club should adopt the plan followed at Manchester, where the pens are numbered in the judge's book according to their order of entry, and not according to the position of the various classes in the catalogue, so that no communication of numbers can take place between exhibitors and judges.

Judges should in all cases be provided with books that have neither the names of the owners of the birds nor the numbers in the catalogue. The preparation of these in manuscript would be simple and inexpensive. As I dislike anonymous communications, I will give my name, which, however, will be scarcely known, as I have seldom exhibited, and as I have conducted my dealings in the first instance in the name of my man.—GEORGE MANNING, *Member of the Poultry Club.*

#### MORE CLASSES AT POULTRY SHOWS.

At this season, there is by common consent a lull in the poultry world. Shows are over, secretaries are resting after their labours, prize birds are attending to their domestic duties, nursing, perhaps, the infants whose full-grown proportions will, next winter, be the admiration of Belle Vue, and Bingley Hall. This, then, is the time for managers to review the past, and deduce useful hints for the construction of future schedules. Now, too, is the time for a humble exhibitor to express wishes and feelings which he believes are in unison with those of others. Not long ago, a worthy beneficed clergyman was asked, "What are the great wants of our day?" His reply was a ready one, "Cooks and curates." Possibly he was suffering from the effects of a half-boiled Potato, or an ill-cooked chop. Perhaps he felt "Monday-ish" after a Sunday of overwork. Be that as it may, we, too, have an answer to the question. "What is the great want of poultry exhibitors." In a word, "More classes."

I need hardly explain why this is. At all but the leading shows the classes are so few that several varieties compete together, one of these often sweeps off the prizes *en masse*, and the other varieties are ignored.

Exhibitors will know the unsatisfactory feelings that arise from finding their birds beaten by another breed or variety. To see your noble White Cochins, over whose snow-white plumage and fine proportions you have chuckled many a time, "hiding his diminished head" from the victorious Buffs; to find your Light Brahma with his spreading black cock's tail thrown into strong relief by his white body, and with fluffy thighs bulging out like a Dutchman's inexpressibles; yes, to find even such charms as these unavailing against his dark rivals; to discover, alas, too late, that White Dorkings have little chance against the coloured birds—surely this is enough to sour the milk of human kindness in the breast of the exhibitor, and, then, as a result, what happens? He goes home, "a sadder and a wiser man," and his conclusion may be embodied in the remark of a certain Game breeder. "I am not such a fool as to send my Duckwing cock to ——. There is only one Game class, and the Reds will take the prizes." Let me then call upon managers to give us *more* classes, even if the prize money in each class is reduced. Let the cake be cut into more, though smaller slices, and then fewer will be sent empty away; for, after all, it is not the value of the prize, but the honour of it, which we exhibitors are seeking.

In conclusion, let me apply to poultry prizes the same wise policy suggested, I think, in the "Rejected Addresses," in

the preface to which it is pointed out that the difficulty and unpopularity of giving a prize for a poem, arises from the fact, that each poet has at least six friends, all of whom think his the best of all possible poems, and that no prudent man will encounter such a host of enemies. Let our Show Committees multiply their classes, and the number of discontented folk will be lessened in proportion. I cannot but hope that the "wise Persian," and our kindly friend, if I may call him so, the "WILTSHIRE RECTOR," will add their weighty approval to the humble suggestion of—**BRAHMA FOOTRA.**

P.S.—Since writing the above I have read with much pleasure the letter of "Y.B.A.Z." in your last issue; it is not the first occasion upon which I have been fortunate enough to agree with his views upon poultry matters; and in every one of his suggestions last week I most cordially concur.

### THE "WILTSHIRE RECTOR" AND FANTAIL PIGEONS.

A GREAT statesman and an almost equally great author, is said, some years since, to have met with an accident in a remote part of the kingdom while travelling. He was supposed to be grievously injured—report said he was killed; he was aware of this report, and was in no haste to contradict it, but quietly waited for what he knew would follow—the history of his life and comments on his character in the newspapers. Sure enough out came the many-columned biographies, out came the leaders thereon; and he read them, and so was able to gather what his contemporaries thought of him they supposed to be dead: indeed, he had the double advantage of life and death. Now, the "WILTSHIRE RECTOR" had no need to meet with an accident, no need for a report of his death—his bones were unbroken, his flesh unbruised; but still for all that he, in THE JOURNAL OF HORTICULTURE of February 21, had the pleasure to read an account of himself, nothing sad having happened, written by "B." Ah! who is "B.?" What is he like, this busy "B.?" What is he like? Where lives he? He knows one Wiltshire clergyman, that's certain. Perhaps he lives in Wilts, or wanders hovering from county to county. I will tell "B." that the breakfast at Hilltop Rectory was even more than usually hilarious when his description of "WILTSHIRE RECTOR" was read on that Wednesday morning. Well, the description of the "WILTSHIRE RECTOR" is partly right and partly wrong. I speak only of his outer man; of the rest I am not the proper person to speak. There are many much better men and some worse men, I fear, in the world than "WILTSHIRE RECTOR." I will not say in what respects the description of face, figure, and feature is incorrect, or I may this spring be met in the Strand by "B." or his friend, and be recognised. This much I will say, that the "WILTSHIRE RECTOR" is very pleased to make friends either in person or on paper. This is too cold a world to refuse one the very least bit of kindness. I went to see good "Y. B. A. Z.;" and I shall be happy to visit any other good poultry-yard or Pigeon-loft if not too far off. Already I number several pleasant acquaintances made through the Journal.

But I have something else to write about besides "WILTSHIRE RECTOR." I have long held an opinion, strengthened by recent inspections, about Fantail Pigeons, concerning which I should like the judgment of any other Pigeon-fancier, especially that of Mr. Brent. First I would say, I am anxious that we should in all cases decide if possible as to what are or are not pure and distinct races. The Barb is evidently one, and a very beautiful one. The Carrier is another, but not so the Horseman and Dragoon. The White Fantail is, I think, a pure race, and the only pure Fantail; all coloured ones I believe to arise from crosses, more or less remote, with the Runt. My reasons are these: The difference in the eye principally, in the head partially. The White Fantail's eye is very peculiar. Says Delamer, "The iris of the Fantail is of a deep hazel; the pupil black, which gives to the eye a fulness of expression quite different to what is seen in most other birds. Col. Sykes, in the 'Transactions of the Zoological Society,' makes the colour of the iris an important guide in determining the affinities or dissimilarities of species, believing it to manifest occasionally

even generic distinctions." Now, the eye in the coloured Fantails I have seen is very different—sometimes gravel, at other times orange, and not set in the head in the same somewhat pig-eyed way. Again: I think the coloured Fantail is crossed with the Runt rather than any other Pigeon, because the Runt has the throat-tremble, "the shake," and some of them carry their tails much turned up; also coloured Fantails are of Runtish colour and shape, and have usually less ample tails—that is, in the specimens I have seen, and are larger, much of the delicacy of the neck being gone with the snake-like form of the head. I invite the opinions of experienced fanciers on this subject.—**WILTSHIRE RECTOR.**

### KEEPING EGGS FOR HATCHING.

"W. M." suspends a large wooden tray half filled with bran to the kitchen ceiling, about 3 yards from the fire. The eggs are half covered with the bran, and small end downwards. There is a pretty good current of air to the eggs frequently, and the situation is dry and warm.

[There is no objection to your plan, except that the eggs may be too warm; but half the trouble might be saved. As there is now no fear of frost the eggs are perfectly safe in any outhouse, and in any box or basket, and there is no danger of their failing to hatch.]

### PARROT MANAGEMENT.

ELEVEN years ago I bought at my door a poor shabby Parrot, dying of cold, influenza, and cholera. I cured him with chicken broth, vermicelli, and mace in it, of which he drank greedily, and weak tea, with sugar and milk of course. Next day he was all but well. He is a splendid specimen of the King Parrot of Buenos Ayres, and has travelled half over Europe with me. He has never been ill but once, from extreme cold at Thun, where I could have no fire for him last summer. His food is regular—tea and sop, with a little bread and butter on the top, morning and afternoon, always fresh and warm, sugar and milk of course. At one o'clock he has any baked pudding that may be going (rice, or bread), or light dumplings, which he likes, and now and then some fried fish, which all Brazilian Parrots, I have learnt, are fond of. The staple of his diet consists of berries of the common thorn, which I have collected by bushels for his winter consumption. These yield to walnuts, and these to young larch and fir cones. No Parrot can be healthy without plenty of wood—bits of oak, elm, hazle, beech, Spanish chestnut, larch, and cherry. Black currant is an especial treat when the buds are springing. The wood is especially necessary both as food and for digestion; and a Parrot is called mischievous for nibbling chairs by those who do not understand this. Plenty of tepid water to drink, and gravel stones sometimes, are also necessary. My bird has the warmest place by the fire; but no bird should be, as I have seen them, pitilessly exposed in a cage, without power of relief or escape, to a blazing fire, or to sun, cold or rain on a balcony. They cannot endure the glare in their eyes. They should be very warmly wrapped up at night. Mine has many folds of serge and baize round him, and he only inhabits his cage at night. By day he can stretch his legs and walk where he likes, sometimes flying in my room. These affectionate creatures deserve better treatment than they often receive. I have also two very handsome Dominican Cardinals, and during seven years they have never been ill. With these the grand secret is to give them plenty of fresh water daily, seeds, both canary and hemp, and a piece of fresh turf at least twice a-week. They will extract every insect diligently, and it amuses and prevents them picking their legs, as they are apt to do if neglected. When turf cannot be had they should have cold beef or mutton very finely minced, cooked meat, or hard-boiled egg, once or twice a-week. As they generally die within a year in confinement, I mention these facts, which I had from the gentleman who kindly brought the birds for me from Brazil.—**OENITHOLOGIST.**

P.S.—Tardy moulting in birds is like difficult teething with children, and requires relief. A Parrot often suffering from inability to shell the feathers on the back of his neck where the bill or claw cannot reach, these should be very gently shelled between the finger and thumb; while playing

with the bird it is easily done, and he experiences immense relief, for these spurious processes are very painful, but the greatest care and tenderness must be adopted, as the quills are very evidently tender and painful to the touch, and irritate the adjacent skin; so of the cheeks and breast, which I shall always, and below the beak.

### REMOVING OLD COMBS.

WHICH is the best and simplest way of taking out the combs, which are four years old and quite black, from one of Taylor's amateur's hives? Shall I take the old black empty combs out and leave the new ones in, and how shall I get the bees out, and where drive them to while I take out the combs? I should much like to know if Mr. Lowe dare make such experiments with common straw hives, and if he does not protect himself in some way against their sting. He states in his last chapter that he has great faith in operating on their fears. I should very much like to know when bees are in that state, for they often put me into it?—A YOUNG BEE-KEEPER.

[The usual mode of operating on the fears of bees in common hives, is by what is called "driving," and this was, we believe, what Mr. Lowe refers to in page 123. You will find a full description of the process from the pen of Mr. Woodbury, in p. 423 of our fifth volume. In your case, however, having to deal with a bar-hive, driving is not necessary, and a different system of tactics should be resorted to, selecting the middle of a fine day for the operation. You will require a bee-dress and stout gloves, a strong spatula or palette-knife, a bent knife, some sweetened water, an empty beehive, and a lighted fumigator or cigar, or some smouldering rags firmly rolled together. Having withdrawn the screws which secure the crown-board, and donned both bee-dress and gloves, pass the spatula under it all round until it becomes loosened, then slightly raise it at the back, and blow under it two or three good whiffs of smoke, after which it should remain closed a minute or two whilst the bees are filling themselves with honey. Next, lift it boldly off, and stand it safely on one side so as not to crush any bees which may adhere to it, and liberally sprinkle the interstices between the exposed bars with sweetened water. Should the bees take this in good part without commencing an attack, the operation may be at once proceeded with; but if their pugnacity be not quite subdued, a second subsidy of sweets should be accorded them, and the crown-board replaced for a few minutes to give time for their acceptance of the proffered bribe. All these manipulations are based upon the fact, that when bees are alarmed they immediately fill themselves with honey, or such other sweets as may be at hand, and that if we can induce them to do this they become as inoffensive as house flies. No provocation short of absolute crushing will induce them to sting. Having proceeded thus far, the next step will be to sever the end attachments of one of the side-combs, which must then be lifted out and stood in the empty box placed ready to receive it. Loosen the next comb in like manner, and having examined it put it in the place in the hive previously occupied by the side-comb. Continue this process until you have examined and shifted every comb, and made up your mind which two (if any), it will be desirable to remove. There will be little brood at this season, and none of it must be sacrificed, neither should the stock be deprived of more than two combs. Having selected these, the bees should be brushed off them into the hive with a feather, and the combs at once conveyed in-doors. The remaining combs must be brought together so as to leave the vacancy on one side, and the crown-board replaced. If there are more worn-out combs to be got rid of, the operation may be repeated next spring.

We have given the information you require, but with combs only four years old we doubt the necessity or even the expediency of removing any of them.]

### RE-USING THE COMBS IN DESERTED HIVES.

I HAVE a nine-frame-hive that was deserted by its tenants last autumn, the runaways leaving the frames filled with comb containing much of bee-bread and some sealed honey. The box being left for some time without inspection, I now find

that all the combs are more or less mildewed, and the bee-bread, where not covered with mildew, has a moist watery appearance as though from fermentation. Would there be any danger attending the use of the combs? Is there any means of cleansing them? or if used would the process of cleansing by the bees themselves be more troublesome to them than profitable to—L. G.?

[If there be no foul brood in your deserted combs they may very probably still be made useful. Remove immediately as much of the mildew as possible by brushing their surfaces lightly with a soft brush, pick out any dead bees there may be in the cells, and then put the whole carefully away in a dry place out of the reach of mice, moths, or other vermin, until wanted for use.]

### OBTAINING THE MOST HONEY.

I HAVE five stocks of bees—two in Woodbury frame hives, two in straw skeps, and one in an old-fashioned box.

The two in the Woodbury hives and one in a straw skep, having a flat top and a super to fit, are swarms of last year, the other two are older. As far as I can see there are plenty of bees having large stocks of honey in each.

Now, I want all the honey I can possibly obtain this season. Will you kindly advise me how to proceed to attain that end?

I tried putting small boxes on the top last season, but failed as they were always filled with brood.—NOVICE.

[You cannot do better than put the usual sized supers on your Woodbury hives. These will hold about 25 lbs. each, and, if rapidly filled before the honey season be over, may either be removed and others substituted or raised on square wooden frames or boxes, without either top or bottom, from 3 to 5 inches deep, and of the same diameter as the supers. Side communication is preferable, as tending to prevent the queen ascending and breeding in supers. Full-sized supers should also be put upon such of the straw hives as will admit of it, and the others may be permitted to swarm. When the honey harvest is over the bees of the surplus stocks or swarms should be expelled by driving, and united to those intended to stand the winter.]

### THE REV. W. C. COTTON AGAIN AMONGST US.

Most old apiarians will remember the interest excited some three-and-twenty years ago by the appearance of "My Bee-book," by the Rev. William Charles Cotton, M.A., student of Christ Church, Oxon, and there are probably few among us either old or young that have not at some time sought with eagerness the opportunity of perusing it and thoroughly enjoying the genial style in which it is written, as well of admiring the profuseness and beauty of its illustrations. Long has he been absent from among us, and long have I and many others mourned for him as for one dead. I feel sure, therefore, that the breasts of hundreds will feel the same thrill of pleasure which pervaded my own on first hearing that he is not only yet alive and again amongst us, but that he takes much interest in what is going on in the apiarian world, and is desirous of initiating some experiments connected with his old pursuit. That the genial pen which has so long lain dormant may again be roused to activity, and that this ripe scholar and accomplished gentleman may long be spared to investigate the hidden mysteries of apiarian science is the fervent prayer of—A DEVONSHIRE BEE-KEEPER.

### TAKING HONEY IN ASSAM.

LIEUT. COCK, 43rd Regt., N.I., writing in a recent Number of our sporting contemporary *The Field*, thus describes the native mode of taking honey from wild bees in Assam:—"On the 18th April, the Garrows\* soon joined me, and told me they had marked a bees' nest, and would take it if I liked. Thinking a little honey would be nice, I said I would come with them. A naked Garrow now stepped

\* The Garrows are a fine athletic race of savages, who go naked and live in the hills.

out and unslung the basket he carried on his shoulder, took the contents out, and put in some fresh green leaves. He then collected some eight or ten stems of a dried reed, and tied them together with a cane; round these he bound a lot of green leaves and a hooked stick, so that the hook projected beyond the faggot or torch. All was now ready, so I followed him to a tree, where, high up on a bough, was a bees' nest. It was about a yard in diameter, and hung suspended to the underside of the bough, like a great black cheese. The Garrow having lit his torch, swung up the tree like a monkey, hung his torch by the hook to a bough above the nest, with the lighted end hanging down under the nest, so that the smoke thoroughly cleared each side of the comb. This done, after waiting a few seconds, he cut off the comb, put it in his basket, and descended. He was only stung over the eye in one place."

#### EARLY APPEARANCE OF DRONES.

In my apiary of fifteen hives, one, a square box with a southern aspect, has already bred numerous drones, which to-day (Feb. 20th), although the ground is covered with snow, are flying around in great numbers. Apparently one quarter of the population of the hive consists of drones. I have kept bees for many years, but have never observed drones at an earlier period than the middle of March, and there is an old saying that "You may count upon a swarm three weeks after the appearance of the first drone."

This hive is heavy, and strong in bees. Can any of your experienced correspondents explain this phenomenon?

May I also ask for advice with regard to placing a swarm in a unicombe hive, and also in the Stewarton hive? A single box of the latter being only 4 inches deep would appear to me to cause a difficulty. Is it possible to obtain well-made Stewarton hives in the neighbourhood of London, and the price?

I may here mention a curious fact which occurred in one of my hives in the winter of 1863:—

On the 28th of June of that year I had a swarm, which was hived and placed in a retired part of my garden; in the following September its weight was 24 lbs. During the month of December this hive was overturned by a mischievous boy swinging near the spot. It lay bottom upwards for three weeks, snow having fallen, and several severe frosty nights having occurred meanwhile, before discovered, this mischievous imp not daring to proclaim his own delinquency. To my astonishment the bees were alive and flourishing. The hive was replaced upon its stand, continued to do well, and threw off a good swarm early in the following June.—GEORGE RAYNOR, *Kelvedon Hatch Rectory, Brentwood.*

[There is little doubt that the queen of your colony in a square box is a drone-breeder, but in the absence of all information with regard to the history of the colony we cannot explain how she has become so. She should be at once destroyed, and her subjects united to the nearest stock. If the box be furnished with bars her capture may readily be effected by lifting out and examining the combs. If destitute of this essential convenience, the bees should be expelled by driving, and must then be looked over until the queen be secured. Should you be unable to perform this operation the entire colony had better be destroyed by means of sulphur, and the remaining honey appropriated to your own use; or, if the combs be new and in good condition, the whole may be carefully preserved until the swarming season, when it will prove of inestimable advantage to a young colony.

Stocking an ordinary unicombe hive is generally a very troublesome affair, but by adopting moveable bars the process becomes an easy one. There is little difficulty in furnishing any unicombe hive with moveable bars three-quarters of an inch wide by three-eighths thick. These should be ranged side by side in a box fitted to receive them, and at such distance apart as to be an inch and a-half from centre to centre of each bar. Guide-combs having been attached, the bees should be hived in the first instance, and allowed to work in this box, which must occupy the position destined for the unicombe. In three or four days the combs will have made such progress that during the middle of a

fine day they, with the bees, may be at once transferred to the unicombe hive. By means of this arrangement the colony may also be preserved alive through the winter if, as autumn advances, they are replaced in their original domicile.

A Stewarton hive should be stocked by having a swarm in the two lower boxes united and communicating with each other. These hives are manufactured so well and so cheaply in Scotland that no London workman can afford to make them at the price; nor are they, so far as we know, to be obtained in the neighbourhood of the metropolis.]

#### CRUMBLED COMBS—DYSENTERY.

I RECEIVED recently from Germany a hive of bees in a straw hive. They were very lively after so long a confinement. The next day being very wet very few bees left the hive that day; but the day following was very fine; yet as only a few left the hive, I became uneasy, especially on perceiving they showed signs of relaxation on the floor-board.

On turning the hive up, I found numbers dead, with much comb crumbled, and, I believe, with little or no honey in the combs. I immediately gave them some food in a plate, but as I am from home while writing the above I cannot state the result as to their taking it.

I wish to know in respect to the fæces which, I have not the slightest doubt, from the colour and liquid state, indicate incipient dysentery, what food to give them, and how otherwise treat them.—T. S.

[The crumbled comb is owing either to the bees gnawing off the cell covers, or to the presence of the wax moth, which is a far more formidable enemy of bees on the continent than in this country. Fine mild weather is, we believe, the only effectual cure for dysentery, but feeding is often beneficial, and for this purpose we should prefer pure honey liquified by the addition of a little warm water, or even lump sugar and water only, to the mixture of moist sugar, ale, and honey. We have no faith whatever in any of the various nostrums recommended in bee-books as cures for dysentery.]

#### OUR LETTER BOX.

**BEST AGE OF BREEDING FOWLS** (*Abraham Dawson*).—A cock two or more years old, and a hen one year old, usually breed the best chickens. It is uncertain how long the fertilising influence lasts. It is certain one intercourse is sufficient for all the eggs laid by a Turkey hen in one season.

**LICE ON CHICKENS** (*Nelly*).—The result, in your case, is that which generally occurs when chickens are reared in a room. Nothing is so productive of parasites. They lack air, the scratch, and the numberless little essentials they find when at liberty. The train oil kills the vermin, but when they are very young it often kills the chickens also. In such cases it is almost as fatal as the vermin. We advise you to do away with your nursery, and to bring the chickens down stairs. Put the hen under a rug, in a sheltered spot, free from draught. Cover her up securely at night; choose the position so that if there be any sun the broods can have the advantage of it. Chickens seldom do well on boards, let them be covered ever so thickly, and hardly ever in doors.

**WHOLESALE PRICE OF EGGS**.—I have read lately with some astonishment the prices made of new-laid eggs by a writer in your Journal. I have between eight and ten thousand eggs yearly from fowls kept by myself in a farmyard, and I find the average price I make of them is 6s. 2d. per hundred. They are sent to the shop generally every third day. If you, Messrs. Editors, or any of your numerous correspondents, would be good enough, through your Journal, to give me a few hints how I may dispose of them to better advantage, you will greatly oblige.—AN OLD SUBSCRIBER.

**WHITE DORKING COCK'S LEGS PARALYSED** (*H. Howell*).—Such paralysis may be the result of age, but it is more frequently caused by a hurt in the back. A blow from a stone or a small switch will often inflict fatal injury to the spine. It may be caused by stoppage. If that be the case, a dose of castor oil will give relief. A full tablespoon will be the dose.

**POULTRY FOOD—ANNUAL EGG-PRODUCE** (*Barndoor*).—Pollard is useful as an adjunct; but the best food for all poultry is ground oats—for a change good barley. The best food is the cheapest. Cochins-Chins, Brahma Pootra, La Fische, and Spanish hens should each lay 120 eggs in the year.

**PHREASANT WITH WING WOUNDED** (*Pheasant*).—If the bone is injured, and if the wound is so serious as to expose the injury, we advise you to amputate. If the bone remains perfect, all you have to do is to keep the wound well fomented, to let out matter that may form, and to exclude the air. If it is at all likely the operation may become necessary, do not defer it too long, it is not so serious as it sounds.

**LIGURIAN BEES** (*Jonas Jackson*).—You are quite right with regard to Ligurian bees losing much of their distinctive colour after death; still, as far as we can judge, those you enclose appear to be the offspring of a hybridised queen. If you will communicate your address to Mr. Woodbury of Exeter, he will be happy to send you a few dead Ligurians, and thus enable you to judge for yourself.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 50.9°, and its night temperature 33.3°. The greatest heat was 69° on the 25th, 1863; and the lowest cold, 14°, on the 25th, 1850. The greatest fall of rain was 1.11 inch.

ROYAL HORTICULTURAL SOCIETY.

FEW weeks ago we expressed a hope, which amounted almost to a conviction, that by the purging of the Council and the introduction of a purer element, the Royal Horticultural Society was about to emerge from its condition of inentity, and to abandon that anomalous course which it has pursued now for some years past.

We have not been disappointed, for, as the season advances, and the Council, aided by the fresh addition it has acquired, gets into full working order, we already see indications that the Society

will yet enjoy its full meed of popularity, and become what it might always have been—the promoter and patron of national horticulture. Those who were present at the first of the scientific meetings, held last Tuesday, must have been deeply impressed with the truth of this statement. Not for many years have we seen so much indication of vitality and vigour as we did on that occasion. The collection of valuable new plants that was brought together for the inspection of the Floral Committee was such as is rarely to be seen in any one place; and the number of certificates awarded was sufficient evidence of the class of subjects exhibited. Of these a report will be found in another page of our present Number.

After the Committee finished their work, at three o'clock the chair was taken for the scientific meeting, at which a lecture was given on the plants or other subjects that were exhibited and received awards from the Committees. This meeting seemed to call forth no small amount of interest, judging from the number of Fellows present, reminding us of the palmiest days of old Regent Street, when the room was crowded with ardent horticulturists, of whom the "passing fair" were not the least conspicuous.

Heartily do we trust to see the Society prosper now that it has started on a nobler and a purer mission than pandering to the lowest of popular tastes, and affecting to hope for success through such a medium. Horticulture in itself, when liberally encouraged, has attractions far exceeding any others that have been offered in past seasons; and we hope, now that a new life has begun in the career of the Society, that all horticulturists will rally round the Council, and assist in making these scientific Tuesdays the most attractive, as they must be the most interesting, of all the Society's meetings. We know of no place where the Fellows or their friends could spend a more agreeable or instructive afternoon than there; and a large number appeared to anticipate this pleasure even at the first meeting of the season that was held last Tuesday.

But for one thing all would be harmonious, and we

sincerely hope that this, which consists in an estrangement between the Council and the exhibitors who object to the Saturday shows, may be removed, and that some basis of reconciliation may be devised, so that this year may be signalised as the resuscitation of the Royal Horticultural Society. The Society is already under a debt of gratitude to Lieut.-Col. Scott, R.E., for the unceasing energy and courtesy he has brought to bear on a work attended with so much difficulty and requiring so much tact and forbearance; and we should be glad to find that he has succeeded in bringing about a better understanding on this subject than at present exists. We believe it is to be done. As in all such cases, there must be a little yielding on both sides—a practising of the old Anglo-Saxon principle of *gif-gaf*, and then all will go on well.

LA CONSTANTE STRAWBERRY.

HAD not the Editors said in a letter to me that they thought that the ventilation of the subject would do good, I should have remained silent. I need hardly say, that I have no interest in the matter one way or the other. "*Magna est veritas, et prevalebit.*"

It is of no use for persons to write up a Strawberry above its merits, or to write it down below its just merits. Had it been stated that La Constante should be in the garden of every painstaking amateur, whose land is of a deep, rich, and loamy nature, not one word should I have said against the statement. In making the statement sent to THE JOURNAL OF HORTICULTURE, I had no desire to entomb such a worthy and valuable sort, when put into painstaking hands, and into soils to which it is adapted. I need hardly say that a "particular" is not a "universal," and that it does not follow, because a Rose or Strawberry does not succeed in one class of soil, that it is to be entombed. Even in the same garden you will find that a Rose that will do nothing under a south wall, will do well under a north one. That is the case with Paul Joseph here. It grows strongly and blooms beautifully close to a north wall. For three years the seven plants have done nothing under a south wall. They are now put back to the north wall. I may say in passing, that here plants winter better under a north than under a south wall. The rains which come from the south-west are driven by the winds over them. Hence they are kept drier, and are also less injured by radiation.

Let me now say one word about hardiness. Hardiness properly must relate both to winter and summer. I must also add spring, when in my situation (a west aspect valley with a high chalky hill facing the rising sun), plants suffer more from the six or eight weeks of severe hoar frosts, than from the severe teeth of zero. I could not grow Pears or Peaches without sheets. These hoar frosts are preceded by a burning sun. Hence radiation, so mischievous to plants, is in the same ratio. It was these hoar frosts, together with chalk in the soil, that for ten years out of eleven destroyed my British Queens. La Constante did not suffer here, when established, from

either of these causes; but in a far less burning summer than the last, it suffered from burning very much. I, therefore, gave it up, determining to reinstate it, should I ever have clay land, to which, when dressed with sandy loam, it is well adapted, and where treated as stated by Dr. Roden, it would answer well. I think as the plant burns in hot summers, a north aspect would be best.

Then comes the question, Does the plant burn in some localities? It did so here, and, of course, it could not run afterwards. I was looking over Mr. Prince's list (Flushing, U.S.), when my eye fell on something that struck me. The catalogue is dated 1863; forty-ninth edition; and at page 8, I read as follows:—"No. 156. La Constante (De Jonghe), regular cone, large, bright crimson; flesh rosy, sweet, exquisite flavour; late, *burns considerably!*" It is no wonder, of course, that in America, a dwarf-habited plant should burn. The silver prize cup previously spoken of as awarded to it in America, by the Pomological Society, was, of course, for its fruit, and I presume without reference to it as a plant. If a plant was presented to the Pomological Society of New York, it was probably a forced plant. I should think that it would be a very good Strawberry to force, and that it would succeed very well. It would also be a very good Strawberry to breed from, if fertilised with such a Strawberry as President.

We want in this country, so diverse in its soils, and so changeable in its climate, Roses and Strawberries with vigorous constitutions to meet so many checks, and of quick growth, and quick establishment. Anything in the way of a plant that does not answer to the above is of no use to me. Annual plantations in first-class lands, and under able hands, may be practised successfully. The plants, however, must be put in early. Mr. May, of Blandford, the best Queen grower I ever saw, took two runners per plant from his British Queens during fruiting time, pegged into a pot. Hence he got his annual plants in early, which, in such fine land, fruited heavily. I have, however, seen in his garden a magnificent crop of Queens roasted, and the foliage burnt up. I found here that the easiest to cultivate of the three recommended by Dr. Roden, was the Carolina Superba. It was not at all tender. The plants and "brimmed" leaves were strong. I discarded it, as it did not crop sufficiently to repay me. So many people come to eat, twenty-five at a time, that I must have hardy sorts, good, and good croppers.

Now, as I have put in THE JOURNAL OF HORTICULTURE what Mr. Taylor has said, it is but fair to put in what Mr. Standish says. I received the following from Ascot Royal Nurseries a few days ago. It will be read with interest, and I make no apology for extracting from a kind letter, ending with an invitation:—

"Certainly La Constante is one of the most hardy kinds known. Mr. de Jonghe showed me letters from Russia, Germany, and all parts of the world, stating its hardiness, and my experience here confirms it, this being a very cold place. Dr. Hogg was here the other day, and coming across the heath, he told me he thought the wind would have cut his ears and nose off. I have a lot of Strawberry plants in the ground in beds on ashes. I have several thousands of La Constante, President, Oscar, Sir Charles Napier, and others. La Constante and President are the hardiest. The leaves of both are as green as in summer. The leaves of the others are cut in a very marked manner, and quite dead." He then goes on to say, that "he has fertilised La Constante with the British Queen with a view to get size, flavour, substance, hardiness, and productiveness; that he bred and fruited about five hundred seedlings from La Constante crossed by the British Queen; and that although the May frosts injured a good many of them, there were some wonderful crosses with all the size and flavour of the British Queen, and the fine colour of Sir Charles Napier, and, very curiously, there were scarcely two plants alike. "I shall have about two thousand seedling Strawberries, and shall be very pleased to see you at Ascot, to stop as long as you please, or till you are tired of tasting Strawberries."

The above kindness I much appreciate. Well, let us hope, then, that with La Fertile, and Modèle, and others, we shall have an accession to our fragarium that will stand the burning heats of summer and the rigours of an English winter. I trust that in the above article, and also in all

preceding ones, I have not expressed myself offensively, nor thrown myself open to suspicions of sinister motives.—  
W. F. RADCLIFFE, *Tarrant Rushton, Blandford.*

## BRICK STOVES.

NOTHING can well be more simple than a brick stove. A bricklayer who could hardly set a washhouse boiler could easily build a square of bricks with a square opening in the middle and two openings in front, one for the ashpit door and one for the furnace and feeding door, and then a third small opening, either on the other side or at the top, for letting the smoke out; the latter if a damper is not used is the best, as the object is not only to heat the stove, but to keep the heat about it as much as possible. All these stoves do better if the horizontal pipe is short, say about 2 feet, and then in general the upright pipe will not require to be long.

To please two or three other correspondents as well as "A. Q.," we will describe how to make one of these small stoves, say 28 inches square outside measure, and 46 or 48 inches in height, an inch or two more in height, even, we consider to be an advantage. If your chimney is to be inside your horizontal pipe may be less than 2 feet from the stove before entering the chimney. We will suppose it to be 2 feet, and therefore will begin at that distance from the wall, and also because the stove will give out more heat than if one side of the stove were formed by the back wall. Mark out the square of 28 inches, and cover that space with brick-on-bed. This forms the base, and the ashpit door will thus be the thickness of the brick above the floor. In the front and middle of this set up the ashpit door (one with a ventilator in it is the best), build up the rest, leaving opposite the door a space 8 inches wide, and say a foot long, and some 8 inches deep, and above that lay the bars and set up the furnace door. It will be best to have the furnace door and ashpit door all fixed in one. There will be holes for hooked pieces of iron to go in, which, carried into the brickwork, keep the doors firmly in their places. A fire-box, 8 inches square and 8 or 9 inches deep, formed of fire-lumps or fire-brick, should be placed at the side of the bars, and this box with outside bricks makes it often desirable that the ashpit door and the furnace door should be in separate pieces, as the bottom of the furnace door should be about the same level as the top of the fire-box. This allows of a facing of bricks between the two doors and round the fire-lumps. Raise the walls to the requisite height with brick-on-bed, leaving a hole 4 inches in diameter for the pipe, and say from 5 to 7 inches from the top. The top is best made of an iron plate from three-quarters to an inch thick. The heat rising will strike against the plate and be thrown back again on the brickwork before it escapes by the pipe. To make it more difficult for the heat to escape the front of the opening should have either an iron plate or a thin fire-lump set up on the top of the further side of the fire-box, and about 2 inches from the pipe, forming a sort of chamber in front of it, with openings on both sides between the plate and wall for the smoke to pass. This tends to keep the heat more confined in the stove. With this precaution, a close-fitting furnace door, and close-fitting ashpit door, with a small ventilator in it, a damper in the chimney will scarcely be necessary. In one or two cases where the ashpit door had no opening we advised a small hole half an inch in diameter to be drilled and supplied with a wooden peg, and regulating that gave sufficient draught after the fire was burning. In cleaning out such fire-boxes they should be damped previously, and then for ease, if the grating is hung on pivots so as to fall when desirable into the ashpit, as described in Vol. XXV., page 134, it will be a great help.

Such a stove would be useful for excluding spring frosts and ripening the wood in an orchard-house from 30 to 35 feet in length and 10 or 11 feet in width. If more were wanted the stove would require to be larger and the fire-box larger, or two stoves would have to be placed in the house.

The iron plate being flat an iron vessel of water can be placed on it. But for that in your case you might have a hole in the iron in the middle, and place your chimney inside the house upon it, bringing it against the north wall and taking it through the wall near the top. This

would be a simple mode, and then you would require a damper to fit the chimney nicely. One of the best to use would be a thin iron plate with two or three holes in the centre, in the line of draught, from a quarter to three-eighths of an inch in diameter. Pull out the damper when you lighted your fire, and when the smoke was pretty well gone, put it in home, and the holes would give enough of draught for coke, and the damper would send back the heat again and again over the stove. We would place the damper high enough to be reached from the floor. Coke only should be used, and broken.

As stated in "Doings of the Last Week" lately, you will be more safe to keep the blossom back in such a house, and only use your stove to keep the trees safe from frost. If you do more it would be advisable never to make the heat higher than 50° in dull weather, and from 45° at night would be high enough, unless you wished to force. In dull autumns a dry heat will be useful. If the iron plate become very hot you may cover it with brick. The higher the plate is from the fire-box in moderation the more equally will the heat be diffused from all parts of the stove.—R. F.

### PLANTING A WASTE SLIP OF LAND—MODES OF HEATING.

WHAT vegetables or fruits will thrive on a narrow slip of ground fronting the north-east, bounded by a house on the one side, and a hedge on the other? Last year my predecessor planted it with Jerusalem Artichokes, but I question whether it has returned the seed.

I should like, also, to have a word about a hot-water apparatus that is beginning to attract some attention in your pages—I mean Mussett's. If it is what it professes to be it must be invaluable to small amateurs like myself; but it is quite contrary to the scientific principles laid down for years past in your Journal. I have been taught to believe by its pages that you cannot obtain more heat out of a fire than there is in it, and that in warming a house by the best-constructed apparatus, much of the heat is wasted.

How is it, then, that a couple of lamps should be able to warm a whole house, not to say "chapels, churches," &c.? For my own part, I have just put up a small house 10 feet by 8, and so little faith have I in Mussett's apparatus that I have ordered about 50 feet of three-inch pipe, which alone exceeds the cost of Mussett's. Do you not think you could say something simple and elementary on the subject of heating, which would be a guide to simple folk like me?—A REGULAR SUBSCRIBER.

[If the Jerusalem Artichokes did not flourish on the narrow strip of ground, fronting the north-east, it must have been owing to the poverty of the ground, or the confined space, surrounded by house and hedge, as this Artichoke will thrive almost anywhere. To have it nice this Artichoke should be planted every year, the same as Potatoes; for, though it will maintain itself in the same ground for a generation, the tubers are not so nice, nor yet so soft when boiled. Such a place would also do admirably for Rhubarb and Sea-kale, and for Lettuces and salading in summer. As to fruits, it would be a valuable corner for late Strawberries of the Elton or other kinds, and also for Warrington or other late Gooseberries. From such a corner you might have Gooseberries to the end of October, and good, too, if properly netted or canvassed, to keep wasps and flies from them. Currants could also be kept there late, and the Double-bearing Raspberry. Late Pears and Apples would also do, but not so well as the small fruit.

We can add very little to what we have said in previous weeks relative to heating small greenhouses in winter. No doubt a little allowance must be made for the enthusiasm of inventors and tradesmen, each of whom may rightly and conscientiously believe that his own particular mode is by far the best. Every man feels and acts in the same manner every day, though he may do it quite unconsciously. There is a vast difference between a thorough enthusiasm and the lines that approach dishonest misrepresentation; and the older we grow, if we do sober down the enthusiasm a little, we also feel less sceptical as to the thorough belief of the enthusiast in his own representations. Not so long ago one

who has had much experience in such matters, candidly told us that such and such idea, if reduced to practice, would pay well, "if sufficiently cracked up." Now, it is quite true that without this "cracking up" even good inventions will be apt to remain the sole property of the inventor.

In heating there has been little that is really new. A small fire beneath the floor is as simple and as good as any other contrivance. A pipe from a kitchen boiler, if the boiler is close, and the kitchen is on a lower level than the greenhouse, is also a very simple plan. A small iron stove, especially if the sides are double, or the fire-box about 4 inches from the single side, and a pipe through the roof, is also very simple; but the fire must be lighted inside, and care must be taken that the sides do not approach red heat. A brick stove is better than an iron one, because the bricks do not become so hot, and they retain heat longer than the iron, but then they cannot be removed like an iron stove; if placed against a back wall they may have plants set on them, or in front of them, in summer, or otherwise be concealed.

We have not tried Mussett's apparatus ourselves, but we have no doubt that it and Riddell's stove and boiler would answer admirably for small places. In one respect such an apparatus or boiler is better than a mere stove heated by a candle, lamp, or gas—namely, that the iron, being surrounded by water, will never become so hot as to be unhealthy to plants by burning the particles of dust, and consuming the oxygen of the enclosed air. It is on this account that we object to the continuous use of any stoves in plant-houses, with or without prepared fuel, where there is not some outlet into the open air to carry off the results of combustion. Such stoves, whatever their name, are less or more modifications of the stove and fuel, without any chimney, invented by Mr. Joyce nearly thirty years ago. Such a stove would be useful in large halls, in passages, &c., where there is a constant change of air from the opening of doors. In small close-glazed conservatories they are only less dangerous than frost, and might be used in extremes. In large conservatories, or where the glazing and the laps are open, such a stove would help to keep out frost, and the continuous admission of fresh air would prevent any or much injury being done. The prepared fuel would be an advantage in a small house, and no objection would exist if there were a small pipe to take off the results of combustion, farther than the care necessary to prevent the sides of the stove becoming too hot. We have known such stoves used in halls, warehouses, and shops with but little apparent bad effects; but then the air is more frequently changed than it is possible to be during a cold night in a close-glazed greenhouse. Even with the prepared fuel we consider such stoves more dangerous for tender plants than stoves or little boilers heated at once by lamps, candles, or gas, as, if carefully tended, little that is deleterious will be allowed to pass into the house. Even in their case, however, a small pipe going from the stove, or the funnel above the burners, will take but little heat outside, whilst it will insure safety from any effects of combustion.

We quite agree with our correspondent as to excessive enthusiasm in talking of heating whole houses, chapels, churches, &c., by means of a couple of lamps, a few jets of gas, &c.; but that is no reason why a couple of lamps should not heat a small house, no larger than a small room, as his own house, 10 feet by 8. It is so well known that a number of jets of gas will heat a church that, in severe weather, where there are no other means of heating, the gas is lighted an hour or two before the worshippers arrive. In the evenings, too, the heat from the gas renders the atmosphere oppressive, and especially if there is not a sufficient ventilation from the roof. We quite agree with our correspondent that only a certain amount of heat can be obtained from a certain amount of fuel, but we scarcely ever economise that heat sufficiently. We wilfully or ignorantly consent that a large amount of the heating power shall be wasted. Now, in many of these little stoves, with or without hot water round them, an attempt is made to obtain more than the usual quantity of heat from fuel or flame of any kind, just by preventing it exerting itself much on the external atmosphere. We could not pronounce a definite opinion upon any of these little stoves or boilers, without carefully working them all at the same time; but our

previous experience leads us to the conclusion that, if we did not demand too much from them, we should make them all answer well.]

### DEARTH OF GOOD HORTICULTURISTS!

IN your recent report of the annual meeting of the Royal Horticultural Society Mr. Bateman is represented to have stated, as the reason why there are not more horticulturists on the Council, that there never was such a great dearth of good horticulturists as at the present time!

Is it possible this was correctly reported? My own impression had been that we never had so many! and I therefore hope to hear that it was an error on the part either of your printer or reporter.

In the interest of the science pray inform me in your next Number, and oblige your attentive reader—J. C. C. (I enclose my card.)

[Our report was quite accurate, and Mr. Bateman has given great offence to the horticultural community, who most assuredly do not deserve such a censure. We believe that there are more good gardeners, amateur, as well as professional, and more good gardening now than at any other period.—Eds.]

### ROYAL HORTICULTURAL SOCIETY.

MARCH 7TH.

**FLOREAL COMMITTEE.**—The first meeting of this Committee was held on this day in the Society's garden, South Kensington; there was a full attendance of the members, and a great many interesting plants sent for examination.

Mr. Veitch, Chelsea, exhibited a large miscellaneous collection of plants, which added much to the interest of the meeting. Among this collection several plants received certificates, both as novelties and as well-grown specimens. It was quite encouraging to hear the gratification expressed by several of the Fellows present at seeing so fine a display of plants; and it is much to be desired that others of our leading nurserymen would occasionally follow Mr. Veitch's example, by sending collections of miscellaneous plants, or a series of such as represent any particular family. We would remind the Fellows of the Society, also, how much they might contribute to the interest of these meetings if they would send any plant or flower for exhibition which bears any special interest. Among the Orchids in Mr. Veitch's collection which received special notice, was a new *Cypripedium*, *lævigatum*, from Manilla. This is a very distinct and handsome species; the upper segment of the flower white, with dark veins; under lip yellow, with long, brownish, narrow, waving, side petals; the foliage very handsome and bright green. This received a first-class certificate. *Angræcum* species from Madagascar was a very pretty small Orchid, growing on a portion of a stake of wood, and having a white spike of small white flowers bearing a conspicuous spur. *Cattleya Pilcheri*, one of Mr. Dominy's hybrids between *C. crispa* and *Lælia Perrinii*, promises to be an interesting variety, and the Committee requested to see it again. *Phalænopsis Schilleriana major*, with beautiful broad mottled foliage, the flowers much larger than those of *P. Schilleriana*, and of not so deep a colour, received a first-class certificate. *Odontoglossum Pescatorei splendens* had a similar award. This most elegant Orchid is one of the cool-house section; the plant exhibited had flowered in a house with a temperature varying from 40° to 45°. Mr. Veitch also exhibited *Lælia Lindleyana*, white flower with pale purple lip, narrow upper and side petals—first-class certificate; *Barkeria Skinneri superba*, with bright purplish rosy spikes of flowers, which were abundant—first-class certificate; *Cattleya Warszewiczii*, only one flower on the plant to be seen; *Lycaste Skinneri alba*, a distinct variety with a pure white lip, giving the flower a very delicate appearance; Seedling *Rhododendron Princess Alexandra*, the flowers white on dark red footstalks, highly scented, in the form of *jasminiflorum*—first-class certificate; and *Cytisus filipes*, an old plant, useful for table decoration, for which it received a special certificate. This elegant and graceful plant, with its racemes of white and yellow flowers, was much admired. A special certificate was awarded to

each of the following plants, sent also by Mr. Veitch:—Collection of *Lycaste Skinneri* of endless variety, specimen plant of *Cœlogyne cristata*, *Phalænopsis Schilleriana*, *Camellia Roi Leopold*; and one for the general collection sent, including *Hyacinths*, *Narcissus*, &c.

Mr. Wilson Saunders had *Cotyledon* sp. from South Africa, resembling *Cotyledon orbicularis*—the plant produced a cluster of brownish-red flowers on a tall stem growing from the centre of thick fleshy leaves, interesting only as a curious plant; also a hybrid seedling *Sonchus* between *S. arborea* and *S. gummifer*. This plant had beautiful translucent dissected foliage, forming an elegant plant for table decoration, and as such received a first-class certificate. A species of *Brassavola*, sent to the Society by their collector Mr. Weir, and supposed to be *B. nodosa*, was also shown. Mr. Bateman contributed a superb cut spike of *Phalænopsis Schilleriana*, with about forty beautifully expanded flowers—special certificate; *Dendrobium Wallichianum*, a cut spike of this plant thought to be wrongly named; *Dendrobium hedyosmum*, a dwarf plant with white flowers having a yellow lip, remarkably sweet-scented, for which property it received a label of commendation.

Mr. Marcham, Hanwell, sent three seedling *Cinerarias*; Mr. Gibson a cut specimen of *Nicotiana wigandoides* with greenish-white flowers; Mr. Standish, Ascot, *Camellia reticulata flore pleno*, a very handsome, large, deep crimson flower—first-class certificate; *Camellia Reine des Beautés*, a very reflexed, pale-shaded, flesh-coloured flower of exquisite form, bright green foliage, a perfect gem—first-class certificate; *Corylopsis spicata*, a hardy Japanese shrub with pale yellow flowers, scented like the Cowslip—beyond its being an early spring-flowering shrub it has no claim for particular notice—and a small plant of *Aucuba japonica vera*, with beautiful bright scarlet berries. Mr. Bull exhibited an interesting collection of *Aucubas*, discovered by Dr. Von Siebold, many of them female or berry-bearing varieties, with very handsome foliage. Most of the plants were very small, too small to enable the Committee to decide upon their merits. *Aucuba macrophylla*, a very large, broad, green-leaved variety—first-class certificate; *Aucuba mascula elegantissima*, the leaves with broad, yellow, central markings, bordered with green—first-class certificate; *Aucuba latifolia femina*, a very dark glossy green-leaved variety—first-class certificate; *Aucuba bicolor*; *A. sulphurea*; *A. lancifolia mascula variegata*, with pale green variegation; *A. mascula angulata*; *A. mascula elegans*, smaller foliage than *elegantissima*, different shaped leaf; and *A. himalaica*, bearing unripe berries on long and loose footstalks. Mr. Todman, gardener to Mr. Hodson, exhibited seedling *Azalea* Dr. Lindley, deep rose, smooth-edged flowers, of good substance; Lord Palmerston, rose, with faintly-spotted centre; Lord Stanley, orange scarlet; Mont Blanc, a semi-double white flower, inferior to Flag of Truce. The plants were small, and there were not sufficient flowers to determine their merits; there appeared to be nothing new among them.

Mr. Graham, Cranford, exhibited a seedling *Violet*, The Czar, with very large flowers, highly scented; dark, robust, green foliage. Some discussion arose as to its identity with other *Violets*—namely, The Giant, *Devoniensis*, and *Russian Improved*. It is a valuable seedling from whatever parent it sprung, and was awarded a first-class certificate.

**FRUIT COMMITTEE.**—George F. Wilson, Esq., F.R.S., in the chair. Mr. Wills, gardener to Sir Philip Egerton, Bart., Oulton Park, sent a seedling *Apple* raised near that place, and called Oulton Russet. It is a handsome-looking medium-sized fruit, somewhat flattened in shape and ridged round the apex. The flesh is tender, and has a very pleasant flavour. The tree, Mr. Wills says, is "one of the most constant fruiting kinds he knows; for four seasons they have borne good crops of Apples." The opinion of the Committee was that it is a good *Apple*, but that the flavour was apparently passed, and that they would like to see it again earlier in the season. Mr. Dwerrhouse, gardener to Lord Eversley at Heckfield, sent five specimens of *Bergamotte Esperen*, which were evidently from an orchard-house; but as no letter nor name accompanied them, the Committee did not know the circumstances under which they were produced. They were accompanied by specimens of apparently the same variety grown out of doors, but which were very inferior in size and appearance.

Mr. John Shaw, nurseryman, Manchester, sent a collection of a new sort of tallies for naming trees and shrubs. They consist of plates of polished zinc, of various sizes and ornamental shapes, and the names are engraved deeply in the metal, the space being filled with a black substance, thereby rendering the name clear and distinct. The Committee approved of these, and considered them well adapted for the purpose, provided the black substance remains permanent, and the polished surface does not become so tarnished as to render the name indistinct. Mr. William Earley, gardener to F. Prior, Esq., of Digswell, also sent a label for trees and shrubs, which consisted of thin plates of zinc painted white, and the name cut through in the way of a stencilling plate.

After the meeting of the Committees the Scientific Meeting was held at three o'clock, W. Wilson Saunders, Esq., F.R.S., in the chair. The room was well filled with Fellows, of whom a considerable number were ladies. The Chairman congratulated the Society on a return to these meetings, which had always been so attractive and attended with so much interest at Regent Street, and then proceeded to comment on the programme of the year. He stated that it was the object of the Society now to promote in every way the advancement of horticulture, and for this end all its resources would be called into operation. The garden at Chiswick would this year be devoted to very extensive experiments both in fruits, flowers, and vegetables, and everything would be done to enable the Society to carry out the legitimate objects it was instituted to foster.

The Rev. M. J. Berkeley then delivered a lecture on the various plants that were exhibited before the Floral Committee, and Rev. Joshua Dix made some observations on the florists' flowers.

#### WEEKLY SHOW.—MARCH 11TH.

ON this occasion Messrs. Lee exhibited fine plants of *Cordylone indivisa*, *Davallia tenuifolia*, with very graceful finely-divided fronds, *Cyathea Smithi* about 6 feet across, and *Oncidium Phillipsii* in excellent bloom. From Mr. Bull came a small collection of flowering plants and Camellias *Contessa Ottolini*, a finely imbricated rose with broad and handsome foliage, and *Raffii* deep rose; also *Anthurium leuconeurum* and one of his ornamental stands for the drawing-room. Mr. Coys, gardener to E. Wood, Esq., Rugby, contributed a well-bloomed plant of *Deutzia gracilis*, *Thysacanthus rutilans*, and a mixed collection of flowering plants, whilst Mr. Lucking and Mr. Greeves sent window-baskets, bouquets, and flower-baskets filled with Hyacinths, and other early flowers.

#### PRIZES PAID BY THE ROYAL HORTICULTURAL SOCIETY.

I HAVE recently received from the Accountant of the Royal Horticultural Society a letter, stating "the pleasure which he has in enclosing me 7s. 11d., being the amount of my prize account for the last two shows." I exhibited at the first of these shows, and obtained first-class certificates: first for Pears *Beurré Langelier*, *Catillac*, and *Beurré de Rance*; second for "the best large table Potatoes, the variety *Lemon Kidneys*, a very handsome and excellent Potato" (I copy from their report); and at the last of the shows I obtained third-class certificates for Apples and Turnips.

Now, with many other gardeners who exhibited, I believed that I should have medals to show my success, and probably a trifle in money. The pleasure which is expressed in sending me 7s. 11d. for my four certificates is not felt by me in the receipt of the money. Surely some explanation should be given as to the mode of payment and how it is calculated. If half-a-crown had been sent to me I must either have received it or rejected it. Success at two shows with no medal and 7s. 11d. only in money will hardly attract exhibitors to the high-sounding Royal Horticultural Society. It would be well if the Society would forward to you for publication what is the average value of their different certificates, and in what cases only medals are distributed, and also the amount of their receipts for admission, and the scheme

upon which the money was divided amongst the exhibitors. Unexplained, the prizes are not worth competing for.—H. BENTLEY, *Gardener to Lord St. Leonards, Thames Ditton.*

I MUST inform you that the Royal Horticultural Society sent me 2s. 3d. worth of stamps for a first-class certificate for a Queen Pine, and a third-class certificate for six dishes of kitchen Apples exhibited at the Great International Fruit Show in 1864.—THAMES DITTON.

[No remark is needed to increase the ridicule felt at such awards; but we rejoice to be justified in adding that an entirely new spirit is gradually being infused into the management of the Royal Horticultural Society, and though why those awards were so contemptible may be explicable, yet we think in future there will be no need of any such explanations, as a much more dignified policy has already been inaugurated.]

#### VISITS TO GARDENS PUBLIC AND PRIVATE.

MR. W. BULL'S, EXOTIC NURSERY, CHELSEA.

IF "variety is pleasing," as we used to be taught in our boy days, when undergoing our preliminary instruction in round hand, then ought Mr. Bull's life to be one of unmixed gratification; for so little reverence has he for what is old and well known, that, save in the matter of large specimens, these qualities would be an absolute disqualification for any plant that sought admission into his establishment; but let it have but the recommendation of novelty combined with merit, and then it matters little from what portion of the world it comes, or for what it may be remarkable, it will find there a home. After my stroll through Mr. Veitch's the other day I spent a short time with Mr. Bull, and have here to record a few things that struck me on going through his numerous plant-houses. At this time of the year I need not say they present a very different aspect to what they do later in the season, and that one must not expect to see any gorgeous display of flowers. The mere loiterer, who can admire a blaze of colour or be captivated by a fragrant perfume, must not expect to be gratified just now; but those who want to know what new treasures skill and enterprise are adding to our horticultural stores will here find much to interest: especially is this the case with what are called fine-foliaged and variegated plants, to which Mr. Bull is continually making additions, and of which many interesting examples are now in his establishment.

As I some time since recorded my general impressions of Mr. Bull's nursery, my notices now must be brief, and pertain simply to those things which strike me as likely to be valuable additions to our already ample stores. Thus, for example, we have heard a great deal lately of the *Aucubas* from Japan, and probably no plant has had more distinguished honour conferred upon it than that fine plant of the female *Aucuba* in full berry. Very interesting, therefore, were some varieties of variegated *Aucubas* which Mr. Bull has received from the continent, the introduction of *Von Siebold*. The golden variegation is not, as in the common form, spotted all over the surface of the leaf, but in large blotches of gold colour; and we can hardly conceive anything more beautiful than would be one of these fine varieties when grown into a large bush. There can be little doubt that these Japanese introductions will make quite a revolution in our gardens ere long. There was also a very beautiful golden-variegated *Elæagnus*. Nor must I omit the beautiful variegated *Pampas Grass*. Striking as is the normal character of this plant, it will receive no inconsiderable attraction by this beautiful and distinct variegation. Then there were the very fine gold and silver variegated *Rhodeas* from Japan. Handsome, too, are some of the *Acers* from the same country; conspicuous amongst which was *A. pseudo-Platanus Leopoldi*, green with crimson and rose variegation. Then there was a very fine variegated *Verbena* which is to be sent out in April, called *Popular*, in which the leaves are clearly marked with a regular yellow variegation, and having bright scarlet flowers; and also a silver-variegated *Pompon Chrysanthemum* called *Sensation*. Both of these plants will, I think, be considered acquisitions by those who are fond of such things. Nor must I omit two plants not yet out—a variegated variety of *Aubrietia*

purpurea, in which the marking was very regular and clear; also a very pretty *Sedum* of the same character. The variegation even descends to Ferns, for there was a distinctly variegated form of *Aerophorus hispidus*, and a new variegated *Pteris*, something between *P. cretica albo-lineata* and *P. serrulata*.

Amongst the rarer stove and greenhouse plants, of which Mr. Bull has a large selection, I may mention the fine *Anthurium* to which I have already alluded in Mr. Veitch's collection as introduced by Mr. Weir from South America; also the pretty *Paperomia arifolia*, with beautiful wax-like leaves and beautifully variegated. I have already alluded to the fine varieties both of *Dracæna* and *Pandanus*, so very useful for in-door decoration. *Ouvirandra fenestralis*, the Lace-plant of Madagascar, will now be generally grown, and was to be seen here in small plants ready for distribution. Then there is the curious *Cephalotus follicularis*, sufficiently hardy for ordinary greenhouse culture.

Amongst Ferns I noticed a crested variety of *Nephrodium molle*, *Adiantum Fééi*, the crested variety of *Polystichum angulare*, and the new forms of *Athyrium Filix-fœmina*, *Vernonæ* and *Victoriæ*. *Lastrea Standishii* can hardly be called a new Fern now, but it will certainly for a long time be valued as a handsome and free-growing one.

Of the numerous softwooded plants—the *Petunias*, *Pelargoniums*, *Pentstemons*, it would be premature to speak. We can only look forward to seeing them by-and-by, and reporting in due time; and that we may have to report favourably of many is, I think, most likely, for unquestionably in *Editor*, *Clipper*, *Miriam*, *Lorenzo*, &c., we have had flowers of decided merit. Nor must I forget that Mr. Bull has a large quantity of the fine *Lilium auratum*, of which he has a consignment of upwards of 2000; while he has also been successful in obtaining a very clear and distinct variety in *Lilium auratum rubro-vittatum*, in which the golden band gives place to one of deep red, and it is quite possible that amongst the more recent arrivals may be found other varieties. From these two establishments, Mr. Veitch's and Mr. Bull's, different indeed in character, one may gain an idea of the great amount of enterprise which the present taste for horticulture has called forth.—D., Deal.

#### TURVES FOR STRAWBERRIES IN POTS.

In your No. 204, page 156, Mr. Abbey says, "Never use saucers, they rot the roots by keeping the soil sour; use sods in preference, the turves being placed on the shelves grass side downwards." Last year I placed about one hundred Strawberry plants in pots on shelves in my orchard and cool Vine-house (seldom heated), in this manner; the rest of the pots in saucers. Two days after I was told by a very experienced gardener that those on sods would be totally destroyed by wireworm, and I at once removed them into saucers. I had four kinds of Strawberries—the British Queen, Keens' Seedling, Black Prince, and Empress Eugénie, all of which produced good crops. My gardener is now bringing my Strawberry plants in pots into the cool Vine orchard-house, and I shall have a portion of them placed on turves in consequence of Mr. Abbey's recommendation, some also in saucers, and a few as an experiment in a shallow trough of zinc filled with sand, to compare these different modes of culture.—E. S.

[I object to saucers on the ground of their being kept full of water mainly during dull weather and the early stages of the plants' growth. I have found saucers more prejudicial than beneficial, unless you water the plants yourself, or have assistants equally careful. The saucers are of no use until the fruit is set, all that is needed is a cool and moist bottom to counteract the drying influence of artificial heat on the pots, and, consequently, on the roots. After the fruit is set a good supply of water is necessary to make the fruit swell well, and there is less probability of the plants suffering for want of water when standing in saucers than when standing on the bare shelf, and they, by holding water, assist in keeping the air about them cool and moist, and are more desirable after the sun gains power than early in the season. I never found Strawberries do well in a wet undrained soil, but find them do best in strong soil deeply stirred which will let the water through it and out at the

bottom. I never saw or found the Strawberry, wild or in a cultivated state, growing in a marsh or bog, and for these reasons I take it for granted that saucers may lessen the necessity of watering the plants, but they give a soddened and sour soil not congenial to the growth of the roots. With sods the case is entirely reversed. They furnish a cool bottom; the atmosphere is kept moist around the pots through the evaporation from the turves; the roots make their way into them; any one can water the plants without fear of making the soil in the pots sour; and the plants derive nourishment from the turves. On sods the plants can never be watered too much, for the soil will hold no more than its retentive power permits, and that is all that is necessary for the plants at the time. When the saucers are not used, or the water not allowed to remain in them for any length of time, then none of the evils of keeping them constantly filled present themselves; and there is less likelihood of harm when the saucers are used at a later period, for the sun having more power a more constant supply of water is needed. With careful watering Strawberries do well in saucers, but these are of no use until the flowers open, and ought to be emptied an hour after watering. Troughs to retain water are just as bad as saucers, though I know both do well for swelling fruit; but the danger is the same in both—viz., with careless watering at the early stages the plants are apt to become too wet, and the roots rot instead of multiplying. I have used turves for many years, and how long they were used before my time I cannot tell, but I never heard of any complaints of wireworms doing injury to the plants. Perhaps I make the soil obnoxious to them, by strewing a little soot over the rough soil placed over the drainage at the bottom of the pots when potting the plants into their blooming pots, or drive them out of the sods by saturating them with soot and manure water. I use the sods on which the plants are placed for potting the plants intended for forcing another year, and what is to spare forms, with the addition of one-third leaf mould, an excellent compost for *Pelargoniums*, *Cinerarias*, *Calceolarias*, and the like.—G. ABBEY.]

#### VARIEGATED BORECOLES AS WINTER BEDDING-OUT PLANTS.

Will you tell "K. D. T." what time the *Brassica oleracea proliferata* should be planted for winter bedding, as it is described as being so pretty at Miss Hope's, of Wardie Lodge, in your Journal of February 21st? Should it be transplanted according to the colours the leaves become, or sown at once where it is to remain?

[Were we to make beds of the variegated Borecoles, we would sow in April, and prick out the plants on a border or quarter about 15 inches apart, and lift and arrange them according to colour as soon as the summer bedding plants were removed. Some of the whites, purples, and nearly reds, are very pretty; but there is no question that however beautiful they may be, they suggest ideas of the kitchen, just as a row of dark-coloured Beet does.]

#### PLANTING RAISED BEDS—SOWING PERILLA.

I INTEND having two match oblong-beds, which to suit the situation, require to be raised as much as possible. I thought of planting one of them with *Calceolaria* for centre, a band of *Perilla* next, another of *Scarlet Geranium*, with a slight edging of some white plant. Could each different colour be raised a little above its neighbour, to produce as good an effect as if planted in the common way? If the bed is much raised to the middle in the shape of a mound, the water runs off. Can you say how a bed would look with *Perilla* for the centre, with four lines of *Cineraria maritima* running through it at equal angles from the middle? Would this style be effective, applied generally, not to the plants I have quoted in particular? I should like to know also, the proper time to sow *Perilla* seed, in order to have good early plants.—F. T. C.

[It would be advisable to plant your match oblong-beds in the same manner—that is, if they must pair, such, for

instance, as being placed one on each side of a walk or an avenue of grass. Your proposed planting of yellow Calceolaria for centre, Perilla on each side, and then Scarlet Geranium, bordered with Cerastium, or Cineraria, would look very well. Unless your Calceolaria is a strong one, we would prefer the Perilla for the centre, as it would give less trouble in nipping, &c. You do not say what the width of the beds is, but supposing they are 10 feet wide, you might safely raise the centre from 24 to 30 inches. Your lines will show all the better in consequence. The difficulty as to the water running off may easily be neutralised by surface-stirring and then mulching with rotten dung or leaf mould, or cocoa-nut refuse. We find that in such raised beds the plants put highest need the least watering, owing to the roots having a greater depth of soil. If you put Calceolarias at the ridge, they will need mulching as soon as the sun has warmed the ground sufficiently. Crossing and Vandyking such beds as you propose will also look well, especially from the sides. The straight rows will be most telling from the ends, and easiest done. Sow Perilla seed in a hotbed before the end of March.]

LONICERA AUREO-RETICULATA.

CHRYSANTHEMUM STEMS KILLED BY BURNING SULPHUR.

On the 7th of October last, I had an accident with a sulphur-fumigating apparatus which I invented, and, in consequence, destroyed the whole contents of my greenhouse by the fumes. Amongst the rest there was a lot of fine Chrysanthemums (including the Japanese varieties), just coming into bloom. The leaves and stems of these were all killed. The plants have since sent up fine shoots, which are now from 12 to 18 inches high, and look as if they would flower now. Had I better cut down the stems and make cuttings from them, as is usual at this period, or let them flower?

Enclosed I send you a piece of the Japanese creeper, *Lonicera aureo-reticulata*, it had originally a smooth-edged oval leaf, deeply veined with golden network. It was killed, or rather its leaves were, by the sulphur fumes, and now the leaves appear with an indented edge and minus the veins, or least with very small ones. Is not this rather a curious effect?—SIGMA.

[We are rather doubtful as to your Chrysanthemums flowering now, but we would take off some pieces for cuttings or little plants, and let the rest remain until you see what they will do. If by retarding or cutting down in October we could have bloom in March and April, it would be a good acquisition. By all means, let some, at least, of the plants remain, and let us know the result.

The slip sent is so unlike the *Lonicera aureo-reticulata*, that it is possible something else has come up in the pot. The leaves, also, seem more herbaceous than shrubby. It is possible, that from shooting strongly and vigorously it has taken the present appearance. If so, it will revert to the original type as it grows older. You have learned one important lesson—namely, never to use burning sulphur where there is anything green.]

LIST OF FLOWERS.

I, too, would enter my caveat, with my good friend "P. H. G." (who, I am glad to see, has escaped alive from those monsters of the deep, into whose domestic arrangements he has been prying for the last twelve months), against the very loose and indefinite manner in which one is asked for lists of the best flowers, and in consequence of which the answers must often be very unsatisfactory. A correspondent, e.g., wants the names of the best twelve Pelargoniums. Now, these vary in price from one guinea to one shilling. If I send "Inquisitor" or a "Constant Reader" a list, in which, perhaps, John Hoyle and Mary Hoyle, and British Sailor figure, I should be told he did not mean new varieties, they are beyond him; while, if I take the older sorts, "Oh! I have all those," is the rejoinder. It would, then, be a great help to us, when asked for such lists, if querists would be kind enough to say—1st, Whether price is an object; 2nd, Whether they have any of the

flowers about which inquiry is made; 3rd, Whether they are wanted for exhibition purposes, the home greenhouse or garden, or for decorative purposes generally. And then they must also remember that judges differ as to which are the best flowers out. My opinion may be different from my neighbour's; he may admire size, while I prefer symmetry; or he may think colour the main point, and I hold that colour, without substance, is worth nothing; hence two persons, equally trustworthy, may give very different lists. With this caveat I reply to "R. T."

*Best Eighteen Show Dahlias.*—Alexander, white tipped; Beauty of Hilperton, purple; Bob Ridley, bright red; Caractacus, yellow, with red tip; Charlotte Dorling, white, edged with crimson; Charmer, yellow buff; Golden Drop, yellow; Lady Douglas Pennant, primrose; Lady Popham, white, tipped with lavender; Lord Derby, bright rosy crimson; Donald Beaton, shaded maroon; Rachaet Rawlings, pale peach; Umpire, pure white, with delicate edge; Triomphe de Pecq, crimson scarlet; Mauve Queen, light mauve; Lord Clyde, red; Mrs. W. Piggott, white; Midnight, very dark.

*Best Eighteen Fancies.*—Lady Paxton, red, tipped with white; Coquette, blush, with maroon stripes; Countess of Shelburne, white, tipped and edged with purple—may be shown in both classes; Elegans, white, striped with purple; Confidence, lilac striped maroon; Gem (Stafford's), crimson, tipped with gold; Leopard, bush dark-striped and spotted; Madame Lemmens-Sherrington, dark purple, tipped with white; Norah Creina, bright orange, tipped with white; Oliver Twist, purple-and-white striped; Queen Mab, pure white, with scarlet edges; Rev. Joshua Dix, blush, striped with dark crimson; Fairy Queen, medium, tinged and shaded with pink; Magpie, black, tipped with white; Zebra, bright scarlet, striped white; Summertide, chocolate, tipped with white, and striped; Starlight, deep scarlet, tipped with white; and Sam Bartlett, deep yellow, tipped with scarlet.

*Best Six Light Fuchsias.*—Bianca Marginata, Fair Oriana, Guiding Star, Minnie Banks, Madame Tietjens, Rose of Castile.

*Best Six Dark Fuchsias.*—Charming, Don Giovanni, Mdle. Trebelli, Puritani, Finsbury Volunteer, and Oberon.—D., Deal.

VEITCH'S EXETER NURSERY.

Your excellent correspondent "D., Deal," in his report of his visit to the establishment of Mr. James Veitch, of Chelsea, does, I think unwittingly, an act of injustice to my friend Mr. R. Veitch in stating that the Exeter establishment, so long carried on under the name of Veitch and Son, has been abandoned, and that the whole energies of the firm are concentrated on the London nursery. It would appear from this statement that no nursery establishment, presided over by any member of this family, exists or will be carried on in Exeter; and if such an idea were to be generally received, it would act injuriously to the interests, not only of Mr. R. Veitch, but to the city of which I am proud to be a citizen. It is true that the late firm has been dissolved, and that Mr. Robert Veitch, for reasons with which I have nothing to do, has decided on not continuing his business at the old nursery. He has, however, taken ground and commenced the formation of one, which will be very much more convenient to Exonians and to visitors to our "ancient and loyal city," being situated at the end of one of our principal streets, and very near to the stations of all the lines of railway. A large portion of the stock has been, or will be, removed from the old establishment to the new nursery, and extensive ranges of houses are in course of erection.

The prospect of the entire breaking-up of the Mount Radford establishment has been a subject of deep regret to our citizens generally; and it is with no small satisfaction that we find the honoured name will still be connected with us. A large amount of the energy, so long synonymous with the name of Veitch, will still be a characteristic of the head of our new nursery, and as with the exceeding liberality, which has so long distinguished the firm, visitors will be admitted with the greatest possible freedom, we cannot but look upon the nearer approach of this nursery to our town-walls as a great and undoubted boon.

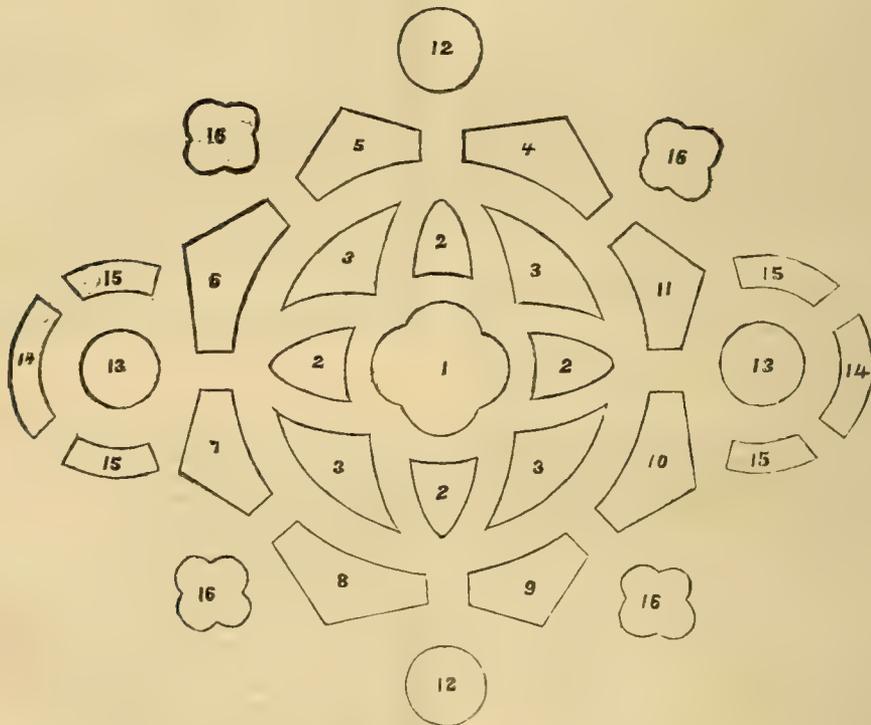

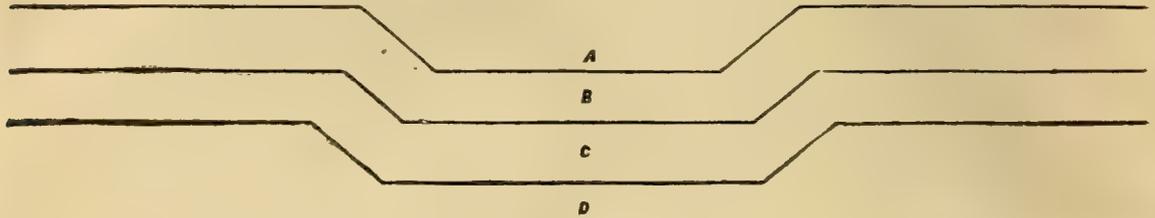

The extensive seed establishment, so long conducted in

our High Street by the late Mr. Veitch, has also come into the possession of Mr. Robert Veitch, and will be carried on by him in connection with the Queen Street Nursery.

I trust "D., Deal," will not think I have stepped out of my way in thus endeavouring to remove a misapprehension

of the actual facts of the case as regards Mr. Veitch of this city. He will see that the unintentional error into which he has been led, will, if it be allowed to remain unnoticed, be likely to injuriously affect the interests of a worthy man, and the esteemed friend of—S. BRYAN FOX, *Exeter*.

### FLOWER-GARDEN PLAN.

a, House. b, Flower-border. c, Flagged Path. d, Grass.

THE border (b) in front of the house in the above plan is to be planted in three lines—Trentham Rose Geranium

next the house; then Lady Plymouth Geranium; and Lobelia Paxtoniana next to the path.

The beds are proposed to be planted as follows:—

1. Purple King Verbena, Cerastium outside.
2. Yellow Calceolaria.
3. Mangles' Variegated Geranium.
4. Trentham Rose Geranium, edged with Golden Chain.
5. Stella Geranium, edged with Golden Chain.
- 6 and 7. Mixed Verbenas, edged with Flower of the Day or Alyssum.
8. Trentham Rose Geranium, edged with Golden Chain.

9. Crystal Palace Scarlet Geranium, edged with Golden Chain.
- 10 and 11. Symmetry Geranium, edged with Alma.
12. Blue Lobelia.
13. Purple Petunias.
14. Golden Chain, Lobelia Paxtoniana, edged with variegated Arabis.
15. Christine Geranium, edged with Arabis.
16. Yellow Calceolaria.

—E. A. L.

[Your garden is very nicely drawn (though by a mistake of the engraver some of the beds are not so exactly balanced as they ought to be), and no doubt will look very pretty planted as you describe. As you have done the most of it on the cross-planting system we would continue this throughout. Thus, instead of making 6 and 7 the same and 10 and 11 the same, we would cross 6 with 10, say Verbenas, and 7 and 11 Symmetry Geranium, edged

with Alma. We would be content with Lobelia Paxtoniana round Golden Chain in 14, and then the Arabis will do nicely round Christine in 15. We presume the ribbon-border is placed close to the house, with the flagged path-way in front of it. This can only be advocated in small places, as borders so placed always conjure up ideas of damp and mouldiness in the walls. Such borders, and pots and boxes there also, remind one of a town garden.]

## WORK FOR THE WEEK.

## KITCHEN GARDEN.

To husband the amount of water that falls to the earth, and prevent the soil from retaining more than is required by the plants cultivated, is of great importance in gardening. This is done by trenching the sound land, trenching and draining tenacious soils, and stirring the surface of both as often as it becomes hardened. This continued hoeing and pulverising the earth among plants has been traced to Jethro Tull; but Tull was no more its author than the writer of this, for he states that he met with these practices amongst cultivators in foreign parts. *Artichokes (Globe)*, prepare a plantation if necessary, by deep trenching and manuring, for if encouraged in this way they will by judicious thinning remain much longer in bearing. Continue the general sowing of main crops according to the state of the soil and the locality. Make small sowings of Borecole, Brussels Sprouts, and Green Savoy; also, full crops of Salsafy, Scorzoneria, Leeks, and Sea-kale. Advancing crops of Peas and Beans should have more earth drawn to them, and some branches of spruce fir or other material should be stuck in on the windward side of the Peas. *Herb-beds*, look over and prick them up, add fresh soil where necessary. Now is also a good time to divide the roots and make fresh plantations. Dress Mint and Tarragon-beds with light decomposed manure. *Potatoes*, plant the main crops. Spinach, Early Horn Carrot, and Stone Turnip should be sown at once on a warm rich border. *Rhubarb*, protect the crowns by straw placed over them. *Sea-kale* in the open ground should be earthed-up to blanch. When the soil is sandy and light it may serve, but should be broken fine before placing it over the crowns, that the heads may not grow crooked. On heavy soils old tan, decayed leaves, or coal ashes are useful substitutes for blanching.

## FRUIT GARDEN.

Premising all pruning, training, &c., of trees and fruit bushes to be now completed, and the ground properly forked over between them, attention should be directed to the Strawberry plantations which have generally suffered severely. The beds should be cleared of weeds, and a dressing of rotten dung spread between the rows; it may afterwards be forked-in very lightly so as not to injure the roots. In doing this spread a little soil up to the crown of the plants, which will assist the growth of the new surface roots. Last season's runners should be gone over, and those made firm in the soil which are thrown up by the action of the frost, after which mulch the surface. Destroy all insects before the trees bud. Clear away all scale, &c., using a wash composed chiefly of clay, water, and sulphur on trees liable to the attacks of insects. Prepare for grafting. Begin with Cherries and Plums, and finish with Pears and Apples. Cut the roots of Red Currants if too gross.

## FLOWER GARDEN.

There are two modes pursued in the formation of grass lawns, the one is by sowing a selection of grasses, choosing those that are of a short and close growth, and the other is by laying down turf. The sowing of grass seeds is done more expeditiously and economically than by laying down turf, and in after years there will be no annoyances in the shape of Daisies, Dandelions, &c. This is a good time for preparing ground for the purpose. Dig it carefully over, pick out all roots of perennial weeds, rake the surface, and bring it to the level required, give a good treading, and then roll it with a heavy roller to bring the ground to a regular and uniform consistency. Having done this, give the ground a slight stir with the rake, sow the seed, and finally roll. The following are the quantities necessary for an acre. For light soil, *Festuca tenuifolia*, two pecks; *Poa pratensis*, two pecks; *Anthoxanthum odoratum*, three pecks; *Lolium perenne tenue*, two pecks; *Agrostis stolonifera*, two pecks; White Dutch Clover, one peck. For very strong heavy soil the mixture should be, *Poa trivialis*, two pecks; *Festuca duriuscula*, two pecks; *F. ovina*, two pecks; *Anthoxanthum odoratum*, two pecks; *Cynosurus cristatus*, two pecks; *Alopecurus pratensis*, two pecks; White Dutch Clover, one peck. Where turf is in a bad state and difficult to mow in summer, let it be top-dressed with some light soil and some Dutch Clover sown upon it. Herbaceous plants should always form a principal feature in gardens

where the family is resident the greater part of the year. To those who have hitherto grown only the usual bedding-out plants and annuals, and who have to wait till midsummer for a display of flowers, we recommend that they procure a selection of the more showy Delphiniums, Campanulas, Phloxes, Dianthus, and other ornamental herbaceous plants, Liliums, &c. For planting among shrubs in borders, and for mixed beds, they are valuable, while the fact of their affording a succession of blooms from early spring nearly to Christmas, ought to insure their more general cultivation, particularly where cut flowers and a continuous show of blossoms are essential. The improvement in habit and colour which is annually taking place in the above and other herbaceous plants is an additional inducement for growing them.

## GREENHOUSE AND CONSERVATORY.

The weather having become milder fire heat may be dispensed with for hardwooded greenhouse plants, unless the night temperature falls below 40°. At this time, however, and for a few weeks, let the necessary watering and cleaning be done sufficiently early in the day for the air of the house to become dry before evening, and then there will be less danger of the plants suffering from a low night temperature, than when they are exposed to it whilst surrounded with a damp atmosphere. Pelargoniums, herbaceous Calceolarias, and plants of similar growth, should be kept in a night temperature of 45°, which may be increased a few degrees, if early bloom is desired; keep them near the glass, and at a sufficient distance apart to admit the light freely to their lower leaves, which otherwise will turn sickly and fall off. The Camellias intended for flowering late in the autumn should now be forced into wood under a temperature of 60° or 65°. Shade if necessary while making their young wood. Climbers beginning to push should after this time be frequently examined to prevent confused growth. Kennedyas, if crowded, should have their shoots thinned. Ipomœas and Thunbergias, being subject to red spider, should be well syringed to prevent that pest gaining ground. Where a large quantity of hardy shrubs is annually forced, either to decorate the drawing-room or conservatory, it is not desirable to pot a fresh stock each season, as a number of deciduous things, such as Roses, Lilacs, Thorns, Honeysuckles, Sweet Briars, &c., may, by proper treatment, be made to bloom for several successive seasons. Select, therefore, the most suitable plants when removed from the house, and give some kind of temporary shelter to gradually harden their foliage. Those cramped for pot-room shift into pots a size larger, using rich turfy loam, and towards the middle of next month plunge them in an open situation in order that the wood may ripen early.

## STOVE.

The Hippeastrums and Amaryllids will now be flowering, and will require rather liberal waterings, and will soon want shifting. See that their leaves are preserved from injury. Pot Cape bulbs as soon as the foliage is becoming strong; use chiefly loam, leaf soil, and silver sand. Water must only be moderately applied to recently-potted plants until they become established; their night temperature should be 65°, with an increase of 10° or 15° on bright days. Maintain a moist atmosphere, and give no quarter to insects of any kind. Make cuttings of the various Begonias for flowering through next November and December.—W. KEANE.

## DOINGS OF THE LAST WEEK.

GENERAL operations chiefly a continuance of those of last and previous weeks. In the kitchen garden turned over the ground intended for Onions, Carrots, &c., but the ground is not mellow enough yet for sowing. Slightly forked among Lettuces that have stood the winter, and scattered some lime and soot among them. Planted out also more Garlic and Shallots, firming them in little drills about 1 inch deep and 12 inches apart, and then throwing some light charred material over them. Run the points of the fork also among young Onions. Turned up ground on banks for Potatoes. Prepared for planting Jerusalem Artichokes, and as soon as possible will clear a piece of ground to be prepared for Asparagus, as we have been forcing rather much of late. Gave Kidney Beans in a pot more room. Prepared beds

chiefly of leaves for more Cucumbers and Melons, and as the plants will not be ready, will first fill the frame with Scarlet and variegated Geraniums, either in pots or on pieces of turf, to be moved as soon as fresh rooted. The beds will then be forked over and a little addition made, as they are not quite high enough to last the season, and we will then turn out the Cucumbers and Melons from pots in which they will be well established but not stunted.

The weather here being still so cold, and the ground wet and cold, moved the Peas sown on turves and placed between the rows of Potatoes into a colder place, but where they could have a little protection. The slight check given to the roots running all through the turves will hasten rather than otherwise the gathering period. No time should be lost in sowing successions in the open air; and if this cold, wet, snowy weather continue it will be advisable to sow Cabbage, Brussels Sprouts, Borecole, and Savoys, in boxes or pots under cover, and then prick out, so as to have them forward for planting.

*Turnips and Carrots.*—Will sow Turnips as soon as the ground is friable, and in a few days will sow a bed with Radishes between, where they can be protected from much frost, as a very little frost early in the season, though it does not seem to hurt the plants much, will ever have a tendency to cause them to run to seed, or make the Turnips hard instead of crisp and juicy, as a young Turnip ought to be, and then it is a delicacy. When wanted crisp and very early much north of London they should have the advantage of glass over them, and plenty of air given back and front. Of course such Turnips could not be sold in competition with those brought from Devonshire and Cornwall, but if people in the north will have delicacies of their own growth they must go to the requisite expense and labour. For such an early crop, if the rows are a foot apart, they may be thinned to not more than from 4 to 6 inches in the row, as the plants will be pulled when of a small size, and the largest first, which will give room to the rest. Gave plenty of air in fine days to Carrots under glass. Will sow a bed of Early Horn out of doors shortly. We seldom sow Carrots for the main crop until April, and then a piece about the middle of June, and the end of July for young crisp Carrots, which, packed in sand, are generally better than those sown late to stand the winter. Small ones from the late sowing are generally hard and stringy.

Will sow Parsnips as soon as possible. They do not mind the cold if they can be sown when the ground is nice and mellow, and friable. For these, Carrots, Scorzonera, &c., the ground should be poor, deeply stirred, and what manure is given should be deposited from 18 to 24 inches from the surface. This will insure straight roots. Those who save seed should now select the best specimens for that purpose. Good varieties often become deteriorated by saving seed from inferior specimens. We have seen fine Cucumbers exhibited, and the seed from the variety have a good sale, and but few specimens produced equal to the originals, because every crooked, deformed fruit that would seed was allowed to do so. The finest kinds of Cabbages and other vegetables often deteriorate, not so much from the age of the variety as from carelessness in saving the seed from inferior plants. Seedsmen should look to this, or gardeners at much inconvenience will have to try and save their own seed. Nothing looks better than a quarter of Cabbage with the plants all uniform and not a "rogue" among them; but how often does it happen that the rogues occupy a more than desirable place in the quarter. As the ground is still rather wet will plant another piece of Potatoes where protection can be given them, with Radishes, &c., between the rows.

#### FRUIT GARDEN.

Pruned trees when we could, and, a severe frost having threatened, stuck some handfuls of rough hay and some branches among the shoots of Apricots, though, as it turned out, the frost was not severe enough to injure the blossoms, swelling fast. Moved Strawberry pots in bloom to the best positions for light and air. Provided the temperature is not too high, we do not consider the air question so important until the truss shows. Last year a great enthusiast took us to try and explain why his Strawberry plants would not show bloom. They had been brought from out of doors into a close house of from 70° to 75°. If they had been a little close for a time at 50°, it would have done little harm,

though it is safest, when practicable, to give air at all times. Placed pots of this fruit in every suitable place in vineries, Peach-house, &c., where heat, and light, and air could be given them, bringing the fresh plants in every instance from frames where there was just a little heat, so that much of a check should not be given; for a sudden change from cold to heat is often as prejudicial as a sudden change from heat to cold. In a sunny hour, waved a long thin board, like a fan, over the Peach trees in bloom. In these slightly frosty nights, left all the air possible on the orchard-houses, alike to keep the trees back, and to give any insects that may be left the benefit of the cold. We have not yet been able to set out our second house, and we find that we are behind in many things, owing to extra work out of doors, planting, &c., and the weather, which hindered such work considerably. There must be sharp work to bring up the leeway. In vinery thinned and regulated shoots, and tied down, to keep bunches from being too close to the glass. Cut the remaining fruit in late house; pruned Vines, washed the house and Vines, and painted them. We generally used to tie them along the front of the house, but, to save time in untying and tying up again, after washing them, or painting them with clay, sulphur, soot, and softsoap, we suspended them from 24 to 30 inches from the glass. Having watered the back border with drainings from the farmyard, reduced in strength with warm water, to make it from 70° to 80°, we fresh-surfaced it with soil and a little soot, and old powdered lime, and filed a small stage in the centre with Pelargoniums, and the shelves against the back wall, and the floor of the house, with bedding plants. Here it is but right that we should record

*A misadventure from using dry soil, soot, and even old lime,* under such circumstances. A little condung had been placed on the border before watering, the border being very dry, as we had no water to give it in the autumn, and did not wish to have the house damp in winter. After the watering, and the drying of the surface, and adding a little fresh soil, but not so dry as we wished, we applied the above dry surfacing thinly, for the boxes and pots to stand upon, and as, for the sake of the plants in them we wished the air to be dry about them. Nothing suffered except some nice boxes of *Calceolaria amplexicaulis*, which we found did not quite like the rough treatment we gave to other *Calceolarias* in a cold pit, and which, therefore, we kept, where it was possible to give a little fire heat—in this late vinery, indeed. In clearing the house they were removed to an earth-pit, and protected for a couple of nights; but as we had several times had them nibbled by mice in such circumstances, we returned them into the house, placing the boxes on the floor. In the morning many of the leaves looked as if they had been sprinkled with hot water, or scalded, and we expect that some of the plants will die. The ammonia from the manure water, and the soot together, had been too much for them. The house had a rather strong smell in the morning. Most likely, too, the little lime, which we thought as mild as chalk, and used for its dryness, had some acidity left, and probably, also, some of it was still quick. Among the hundreds, or rather thousands, of other plants in the house, nothing seemed to suffer in the least except these *Calceolarias*. Even a few new sorts of other *Calceolarias* suffered little or nothing. It is right to add that the *Amplexicaulis Calceolarias*, from standing a long way from the glass, and being a little shaded, were a little drawn and tender, in fact we intended topping them for cuttings. We mention the circumstance as a caution, to be careful of the application of soot in confined places. The soot was very fresh and good. We have not a doubt that the injury was entirely owing to the ammonia given off. One of our young men states that he once saw a large frame of nice plants of *Perilla* destroyed in a night from fresh soot having been strewn slightly over the mild sweet hotbed in which they were growing. It is well known that the fumes from manure water in evaporating pans, and the fumes of sulphur from hot-water pipes, that would not incommode Vines and Peaches, would soon curl up the fronds of the more tender Ferns.

#### ORNAMENTAL DEPARTMENT.

Did little out of doors except routine. Will set to work among herbaceous plants and shrubs as soon as possible. Roses, prune as stated last week. Lately we noticed the *layering and pegging-down Moss and Provence Roses*. This,

more than a generation ago, used to be done with fine effect on the terraces at Valleyfield, under the management of the late Mr. Stewart, who along with such worthies as the Messrs. Beattie of Scone, McDonald of Dalkeith, McNab of Edinburgh, Bishop of Methven, &c., constituted the aristocracy of Scottish gardeners in our boyhood; when Donald Beaton studied at Perth when other men slept, and improved himself under Barnet with the greater advantages for self-culture which Edinburgh afforded. These Roses were richly manured every year; the shoots were thinned-out in summer, leaving from three to five or more of the strongest to a plant. These would generally grow from 3 to 5 feet, or more in length. In autumn the old shoots were cut clean out, the ground manured and forked over, the points of these long shoots nipped off, and then pegged-down pretty close to the ground, and almost every bud threw up next season a stubby short flowering-shoot, making almost a carpet of splendid Roses. We have never seen the system so thoroughly carried out since, though it has frequently been practised by ourselves and others. These carpets of Roses never cross our memory without bringing to our mind the slim form of the good, kind-hearted, clever old man who generally did the pruning and the pegging with a neatness and artistic finish that the young blue aprons could scarcely hope to imitate. With all his neat handedness and goodness of heart our old friend had a dash of the eccentric, which seemed to have prevented him taking a suitable social position. What was rather uncommon then, in his very young days he had gone to London, no doubt to obtain a share of the Scotch good things that went there; but he did not succeed, came back, and ended his days at Valleyfield as a garden labourer. This story of Roses will not be without its use if it lead our young brethren, who often must live with but little society, studiously to refrain from cultivating an eccentricity of manner, address, or action, as this eccentricity has caused the wreck of the social standing of many a clever man, besides good, happy Robert Horn.

Gave plenty of air when the weather would permit to Calceolarias in cold pit to fit them for going out of doors under the protection of mats, branches, &c. Protected earth-beds from rains that the soil may be dry for Geraniums. Gave manure water to Cinerarias, Primroses, Camellias, Azaleas, &c., the latter weak. Looked to forced flowers, bulbs, &c. Proceeded with potting all kinds of plants; the useful in the shape of Strawberries contending for space with flowering plants and bedding plants. Examined Caladiums that were fresh potted and placed on a slight hotbed, and find they will soon want fresh potting. If roots are well encouraged now, the leaves will be sure to come fine afterwards. Started Begonias, Gesneras, Achimenes, &c., below Vines, and when fairly in leaf, or showing leaf, will fresh pot. Proceeded with cuttings, and sowing tender and half-tender annuals, in the way frequently advised, but which we suppose we must soon repeat if we would please some of our readers, who tell us that we write as if all were readers from the beginning, and also that we have neglected window gardening of late. In the meantime we would say to all intended cultivators of the *Perilla* and *Amaranthus melancholicus ruber*: Sow the seeds and place in a mild sweet hotbed before the middle or the 25th of this month, and harden-off as soon as possible. If larger plants and stunted, they will not thrive so well as younger plants not stunted. The *Amaranthus* makes a fine shade with the *Perilla*, and few plants soften down so well the bright creamy yellow of the *Calceolaria amplexicaulis*. Our place is rather too cold and exposed for it. If seedling Lobelias, &c., are up, be careful to prick off before they be too close together and damp off.

Other plants much the same as in previous weeks. We would particularly wish the growers of fine Pelargoniums to be careful to give air so early in the morning that the leaves may all be dry before the sun strikes them, and also that the plants will do better if the pots are set on boards, than on any other substance; ashes, earth, sand, &c., being the worst.—R. F.

TRADE CATALOGUES RECEIVED.

London Seed Company, 68, Welbeck Street, Cavendish Square, London.—General Price Current of Farm Seeds.

J. C. Wheeler & Son, Gloucester.—Wheeler's Little Book on Grasses, and Priced List of Farm Seeds.  
William Paul, Waltham Cross.—Spring Catalogue of New Roses, Geraniums, Hollyhocks, Dahlias, &c.

COVENT GARDEN MARKET.—MARCH 11.

The supply of Greens and other out-door produce continues rather short, and the quotations of last week are fully maintained. Apples are still very plentiful, other fruit sufficient for the demand. Forced Strawberries are selling at 3s. 6d. per ounce; and some new Grapes may also be had. Of the old there is still a good supply. Continental importations are well kept up, and comprise the same articles as mentioned in previous reports. Of Potatoes there is a heavy stock.

TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

LILIUM LANCEFOLIUM RUBRUM CULTURE (*G. Wagner*).—A six or seven inch pot will do for a strong bulb of this Liliium. Drain the pot well, and on that place some rough peat and loam, filling the pot about half full. On this set the bulbs, and just cover all except the point, and then set the pots under your stage on the floor, and give little water until the stem begins to move; then bring them into the light, and earth up as the stem grows. After the end of May a sheltered place out of doors will suit them as well as the greenhouse or cold pit. When growing freely they require plenty of water.

SEEDS FROM NEW ZEALAND (*P. C. A.*).—*Pittosporum tenuifolium* is an evergreen greenhouse shrub, growing about 3 or 4 feet high, having, if we remember aright, yellowish white flowers in April and May. It does well in a compost of sandy peat two-thirds, and sandy loam one-third, with a free admixture of silver sand. *Eucalyptus grandiflora* is a deciduous or sub-evergreen shrub, hardy in some situations against walls with south or south-west aspects, but is at the best a half-hardy plant requiring protection in winter. It has yellowish flowers in May and June, and attains a height of 6, 10, and occasionally 12 feet. It requires a sandy peat soil. *Podocarpus ferruginea* much resembles a Yew, with much wider leaves. It is a half-hardy tree. *Eucalyptus globulus* is an evergreen tree, attaining a height of 100 or more feet, and is not hardy, nor are the others named, all being half-hardy plants, and doing best in a cool greenhouse, or a house from which frost is barely excluded. We do not know the others sufficiently to describe them. The seeds of all would be best steeped in water at 100° for twenty-four hours before sowing, which may be done at once in a compost of sandy peat and loam. Cover the seeds lightly, no deeper than their own diameter, place the pots in a little bottom heat, and when the seedlings are fairly up gradually harden off and grow on in a greenhouse, potting them singly into small pots when sufficiently large to handle.

**ALLAMANDA GRANDIFLORA AND IMPATIENS HOOKERIANA CULTURE** (*A Darford Reader*).—The Allamanda had better be potted at once, giving it a liberal shift, say from an 8-inch into a 12-inch pot, draining the pot well. Impatiens Hookeriana should be potted, when it commences to grow, in a compost of turfy peat, loam, and leaf mould, in equal parts, with a free admixture of silver sand. It should be grown in a moist atmosphere, be kept near the glass, and never have a sodden and sour soil about it. Whilst it is growing the soil should be kept well supplied with water, and good drainage should be provided; but when it has bloomed it should not be so freely watered, and water should be gradually withheld until the plant goes to rest, when the soil should be kept moderately dry until growth recommences. It is a stove plant.

**DATURA ARBorea PRUNING** (*M. F.*).—This fine old plant should have the shoots well cut in, and if the wood was well ripened they may be cut to two eyes, always pruning so as to secure a well-shaped plant.

**FERNERY ADJOINING DWELLING-HOUSE** (*M. I. P.*).—Judging from your plan, we think your proposed situation for a fernery for half-hardy Ferns would answer admirably; but instead of having it 8 feet square we would carry it 4 feet towards the garden, or to the end of the house in that direction. The circle, we presume, is intended to show the position of a pipe to conduct the water from the roof, which we would carry into a cistern within the house, so as to have water always at hand ready aired to water the house. In the direction of the door from the house it might be extended 4 feet more, making it 16 feet long, and by adding 2 feet to the width there would be room for a walk 4 feet wide for access to the garden. We would have the walls of brick or stone, to correspond with the house, no front lights, a lean-to roof, and glass ends. Two lights or windows, one at each end at the highest point, and hung in the middle, would be ample ventilation, and there would be a saving in having the roof without moveable lights. The front might consist of rock stones as high as the wall, and extending into the house a distance of 3 feet, and with a little taste in the formation this would be a pleasing feature. The openings between the stones being filled with a suitable soil, would hold more and a greater variety of Ferns than four times the space were it shelved or staged and the plants grown in pots; the rockwork would be, besides, a much more natural feature. Opposite the drawing-room window you could introduce a dropping well, small cascade having water dripping over the stones, or a fountain with a basin for gold fish. This would be an admirable place for the less hardy and more desirable kinds of the British and hardy exotic Ferns. The rockery would extend along the front and both ends of the house, allowing for the door at one end as proposed. A three-foot walk next this will leave a space of 4 feet at back to dispose of. Were it not contiguous to the house we should have no hesitation in forming a rockery there to correspond with that in front, and this would look best though it might render the wall damp. We should therefore advise you to have a stage there, and grow the plants in pots, taking the hot-water pipes beneath it. If the space at back were formed into a rockery we would not heat it at all for half-hardy Ferns, there being many of the British and hardy exotic Ferns that would do well in it. With hot-water pipes under the stage you could grow many greenhouse Ferns on the stage at back, and the hardier ones in front planted in the rockery. Provided Ferns have light they do not need sun, and your house would require no shading in summer—in fact it is just the place for a fernery, and is calculated to give twice the gratification of a Warden case, which, however, is very well when there is no room for anything larger.

**MANURING FOR POTATOES** (*A Beginner*).—Give the ground, previously to digging, a heavy soaking with the contents of your cess-pool; and if the plants during their early growth seem weakly, pour another good soaking between the rows, and repeat it after a fortnight if apparently needed. In a poor soil we should prefer this treatment to a heavy application of stable manure.

**VINES IN POTS BLEEDING** (*W. S.*).—You have pruned your Vines after they had commenced growing. If not started much move the pots to a colder place to arrest the flow of the sap, then take a hot iron and scorch the points of the shoots, and then dab them with red or white lead as soon as it is done. A little oozing will do no harm, but a free flowing will weaken the Vines. As soon as the leaves break they will take up all the sap.

**FLOWER-BEDS** (*A Subscriber to the Journal*).—We think your design will look very well; but as your four beds in the centre are yellow Calceolaria, and the four beds next them are Lobelia, edged with Cerastium, we would be inclined to continue the same system with the four outside or larger beds—that is, we would make each purple, white, and scarlet; or two might be purple, &c., and the cross-balancing two mulberry, white, and scarlet. These would look very nice, either in rows of colour, or even if the colours were mixed. Keeping the rows distinct in these large beds would look most artistic. If wide enough for five rows we would place purple in the middle, white round it, and scarlet outside.

**WEDDING BOUQUETS** (*A Constant Reader*).—In that for the bride there should be little but white, the exception being a little dressing of Forget-me-not, Lobelia, &c. At this season white Camellias, Epacris, Lily of the Valley, white Primroses, Deutzias, &c., will be in demand, and of course will vary according to the season. For br' demaids, &c., the colour is not so particular, but white should form a large portion of their bouquets. We may before long refer to bouquet-making, but a glance at the shops in Covent Garden Market would tell you more than a long article. Our coadjutor Mr. Robson has much experience in this matter, and may be induced to help.

**BULBS DONE FLOWERING** (*Thom*).—You had better keep the Hyacinths, Tulips, and Narcissus as long in the greenhouse after flowering as you can so as to encourage the foliage, then place them for two or three weeks in your cold house, and then plant out of doors, and shade and protect the foliage a little at first. The Tulips if so treated will bloom next season, and many of the Narcissus will force, but the Hyacinths would be better of a season in a flower-bed before being forced again. Everything depends on giving no check to the foliage until it naturally turns yellow. Your Tuberoses would have done better if treated as Hyacinths. It was wrong to keep the soil so dry. If the pots had been covered over the dryness would have been prevented. If you could plunge the pots in a very slight hotbed, say about 65° to 70°, and cover the bulbs 2 or 3 inches deep, we have no doubt the bulbs would start strong if they are in good condition. We should be glad to have an account of your gas apparatus. We agree with you that for an apparatus so heated copper or tin pipes are better than cast iron, but the latter we believe to be the most economical as to lasting, whilst the copper, &c., are the easier heated, but do not keep the heat so long.

**BLAZE OF SCARLET** (*J. N.*).—Good old plants of Tom Thumb Geranium will not be surpassed by anything else for a blaze of scarlet in your window.

**STRIKING CUTTINGS OF MRS. POLLOCK GERANIUM** (*E. T., Amateur, Wilts*).—Mrs. Pollock, like most Geraniums, may be raised from leaves with the eye attached, or in other words, from eyes. Take the cuttings from the plant, and cut transversely below the lowest leaf, and then, placing the knife about half an inch above the eye, cut the stalk in a sloping direction towards the base of the shoot. The leaf is not removed, and the eyes having a flower-stalk opposite the leaf are of no value for the purpose, as there invariably is no eye at the base of the leaf. The large leaves only are available for forming leaf cuttings. The extremities of the shoots should be inserted, like ordinary cuttings, with one joint in the soil, and the growing point above. There is this advantage, in propagating Geraniums from leaves, that the lowest leaves, usually cut away in preparing the cutting for insertion in the soil, may be converted into leaf cuttings. The cuttings being made as described, drain the cutting pots effectually, and fill them to within half an inch of the rim with sandy loam, leaf mould, and silver sand in equal parts. A little silver sand is then placed in the pot, a quarter of an inch or so, and the cuttings inserted about half an inch deep, each leaf being tied to a small stick, with matting round the footstalk, to maintain it in an erect position. A slight watering is then given, and the pots plunged in a bottom heat of 75°, a top heat of 60° or 70° being afforded. The frame having a moist atmosphere, there is little necessity to water; none should be given so long as the soil remains moist, and the less water needed the better, as the great evil is the liability of the footstalk of the leaf to rot, and the consequent destruction of the eye before a callus is formed. Shade is given for a few days, until the leaves are able to bear the sun; and in this position they remain until the shoot from the eye appears, when they are gradually hardened-off, and finally potted-off singly in small pots.

**GERANIUMS—VERBENAS** (*Yorkshire*).—Best two white *Variogated Bedding Geraniums*: Flower of the Day, Queen of Queens. Best golden ditto: Mrs. Pollock, Mrs. Benyon. *Bedding Geraniums*: Clipper, Miriam, Editor, Lord of the Isles, Herald of Spring. *Nosegay*: Cybister, Stella, Oasian Fifteen, good *Verbenas*: Géant des Batailles, Foxhunter, Madame Magras, Fantastic, Admiral Mitford, Faust, Beauty, General Simpson, Lord Rattran, Mrs. Holford, Madame Lefebvre, Nemesis, L'Avenir de Ballent, Peep o' Day, Ruby King.

**POTTING ROSE CUTTINGS** (*Felixstone*).—The cuttings inserted in a frame last July, which you wish to remove to your new garden, had better be potted now, and returned to the frame, keeping close for a short time, and then harden-off by the time you remove. They will remove much more safely than were they taken up and planted in the new garden at once, planting them out in May, with the ball entire.

**SIZE OF POTS AT FLOWER SHOWS** (*A Subscriber*).—There is no settled rule among horticultural societies as to the size of pots in which plants shall be exhibited. It would generally militate at first against the success of an exhibition if the size of pots all over were to be individually of so many inches in diameter; but if the size of pots were restricted to 8 inches in the case of some things, as Cinerarias, Calceolarias, Geraniums, &c., it would be a better test of the relative skill of the exhibitors, and also render it easier for the judges to decide as to the merits. We recollect being a little in doubt as to Cinerarias in seven-inch pots, and great bushes in 14-inch pots, but on moving the moss garnishing we found three plants in the large pots, so that the exhibitor showed eighteen instead of six plants. In a small country flower show it would not be wise to restrict too much, but the majority of the members must decide. If you want more heat add to the flow-pipe by all means. We have seen four or five pipes placed horizontally as flows and one to act as a return. The flows will be about the same temperature.

**NETS OVER WALL-FRUIT TREES** (*A Subscriber, Ballinasloe*).—Keep the nets over the trees until all danger of frost is past. If your trees are vigorous they need no liquid, or any other manure.

**PUDDLING WITH DRY CLAY** (*N.*).—Our own experience coincides with the advice given by "UPWARDS AND ONWARDS," second column, page 168, as to ramming hard dry clay outside the wall of a tank. For manure water or sewage water only such ramming will often be effectual for holding water without any other wall whatever—at least so long as it is covered by water. Being placed inside, or fronted by a wall of 4½ inches built with cement, the dry clay, but wet enough to be rammed, would answer for such a purpose much better than wet puddling.

**STOPPING CRACKS IN CEMENT** (*Idem*).—In clay grounds where the tanks are large, though built in the usual manner with brick and cement, extra wetness and extra dryness in the surrounding soil will affect the walls at times and cause fissures and cracks, through which the water will escape. In such cases the cracks are generally too small to admit enough of cement to make all sound, but if the opening is chipped on both sides, say for an inch or more of an opening, and the sides are left rough, and these are well wetted before the application of the cement, we never found any difficulty in the matter whatever; and so far our experience favours that of the writer, and is opposed to the opinion of the plasterer. A small opening, say of an eighth or a quarter of an inch, cannot be stopped so efficiently. The mode of connecting the pipes by means of a one-inch lead pipe, page 177, is merely given as a matter of economy. It would be better if all were uniform; but the small connecting-pipes do little to arrest circulation. We have heated large tanks by taking a one-inch lead pipe from a four-inch flow-pipe, even though the inch-pipe was regulated by a common beer tap, to let the heat in when desirable.

**FLOWER-GARDEN PLAN** (*S. S. S.*).—The design is so pretty that we cannot well improve it, and of the planting we may say the same. To make the plan complete, however, the two ends should be chain-bordered, as well as the sides, if the position will admit of it, and then an opening could be left at each end in the centre. The little circles might also be planted with small upright evergreen shrubs, &c. No fault can be found with the arrangement of each of the four scrolls, but it is difficult to please in dividing such scrolls into separate colours. For another season it might be well to adopt a simpler arrangement, and so to plant the centre with scarlets and white, and the chain-borders with the same, that the four scrolls might be crossed with pairs of yellow and pairs of purple. This would give greater ease, repose, massiveness, and simplicity, but not the variety that you will gain by your mode of planting.

**NAMES OF FRUIT** (*R. H. A.*).—Your Apple is Rymcr. (*Thamo Park*).—1, Unknown; be good enough to send us two or three more specimens;

3, Autumn Pearmain; 4, Herefordshire Pearmain; 5, Tulip; 6, Sweeny Nonpareil.

NAMES OF PLANTS (*Clericus*).—1, Lastrea dilatata; 2, Lastrea Filix-mas; 3, Too young, perhaps Hypolepis tenuifolia; 4, Blechnum occidentale; 5, Peris serrulata; 6, Polystichum angulare proliferum; 7, Gymnogramma

ochracea; 8, Doodia caudata; 9, Lastrea Filix-mas, young; 10, 11, Selaginellas, but impossible to name from such scraps; 12, Pteris hastata macrophylla. Your misnamed plant is Aspidistra lurida variegata. (*L. S. D.*)—1, Apparently a sterile frond of Lomaria Patersoni; 2 and 4, Asplenium viride; 3, Selaginella rubricaulis; 5, Asplenium flabellatum; 6, Asplenium marinum.

METEOROLOGICAL OBSERVATIONS in the suburbs of London for the week ending March 11th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE LAWS OF NATURE

IN RELATION TO POULTRY KEEPING FROM A COMMERCIAL POINT OF VIEW.

(Continued from page 183.)

3. Are the eggs not affected by the heat whilst being packed?—Although the jars are placed in boiling water the internal temperature never exceeds blood heat, and as eggs are not affected by that temperature, which is the same as that at which they come from the hen, it becomes only necessary to avoid packing the eggs against the jars without a lining of cocoa-nut refuse, which ought to be perfectly dry and used warm for packing.

4. How can you tell when a jar is air-tight?—To ascertain whether a jar is air-tight when empty is easy enough; it is merely necessary to fill the jar with boiling water, and when thoroughly warm to empty out the water, then close the jar quickly with the air-tight cover, and place it inverted in a tub of cold water. The air in the jar, thus rarified, will be condensed by the cold water. If not perfectly air-tight some water will find its way into the jar, which can be ascertained by opening the latter a few hours afterwards. This test, however simple, cannot be applied to filled jars as it would be necessary to open the jars again. Now, this very same question I put to several pickling firms, and obtained the unsatisfactory reply that they consider when jars are air-tight when empty they will be equally so when filled. This, however, cannot be depended on as the cover may fit in one place and not in another, or it may not be screwed down so much at one time as another.

5. Can you at any period ascertain whether the jars continue air-tight?

6. Which are the best air-tight jars, glass or stoneware?

These two questions I will endeavour to answer under one head, and to prevent my being considered to advocate one principle more than another from an interested motive, I must inform my correspondents that to most scientific men and poultry-breeders it is well-known that egg preserving has formed the study of some of the most eminent chemists in Europe, and that until I published, through THE JOURNAL OF HORTICULTURE, my simple and yet the only truly effective mode of preserving eggs for any length of time no satisfactory means had been discovered. The intense interest this discovery has created throughout England has induced me to ascertain which of the professed air-tight jars are really so, in order that the public may not lose their confidence in so important a discovery on account of the jars not being to be depended on. Through the kindness of an eminent firm in the pickling trade I have been enabled to make experiments with the various so-called air-tight jars, few of which really were so, and all without exception objectionable on account of their construction. Then there came another important consideration: how can it be ascertained, when the jars are filled, whether they are air-tight, and how long they will remain so?

This, of course, was a perfect impossibility with the jars as at present manufactured.

These important deficiencies in air-tight jars for preserving eggs have led me to invent a jar purposely for egg preserving, and which jar is not only perfectly air-tight, but it will show at a glance whether it is so, and how long it remains so, by means of its patent pneumatic self-indicating cap. I have every reason to believe that these jars will remain air-tight for any number of years, and that the eggs preserved in them will remain as fresh as on the day they were laid, and fit for hatching and the breakfast table. Now, although such jars can also be made of glass, which would have the advantage of showing the eggs, yet when it is considered that glass is liable to crack when put into boiling water, particularly during cold weather, it is my opinion that glazed stoneware is preferable.—G. K. GYVELIN, C.E.

POULTRY JUDGES.

I READ now and then, in your paper and elsewhere, of a certain Poultry Club which is to dominate over local associations in much the same way as monarchy did over feudal potentates, and the change is, doubtless, a good one in principle.

At the same time I do not clearly gather the scope of the Club's proposed operations. Apart from the establishment of a standard of excellence (which the Club hopes to settle hereafter, and which I hope it may, and that judiciously, so as to obtain general assent), the great point made seems to be the putting down of "dealer judges," or, as a semi-official article has said, "persons who sell birds." Now, in horticultural shows, the amateur and nurseryman's classes are very different; but in the matter of poultry the amateur who does not sell off his surplus stock whenever an adequate price is forthcoming, is, I imagine, a rare variety of the fancier species. Now, if the habit of selling birds infallibly perverts the moral sense, I doubt whether entire rectitude be consistent with even occasional bargains. Why not disqualify at once all who keep birds the value of which would be affected by competition, including, of course, all whose relatives or friends may be in that predicament? Living in an out-of-the-way locality, I know nothing about the secret history of the matter; but it seems to me invidious to throw reproach on a class, and, if as I suppose, it be a very limited class, rather an ignoble object to put in the foreground of the programme.

There is no royal road to the selection of judges. Character—that is, recognised skill and integrity—is the growth of experience and publicity. There are different kinds of people—fast and slow, bold and timid, vulgar and "genteel." Classification is an excellent aid to natural history, but none at all in choosing poultry judges, any more than the colour of their hair.

As to the wisdom of special arrangements to prevent judges' acquaintance with the ownership of the pens, any mark or indication found on a bird at once, as I am told, disqualifies it; and it is proposed to mark the pens for judging apart from the numbers in the catalogue, which

might be communicated by a knavish exhibitor to give a cue to a knavish judge. But surely the parties in collusion, if such things be, would be muffs also not to evade any such precaution. It is not necessary to know the number, for a man may know the birds. Is not broad daylight the best preventive to cheating—viz., publicity and free discussion among the poultry-loving public? and does not the reliance on secrecy lead to a kind of countermining—a trial of skill between the party that insists on keeping a secret and the one that is so much the more eager to find it out?—T. T.

### EXTRA PRIZES FOR BUFF COCHIN-CHINAS. (CIRCULAR.)

THE additional prizes of silver cups to Buff Cochins at the late Birmingham Shows having proved of such importance to the breeders of this variety of birds as to make it most essential that these extra prizes should be continued, in fact extended, I have consulted some of the most influential breeders upon this subject, all of whom have promised to subscribe £2 each; and I may add that in consulting Captain Heaton he most liberally promised that if £20 could be collected he would give £5 himself to make the amount £25, to be divided as follows:—viz., £5 silver cup to each old and young birds, £5 cup for the best single cock, £5 cup for the best pair of hens, and a £5 cup for the best pair of pullets. Thus divided, all breeders would have a good chance of obtaining a most desirable honour; and to enable this to be done the amount must be subscribed before the Birmingham prize-list is published, so that the extra prizes may appear in the same, and gain publicity in the catalogue at the time of the Show—a matter so important, and which could not be done last year in consequence of the amount not being subscribed until after the prize-lists were published. It is proposed that these prizes shall be given for general competition, and you being a breeder and exhibitor of Buff Cochins will, I am sure, estimate the importance of these extra prizes, and forward your subscription at once, that the necessary amount may be made good. Mr. Lythall, the Secretary of the Show, has kindly offered to receive all subscriptions and provide cups, which will be presented to the successful exhibitor on the first day of the Show.

Your prompt attention will oblige yours, most respectfully,  
HENRY TOMLINSON, Balsall Heath Road, Birmingham.

[It will be evident to our readers, from the circular issued by Mr. Tomlinson, that those amateurs who feel an interest in breeding Cochins are busily exerting themselves to offer some additional valuable prizes to be competed for in conjunction with those appointed by the Birmingham Committee at the Show to be held in Bingley Hall next December.

When it is borne in mind these "five extra silver cups for Cochins" are to be allotted to a variety of domestic poultry, perhaps the most popular and useful of any, we cannot doubt but that the amount required will be readily obtained, particularly as we understand more than half the money requisite is even already in hand. It will, however, be necessary for subscribers to give notice of their intention to become aiders of this movement as speedily as possible, for by so doing it will allow of a list of the additional premiums appearing in the forthcoming Birmingham prize schedule to be issued in about a month hence; and it will also make it certain that the names of those parties who may eventually prove successful will be printed in the Birmingham catalogue.]

### SCHEDULES OF POULTRY SHOWS.

SURELY your correspondent "Y. B. A. Z." wrote the post-script to his article without reflection. If I received a catalogue or list of prizes of the Bradford Show, which contained no prizes for Brahmans, and the Committee afterwards resolved to make a class for those birds and to offer prizes for them, ought not the Secretary at once to have forwarded me an amended catalogue? The catalogue was sent to me without any application from me; and, as such, the Secretary of a poultry show keeps, or ought to keep, the names of those to whom prize lists have been forwarded, and he ought to have sent an amended one to all who had received the first.

At all events, some Brahma breeders had amended catalogues sent them, otherwise there would have been no exhibition of that class, and no prizes awarded. The effect of sending them only to a few instead of to all certainly limited the competition and leaves it open to remark. Poultry Committees and Secretaries should be like Cæsar's wife, not only without-fault, but above suspicion.—J. WRIGHT, Church Street, Woodbridge, Suffolk.

### POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.

"NEMO," the defender of "C. S. J.," has my best thanks for his kindly lecture as to what is required to establish the success of anything now-a-days. I do not find fault with his opinion as regards the profits poultry breeding will yield, and in the absence of any actual statistics of my system on a large scale, I can only reiterate what I stated in my reply to "C. S. J." There are, however, a few assertions with which I beg to differ, even with "NEMO."

1st. Were it not for sanguine minds few improvements would ever be carried out, and were even the minimum profits given there would still be found many persons who would with just as good reasoning reduce it below zero.

2nd. The artificial hatching can be entirely dispensed with in my system, as for every 1000 hens, I can rear at least 10,000 chickens, and under any circumstances it will only be resorted to to hatch chickens when hens have ceased to be broody. As to whether my system of artificial hatching is superior to that of Cantelo or any other, I may state that I do not claim any originality, but rest the success only on the well-known law of a uniform temperature at which there is not the slightest difficulty to hatch chickens, and this uniform heat can be maintained either by manual or mechanical means, which are well known to engineers, and which will be described in some subsequent Number of this Journal, under the laws of nature in relation to poultry-keeping. The failure of Cantelo, and others, cannot be ascribed to the hatching, but solely to the rearing of the chickens. Now, this is my system, and on it I rest the success of poultry-breeding, and though I do not intend to rely on artificial hatching, yet I shall entirely depend on artificially rearing all the chickens, whether hatched by a hen or by an apparatus.

3rd. My system of breeding poultry and its profits can no more be judged by the present mode than railway travelling when first projected could from the old stage coaches. For its success it will require a staff of servants, and a subdivision of labour, then a good disciplinarian as superintendent, and the whole will form a piece of mechanism which will work with the greatest precision, and afford such statistics as will surprise sceptics. To carry this out is a mere matter of money and will, whether by a private individual, or a public company; but the idea of an association of working partners to attend to fowls, is simply ridiculous, and I doubt whether, if they could be found, they would long remain a united family.

4th. If "NEMO" will take the trouble to read the article on natural hatching, No. 198, he will find that I advocate natural hatching and artificial rearing. Has it ever occurred to him in estimating the annual profit of a hen, to charge to her credit the hatching of one or two broods, which surely is more valuable than the number of eggs she could lay in twenty-one days?—GEO. K. GEVELIN, C.E.

THE IRISH EGG TRADE.—At the annual *soirée* of the butter and egg merchants of Glasgow, Mr. Patrick Meehan, who occupied the chair, mentioned the following particulars regarding the import of eggs from Ireland into Glasgow.

"That the butter and egg trade is becoming of considerable importance there can be no question. I will only refer to one item in it. Both Derry companies have run six steamers weekly, carrying each an average of 100 boxes of eggs; and I think we may safely allow 100 boxes from Cork, Dublin, and Belfast—in all, 700 boxes per week, or 36,400 per year. The average price per box is £8, so that the annual value of the eggs imported into this city alone is little short of £300,000."

**GOLD AND SILVER PHEASANTS.**

We shall feel obliged if our readers and contributors will inform us when the earliest Golden and Silver Pheasant's eggs are laid. It will also be giving much real pleasure if they will note the advent of our birds of passage and our warblers. Many of us who, perforce, are obliged to live in town or towns, have our reminiscences. We recollect the note; we know the spot where we used to see the first Swallow; to hear the first Nightingale; and the "*Mal du pays*," is sufficiently strong upon us, to enable us to enter fully into the feelings of the emigrants in Australia, who made room for each other round the door of a house in Melbourne where the first Skylark was to be heard.

**DOE RABBITS NEGLECTING THEIR YOUNG.**

I KEEP a variety of doe rabbits, and after they had many young ones, all of which lived and did well, I was greatly surprised to find that the next time they had litters the young ones were scattered all over the hutches and left to die. As this was done by all of them I concluded that it was owing to the way in which they were fed, and so it proved. I think if "J. N." (your correspondent) feeds them in the following manner he will not be disappointed:—Oats and bran twice a-day, a little more than they can eat at the time, and cabbage leaves. Offer the does water, and when they have young ones give in addition a spoonful of fine middlings mixed with pea chaff and water.—S. B.

**SWARMING VERSUS STORIFYING.**

WHEN your correspondent "J. E. B." in No. 192, communicated his experience "that hives permitted to swarm, if forward, will yield a larger harvest of honey than they would do if kept on the conservative principle," I expressed in No. 196, the opinion that either the worn-out condition of the queens of his storified hives, or something radically wrong with their management, had induced this invidious comparison.

Subsequently (in No. 200) "J. E. B." was good enough to favour us with the history and mode of treatment adopted with his three storified hives A, B, and C, at the same time quoting Dzierzon in support of his opinion. If the system of management of your correspondent be a counterpart of that recommended by his celebrated continental authority, I, too, must subscribe to the doctrine that the subdivision of hives augments the honey harvest in such circumstances.

I have no wish to unduly criticise the manipulations of any of the brotherhood, the object of "our Journal" being, as I understand it, that each correspondent is at full liberty for the general good, to detail his system and experiences, be they successes or reverses, and, indeed, so far has this been carried out in "our corner" as to elicit a favourable comparison with our neighbours of the poultry and floral departments. "J. E. B.," however, expresses a wish "for any information," and I subjoin the following remarks, with the sincere hope that they may assist him "to obtain a better result for the future."

First, then, as to queens, your correspondent seems quite alive to the importance of having young and vigorous ones at the head of his stocks, and they do not seem to have been much at fault. I may here remark that I quite agree with "A LANARKSHIRE BEE-KEEPER" that queens of non-swarming colonies are oftener changed than is generally supposed. I had an opportunity of seeing in a strong storified stock of a friend last summer twelve months the queen, whose tattered wings and decrepid condition bespoke extreme old age, yet notwithstanding this the stock did remarkably well last season—a proof that this venerable monarch had been supplanted by a youthful rival.

The grand error of your correspondent, and one which is, I am afraid, too common in localities where the storifying system is neither practised nor understood, is a too limited breeding space. Even authorities are prone to fall into a like error. I pointed out before in one of the early Numbers of your new series in illustration of this, the absurd disproportion of Nutt's celebrated collateral hive, the central box, or "Pavilion of Nature" as he styled it, so circum-

scribed as "11 or 12 inches square by 9 or 10 deep," and yet the population hatched out in this puny affair was expected to fill with pure honey two end boxes of similar size besides three bell glasses. Are the many complaints of want of success with this hive to be wondered at? No ventilation in such circumstances could prevent either brood in the end boxes or the escape of swarms. By the way, with a good lengthy low entrance and fair shelter from the hot sunshine during the working season bees are themselves the best ventilators.

Need we go further for a second example than the advertising columns of "our Journal?" The familiar illustration of Messrs. Neighbour's shallow straw, so called "cottage hive," with its three bell-glasses, to the eye of the practical storifier is nothing more than a lady's pretty toy.

Is it right, nay more, humane, to cramp, and consequently impair, the energies of a good queen within the limits of a single box, keeping her wandering in despair over the combs, in vain seeking in her circumscribed breeding space vacant cells to unburden herself of her eggs? Can it be wondered at that she should, under such circumstances, quit the hive with a swarm in disgust, even although her condition be such as to cause her to drop to the ground a short distance from her hive, or, more generally, contrary to her instincts, ascend into the super and there deposit her eggs?

It must be apparent to the bee-keeper desirous of keeping his bees on the non-swarming principle, that he must afford them breeding space equal at least to what they would have received in fresh hives had they swarmed, and it would be manifestly unjust to draw a comparison of the fruits of the labours of a population hatched out in the area of one box with that of say three others.

But to return to "J. E. B.'s" case. His first-mentioned hive A, he tells us, "was located in a 14½-inch Woodbury frame hive" . . . "Supered in May with a box 13 inches by 7. When this super "was two-thirds filled, slipped in a frame or eke; and when the hive became crowded a second frame, exactly like the first, that is 3 inches deep, was introduced as before, both between the super and the stock." "In spite of the ample accommodation thus afforded, assisted by ventilation, the hive threw out a swarm on the 18th June." . . . "The bees ultimately nearly filled the top box with fine honey, and carried their combs down into the inserted frames, but the total yield of honey did not exceed 32 lbs."

The cause of the escape of the swarm, and the short yield of honey from this stock, is solely attributable to over-enlarged super and limited breeding space. To aid in avoiding brood 4 inches is deep enough for a full width super, unless the space can be given gradually as in Mr. Fox's most ingenious "adjuster-hive," but still that hive and the plan of eking supers are open to the objection of less or more unfilled comb, completed work being always most desirable, whether the comb be for the apiarian's own table or the market. Had your correspondent placed his frames on ekes, beneath the stock instead of the super, with a still further enlargement of breeding space as required, the result would in all probability have been the retention of the swarm, and from the vastly increased body of reapers a very different honey harvest.

The management of the second mentioned hive B was somewhat similar. It was located in a still less box, 11½ by 9, and supered also too extensively "with a box the same size as the stock!" . . . "The bees were very slow in availing themselves of the room afforded them," for the very good reason they did not then and there require it, and, as was to be expected, "sent out a swarm." . . . "Two shallow boxes were successively introduced between the stock and the super, and towards the middle of July the hive was also nadired." I may hint that placing an empty box between a stock hive and an all-but-filled super is considered bad practice by the storifier, as he thereby runs the risk of the bees rifling it of its contents, possibly with the idea that it is then beyond their control, a second super is always better placed above the filling one.

The third hive C had an inferior queen, and yielded 30 lbs. of honey, its management is not stated.

I quite agree with your correspondent that in a district, such as his own, where swarms are early, the yield must con-

trast much more favourably than here in the uncongenial north, a May swarm being a rare sight I have long longed for, but have yet to see. In my experience of the two systems the swarming and the storifying, the latter has invariably been the most pleasant, least troublesome, and decidedly (from the greater yield of the finest comb) by far the most profitable. In a poor year swarms yield nothing, but require feeding, and the year is poor indeed that a well-handled depriving-hive does not make some return; in a good season the gain is proportionately great.

In a cold wet summer the immense population of a strong storified stock keeps up an invariably high temperature, and breeding goes on uninterruptedly; when odd fine days occur the amount of honey then collected is amazing; indeed, to look on such a colony in full operation on a warm day to the enthusiastic apiarian is a sight most pleasant to behold, while, during similar cold backward weather the inmates of a half-filled box, continuing to swarm, instead of increasing in a similar ratio, have enough to do to keep up a sufficient temperature for comb-building.

I recollect of calling on an old farmer (a very experienced bee-keeper of the old school) during one of the late bad seasons, and in passing through his garden asked him how his bees were getting on, he told me he was feeding his swarms to keep them alive. I then put the question, How, he being in a much better locality and only three miles off, I should be getting from while he was giving to his bees? He seemed incredulous. I was only quizzing him. I invited him to come and see. The genuine delight of the old man on inspecting and carefully weighing between his hands a handsome octagon super just taken off, and his attempts to raise the high pile of octagon boxes from whence it had been removed, the greatest bee marvel of his life, was quite a treat to its owner.—A RENFREWSHIRE BEE-KEEPER.

#### BEGINNING BEE-KEEPING.

I DESIRE to attempt bee-keeping, and would feel obliged for some information as to how to proceed. I have commenced by buying a swarm of the 1st of May of last year in a common straw hive.—YORKSHIRE.

[Payne's hives are very good, and may be obtained at a moderate price of Messrs. Neighbour, 149, Regent Street, and 124, Holborn. We prefer them somewhat larger than Mr. Payne recommends.

If you want to increase your stock by swarming you must not put on a super. If, on the other hand, you wish to get honey and would prefer purchasing what swarms you require, a full-sized super should be put on in April. Do not attempt to transfer the bees to another hive.

A plug of hard dry wood should be tightly fitted into the upper end of each glazed pipe, and fixed with white lead. To this should be screwed a wooden platform of sufficient size to support the floor board (which should be of wood, not stone) and hive without risk of a capsizing. Let the hives face any point from south-east to south-west, but when once fixed never vary their aspect either summer or winter. Neither must you remove the milk-pan, which is quite as necessary for protection from the summer's sun and showers as from the winter's rains and snow.]

#### BEEES IN A GREENHOUSE.

I HAVE a greenhouse with a glass roof and front, south aspect, and a glass end with a full east aspect. May I use the eastern end of the house for a bee-house, making a sufficient entrance between the bricks for each hive—say three?

I am only a young bee-master; having bought two stocks last autumn, I wish to work them this summer on the depriving system, and I also wish to increase them to four stocks this season. Can I, after they have each thrown off a swarm, cut the hole in the top of the straw hive, and affix an adapting-board with super, and so obtain some honey this season from the stock hives, as well as from the swarms, should they be early enough? or must I wait until the second swarm comes off, if I find there is a probability of a second swarm coming?—W. H. P., Oxford.

[We have never known bees kept in a greenhouse, and it

would, therefore, be quite an experiment; still it is one that we should have no hesitation in trying in such a house as yours, and with little doubt of its success, if the hives be shaded in summer.

It is generally rather difficult to obtain both swarms and honey in the same season; but we should begin by putting on small supers (to contain, say 6 to 8 lbs. each), in April. These will have little, if any, effect in delaying swarming, and may very probably be filled. Moderate supers may possibly be obtained from the first swarms, if the season be a good one, and you may also put supers on the old stock as you propose, but these cannot be relied on to prevent the issue of after-swarms. Should any such result, their stores may be appropriated at the end of the honey harvest, and the bees united to those stocks which are intended to stand the winter.]

#### RANCIDITY IN BUTTER.

AMONG all your correspondents who have written upon the subject of rancid butter, I do not see that any has suggested a remedy which I have found efficient. I always when setting the milk put into each pan a pinch of nitre (refined saltpetre); also in winter put water just sufficient to cover the bottom of the pan, and in summer cold water. I have continued this system for many years, and my butter is, and always has been excellent.—G. A. E.

#### OUR LETTER BOX.

RUMKIN BANTAMS (W. B. J.).—Your Bantams, about the size of Partridges, without tails, round as balls, hens buff and rose-combed, cock orange red, are what were called "Rumkin" Bantams, and were far more common years ago than they are now. They have always been considered excellent layers.

CREVE CŒURS (J. Marsden).—Write to Mr. Baily, 113, Mount Street, Grosvenor Square, stating to him what you require to convey to America.

EXHIBITING ONLY ONE GAME HEN.—"Y. B. A. Z.," in your impression of the 28th ultimo, in his endeavour to enlighten the minds of others, says:—"Gradually it has become an established rule to limit Game hens to one. Bradford has set the example in all the breeds." Now, the same thing has been carried out by this Society since 1861. If "Y. B. A. Z." will send me his address I shall be glad to furnish him with prize lists and catalogues for 1861-2-3-4.—WILLIAM IRVING, Secretary, Halifax and Calder Vale Agricultural Association.

EGGS AFTER A FREEZING TEMPERATURE (Blue Minorca).—When water freezes eggs will chill, and, if you were to break one, you would find a partial fusion of the yolk and white. They spoil without pickling in such weather as we have had.

FOWLS IN A CONFINED SPACE (Delta).—Your feeding is good; but one sod of growing grass is worth a dozen Cabbages for the health of fowls. You will find ground corn, twice per day, more economical and more nourishing than whole corn. The golden rule of feeding is to give so long as they will run after it, and never to allow a morsel to lie on the ground. They are discreet animals, and know when they have enough.

UNMATED POULTRY (J. C. L.).—All poultry lay at a certain age (being in good health and condition), in obedience to the law of nature, whether there be a male with them or not; but it does not increase their fecundity to withdraw him. The period at which Ducks begin to lay is a question of condition, after eight or nine months. The second year is generally the best. The Aylesbury lay soonest. Greaves promote laying. Many lay in the winter, especially the Aylesbury. You may safely set the eggs after a week.

FEEDING FOWLS FOR EXHIBITING (Amy).—Ground oats, mixed with milk, are the best food; if the bird is low in flesh, and time presses, melt some suet, and add to it. The out-growing spur is a disadvantage. It is not a disqualification; but, if two birds were in close competition, it would turn the scales against the bird.

M. DE SORA'S POULTRY ESTABLISHMENT (Chanticleer).—It is said a man fished in the Seine for gudgeon with such uniform want of success that he wrote a book proving that the fish in question was as mythological as the phoenix and salamander. We have sought M. de Sora all over France, and we believe he is either a myth, or has effectually concealed himself under a "nom de plume."

POULTRY CLUB (E. H.).—You are mistaken in supposing we are partisans of any party in the poultry world. We endeavour to hold an even balance, and an impartial hand. If the Poultry Club be for the good of the pursuit, we wish it all success. We cannot tell you how many remained at the Club meeting at Birmingham, when the vote of censure was passed on the judges. We only know Mr. Fowler wrote us that he and many more had left before anything of the sort was mentioned.

LIGURIAN BEES (C. W., Kingsland, Shrewsbury).—Write to T. Woodbury, Esq., Mount Radford, Exeter. We shall be glad to receive the contributions you refer to.

STEWARTON HIVES.—Messrs. Neighbour & Son inform us that we were wrong in stating that these hives are not to be purchased in London. They have them at their shops in Regent Street and Holborn.

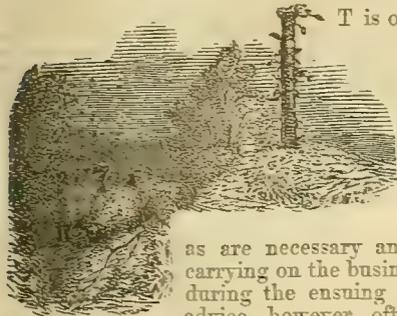

PIGSTEY (W. L. L.).—Any carpenter can construct one, and, if made of wood, the frame jointed, only resting on a row of bricks, not fixed to them, and the roof covered with asphalt felt, it could be readily moved.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 51.2°, and its night temperature 33.3°. The greatest heat was 75° on the 27th, 1830; and the lowest cold, 14°, on the 25th, 1850. The greatest fall of rain was 0.60 inch.

GARDEN IMPLEMENTS.

It is often recommended to take advantage of the long evenings and generally less busy days of the winter, in taking stock of the garden, and looking up such things as are necessary and convenient for carrying on the business of the garden during the ensuing season; and such advice, however often repeated, can scarcely be over-estimated.

In the first place, it is advisable to decide at once what alterations, improvements, and transplanting are to be carried out; then to ascertain as nearly as possible what seeds, plants, &c., will be required; then, again, to look over the stock of tools and implements, to see that they are in good repair, and to ascertain what additions should be made to them. It is of the utmost importance where neatness and expedition in performing the work of the garden is desired, that the workman should be supplied with proper tools, and these in good condition, for, however true it is that a good workman never finds fault with his tools, it is equally true that any workman, whether good, bad, or indifferent, will perform his work better with a good tool than with a bad one.

Now, we often meet in gardening books with reminders in reference to planting, altering, sowing, &c., but as far as my own experience goes, I have met with very few instructive articles relative to garden tools. Why they are so seldom mentioned, is certainly not because the subject is of less importance than those above named, for I have known instances where various tools and implements of somewhat costly make were lying idle, or hanging up in the tool-house with rust eating into the metal, and damp mouldering in the woodwork, because no use could be found for them, while really useful implements were sadly deficient. Curious as it may appear, I have seen various implements, including a costly garden engine, rotting away in a tool-house, while men were digging with stumps of spades, either broken or worn away until scarcely enough was left to turn up 3 inches of soil.

This would show that there must have been great neglect or want of judgment in selecting tools in the first place, and though such may be extreme cases, it is not improbable that there are many to whom a few useful hints would be acceptable, especially young gardeners, who are sometimes apt to be taken by the appearance of some "new-fangled" machine, which, after all, is found to be simply a trap to catch the unwary. There are various "patent" implements put before the public, some of which only increase the labour, while others are merely simple and effective implements, complicated and spoilt. I could name several such that I have tried, but it will

be less invidious to do my best to show what implements would be most useful in the garden, pointing out the uses of them, and giving such reasons for selecting them as I hope will be deemed satisfactory.

The only book in which tools are properly arranged and classified, so far as I am aware, is "London's Encyclopædia of Gardening." There we find them classed as tools, implements, and instruments; the latter being chiefly for operation—as the knife, the shears, the scythe, &c.; implements for application—as the watering-pot, garden-engine, lime-dredger, &c.; for adaptation—as the flower-pot, the rustic vase, the stake, &c.; while tools are chiefly for breaking into and turning up the soil. This arrangement of tools, the only one with which I am acquainted, is very good, but is not what I propose entering into at present, my object being to give a list of tools suitable for villa gardens, to point out their uses as far as practicable, and afford a few hints for selecting the most serviceable kinds. This I would wish to do in a manner that may be useful to gardeners and their employers—to the latter, by showing what tools are really necessary in the garden, and to young gardeners by advising them to prefer such tools as are really serviceable, and not be led into purchasing tools and implements that present great attractions to the eye, but are found to be an incumbrance as far as their use is concerned.

I am far from recommending any gardener to limit his stock of tools to such as are in general use. On the contrary, I would advise him to obtain all he is likely to have need of, provided they are of serviceable kinds. Yet it is well not to carry the number too far, for the reason that in many gardens a very limited number will be sufficient for all purposes, and beyond these it is not worth while to encumber the place. This, however, is a question apart from my present purpose, which is to give the names and uses of various tools in a way that I hope will be useful.

The following are such as are required in most gardens of any pretensions:—

<p><i>For removing soil, &amp;c.</i> Wheelbarrow. Handbarrow.</p> <p><i>For carrying and applying water, &amp;c.</i> Waterbarrow. Garden engine. Syringe. Watering-pot.</p> <p><i>For operating on Grass, &amp;c.</i> Mowing machine. Scythe. Shears. Edging-iron or razor.</p>	<p><i>For operating on trees, &amp;c.</i> Saw. Axe. Bill or hatchet. Shears. Knife.</p> <p><i>For turning and breaking into soil, &amp;c.</i> Spade. Fork. Shovel. Pick. Mattock. Hoe. Rake. Trowel.</p>	<p>Crowbar. <i>Miscellaneous.</i> Roller. Ladders. Turf-beater. Turfing-iron. Line. Measuring-rod. Dibber. Sieves. Hammer. Pincers. Brooms. Baskets. Brush. Dredgers. Fumigators.</p>
---	--	---

The following I consider materials generally used in gardens of ordinary extent:—

Nails.	Pots.	Soil.
Shreds.	Nets.	Lime.
Matting.	Mats.	Sulphur.
Sticks.	Labels.	Tobacco, &c.

The above are, as far as I can call to mind, nearly all

the implements, &c., that are in general use, or are likely to be required in an ordinary villa garden; but of nearly every kind of implement named there are different varieties which it would be worth while to notice in order that the best might be selected. For instance: to begin with

IMPLEMENTS FOR MOVING SOIL, &c.

**WHEELBARROWS.**—That kind in general use about London I consider to be very well contrived, on account of being fitted with a portable top. This allows of a great deal of light rubbish, leaves, or litter, being placed on it, and by taking off the top, the barrow is handy for wheeling gravel or other heavy material. There is a kind of wheelbarrow in general use in the northern and midland counties, which, although not so light and handy for garden-use, is more so in the greenhouse or among potted plants, on account of having a flat bottom, which is convenient for plants or soil, and makes a very good portable potting-bench. I have frequently found it very useful in this way; pots are filled with soil ready mixed, and placed near the pipes in the hothouse to warm, the barrow is next drawn in, and Pines and other stove plants can then be potted without removing them out of the house. Even in the greenhouse, supposing there is no stove or hothouse, potting may be done in frosty, snowy, or rainy weather, without having to carry the plants out, and much injury to these may thus be prevented. I have seen a wheelbarrow similar to that in common use about London, having two wheels fitting closely, or nearly so, to the sides of the barrow, nearly in the position where the ends of the axle are seen in the one-wheeled barrow. This arrangement, of course, makes the load lighter for wheeling. It is also well for turning and shooting, but for various reasons it is not so generally useful as the one-wheeled barrow, not the least being, that it cannot be conveniently used on boards or planks, and then the extra expense is scarcely compensated for by any advantage that I can perceive. Various contrivances have been brought into use at times for carrying plants in pots. Barrows have been made with one wheel, with two, and with three, or even four wheels, but all are more or less objectionable—the one-wheeled barrow on account of the impracticability of obtaining a level surface while the barrow is at rest; and when in motion the two-wheeled has the same fault. This is obviated in the three and four-wheeled barrows, but these are not so easily moved about into the shed or greenhouse. Where more than one man is employed, a barrow without any wheels will, probably, be most handy, so that we pass on to

**HANDBARROWS.**—These are chiefly used for carrying plants from one place to another, but a handbarrow requires two persons to use it. Plants are thus moved about without the jolting and shaking they would receive in the wheelbarrow. The handbarrow may also be used as a potting-bench inside the stove or greenhouse. A handy size of one for ordinary use, would be about 4 feet long, exclusive of the handles, and about 2½ feet wide. Something of a rail round the sides would make it more convenient for small pots or holding soil; but when chiefly used for large plants, it would be better without it. About 18 inches would be high enough, for I think it would be a mistake to make it any higher. I have seen them higher, but such seem to me to be clumsy, compared with those that have shorter legs. If the handles are a little bent they look better.

Small trays or handbarrows without legs are sometimes used to move large plants about; the plants are tilted on one side, and one edge of the tray thrust under the plant or pot; the plant is then drawn on and easily lifted about with less fear of breakage than would otherwise be the case.

Having made some alterations here lately, and the nature of the ground being such that the wheelbarrow could not well be used, I have made use of a two-handled box, the box being about 18 inches deep, the same in length and breadth. This is conveniently fitted with two handles so as to be carried between two men in the manner of a handbarrow. With this some scores of tons of sand, gravel, peat, loam, &c., have been moved about, and that without making the ruts and marks that a wheelbarrow would. I am aware that there is nothing new in the idea, as similar contrivances are in use; I merely give the hint, as such a box may be easily constructed by any one who can handle a saw and hammer,

and it will be found useful in muddy weather as a cleaner method of moving soil than the wheelbarrow. Such barrows as these require two persons to work them, consequently, where but one man is employed there will be little use for them. In that case, a flat-bottomed wheelbarrow will be found most useful.—F. CHITTY.

(To be continued.)

[We purposed publishing the foregoing portion of Mr. Chitty's communication last week, but withdrew it upon receiving the painful intimation that death had suddenly removed him from among our helpmates. Since then we have received the following from his employer:—

"Gentlemen,—It is with sincere regret I announce the death of your able contributor, Mr. F. Chitty, after only three days' illness, and at the early age of thirty-three. Although he has been in my service but a little more than two years, yet the confidence I had in him was unbounded: He was in all things a trustworthy and faithful servant, and respected by all who knew him, not only for his ability as a gardener, but for his kind and unassuming manners. He was ever ready to impart and to receive any information connected with his profession, and though he has been here but so short a time, yet will he be much missed by the lovers of horticulture in this neighbourhood. He has left a widow and five young children (the oldest not yet nine years old), to lament his loss, and totally unprovided for. I, therefore, feel no hesitation in appealing to the kind feelings of the readers of your Journal for some assistance for the poor widow and children, feeling sure that all who have read his sound practical articles on horticultural subjects, will contribute something to alleviate so distressing and deserving a case. Will you kindly consent to receive any contributions that may be forwarded to you?—I am, &c., THOMAS WEBLEY, *The Uplands, Selby Oak, near Birmingham.*

"P.S.—Should any of your readers wish for further information, I shall be happy to give it. I enclose a list of contributions already forwarded to me.—T. W."

Mr. P. Webley .....	1	1	0				

We shall readily receive any contributions to this fund and forward them to Mr. Webley, whose generous testimony to the merits of his late servant we heartily sustain. Mr. Chitty was always to be relied upon, and though well skilled never gave a hasty opinion; though very unassuming he was firm in sustaining what he felt was the truth. We confidently ask our readers to aid in helping the widow and orphans of a man so worthy in every way.—Eds.]

THE MODERN PEACH-PRUNER.

No. 6.

TRANSPLANTING.

THE time and mode of planting a young Peach tree may now be considered. Very much of the after-success of the tree depends on this being rightly done; therefore it is a more important operation than at first sight might appear.

A tree may either be reared in our own gardens, or it may be purchased at some neighbouring nursery. In either case it need not be long out of the ground; and this constitutes a case differing somewhat from that in which trees are received from a distance.

In the first supposition, if the tree has been trained against a warm wall, with all its branches and shoots fairly exposed to the sun, then it will be in first-rate condition for transplanting. By taking care of the all-important spongioles, by replanting at a short interval of time carefully in a suitable soil, and on a mild and genial day, no check will take place, and root and leaf will soon resume their reciprocal functions. Supposing the tree not to have been reared under such favourable conditions, but still not to have been more than a few hours out of the ground before replanting, it may then also be depended upon, care being taken not to mutilate the roots, which is the main point, to continue its growth without much check.

In both these cases early planting is recommended. The leaves being still on the branches, though they droop when the tree is lifted, they will soon recover their state of tension, and be ready to receive their daily supply of sap from the roots, which, being unamutilated, will also shortly recommence their proper functions.

We may even expect that some new cellular tissue will be added to the spongioles by reason of this early change of place before winter comes on; for if transplanting be done in October, there is at that period much latent and unex-

pendent earth heat, which heat is absolutely necessary to enable the roots to extract from the soil the food proper for the tree. Besides, the leaves being also uninjured, begin to elaborate the fresh sap, and so increase that reserve of cambium which some think is dispersed in the interior tissues of the tree, for the purpose of preserving its vitality during the trials of the winter season. This seems a reasonable supposition, and an explanation of the reason why early transplanting is so beneficial when properly performed. Our French neighbours are not unaware of this, for at Montreuil November is considered to be the proper month for planting; but then there is, no doubt, as much heat in the earth during November in that sunny spot as there is in our cloudy land during October. When, however, trees are received from a distance the case is different. The leaves cannot be expected to recover, and no advantage can be obtained by planting so early. Provided, then, care is taken to anticipate the extreme cold of November, early in that month is a suitable time.

Should early planting be impossible, it is not a bad plan to wait till mild weather sets in in February or March. Dry, windy, or sunny days are unfavourable for transplanting, on account of the amount of evaporation they promote in the tree; for even when the trees are without leaves, evaporation takes place through the bark, and if there be no corresponding absorption of moisture through the spongioles to supply this waste, they being out of the ground, the tree suffers. A mild, rather damp day is then the best for the operation we are describing.

Of course, young trees are by far the most easy to remove. Whenever large fruit trees are transplanted, men of great experience in such matters tell us that the success of the operation depends mainly on the quantity of earth removed with the roots. They also recommend such large trees to be removed in a growing state, because the moisture remaining in the earth adhering to the roots is at once assimilated as food for the tree. But when the earth is cold and the tree dormant, this moisture surrounding the roots is not absorbed by them, nor can it be. The result is that it has rather a tendency to rot the roots, more especially those portions which have been injured. There is no doubt that the whole subject of transplantation is a very interesting one, and deserves careful study.

The process of planting is as follows. Having chosen the young Peach tree for its clear and polished bark, the proper distance to place the stem from the wall is about 6 inches. Some say 4 inches, but on the authority of the best cultivator in England it is stated at 6.

If the tree is to be planted where no other has stood, a hole twice the diameter of the roots when spread out is sufficient. If otherwise, the old soil must be removed, and the opening made much wider. A piece of pavement or a wide flat stone is generally placed under the tree to prevent the roots striking downwards. The old monks always did this, and famous gardeners they were. Roots grow in tiers; therefore the lowest tier must be carefully spread out all round, occupying the ground without crossing each other if possible. Fine pulverised soil must be shaken over this lowest tier, but no manure must ever touch them. Never tread on the roots, as so many do, and never move the tree up and down, which absurd practice has the effect of doubling up the fine ends of the roots underneath. Break down the sides of the hole for fresh earth, and place pieces of turf cut from a rich field for the roots to run into at their first start. Then the upper tier of the roots should be spread out fanwise in the same careful way, and equally covered. When the earth is filled in to three-fourths, water freely in light soils, and less in firm ones. More water in any case should be given to trees planted in the spring. Mulching at the time of transplanting is an excellent old custom; it excludes frost, and lessens evaporation.

Deep planting is an evil in the case of fruit trees. No tree should be planted deeper than it formerly grew, or it will be in danger of having its roots stifled for want of air; and this will cause the tree to languish, till, by an effort of nature, it pushes out roots nearer to the surface for air. Thus delay will arise instead of progress. It is by far the best, especially in firm and retentive soils, to plant the tree so that a small mound is necessary to cover the roots. Let these be within an inch or so of the surface—the ground

will always settle. Deep planting should always be avoided. If done, the tree makes no spring growth, but grows late in the year—exactly the reverse of what we require.

Some trees are notoriously more difficult to transplant than others. Some place them in this order as to risk—first the Cherry, then the Apricot, and then the Peach; but if carefully done there is little real danger. We should never forget to secure transplanted trees firmly to the wall, for fear of high winds.

In the case of the Peach there is always a certain danger lest the buds which have remained latent during the whole of one season should not break at all; therefore the tree may be headed down soon after it is planted, as a rule. Nevertheless, could we secure the roots intact, there would be little need of this. If the tree has been grown in a pot the roots ought to be entire, and having shaken out most of the ball of earth, the roots should then be spread out well, and no shortening ought to be required. This, of course, presupposes that the tree while in a pot has been regularly trained for the particular form required.

On the whole, it cannot be said that trees which have been more than three years in pots are the best suited for planting out. The roots become strong, and have an inward twist, which makes it perilous to endeavour to open them out well. A year or two may be passed with very great profit if the trees be well looked to, and pots changed as the roots fill them. Up to three years this may be done; and certainly the way that vertical cordons, three years established in large pots and full of fruit-buds, both grow and bear the season after they are planted out would astonish those who depreciate pot-cultivation.—T. C. BRÉHAUT.

#### STRAWBERRIES IN DORSET.

THE Strawberry plants here are beautiful, and have wintered well, as can be seen by any of your readers, who live near here, if they please to look in. John Powell is first-class as a plant of dwarfish habit. The fruit last year was excellent. Sir Joseph Paxton is a charming plant; and, with its fine bold crowns, now beginning to show its fruit-buds, is a fine verdigris green with stout foliage, uninjured by this severe winter. President, also, is a nice, strong, hardy plant, and defiant of winter. They are two of the best, as plants, of later-raised novelties, to suit and please me. Eclipse is also hardy and healthy, and, I fancy, it is the highest flavoured and best of all the early Strawberries.

The first-rate Queen-growers of this county, who seldom fail with the Queen, failed signally last year. They were loud in the praises of Wonderful especially, Rivers's Eliza, and Empress Eugénie. These three and the Frogmore Pine and Royal Hautbois are my pentateuch of dependence and excellence. I have extra-fine plants of the Scarlet Pine in the same place as La Constance used to stand. It is treated in the same way. It is a delicious first-class Strawberry, of quick establishment, and of a most hardy and robust constitution. As it does not always set its fruit well, I have not recommended it; but it is well worth a trial. You would find no trouble with it as a plant.—W. F. RADCLYFFE, *Tarrant Rushton, Blandford.*

#### MY PLANTS,

#### AND HOW AND WHERE I FOUND THEM.

"Earth is now green, and heaven is blue;  
Lively spring, which makes all new,  
Jolly spring doth enter:  
Sweet young sunbeams doth subdue  
Angry, aged winter."

It was in the spring of 1863 that I found myself located in a small village in North Staffordshire. My husband had accepted the offer of partnership with a medical gentleman in that county; and it was with low spirits and a large amount of fearfulness that I left the Great Northern Station, and found myself whirling onwards, onwards, to what I feared would be a mass of smoky chimneys and furnaces; for I am ashamed to say that my idea of Staffordshire was embodied in that well-known expression "the Black Country." Manufacturing towns and smoke were my abhorrence. You may therefore fully realise my mental pain. I, a lover of

nature and beauty, of the pure air of the country, of all sweet and harmonious sounds, feared a lifetime of incarceration amongst blackened houses, the noise and din of machinery, and the anxious and careworn faces of the operatives. There was no music for me in the incessant hum, and clash, and clash of the mechanical motions of the factory. The melancholy poetry which one may weep out of the thinly clad, consumptive, and starving workers had no charm for me. Upon their brows I had seen written, as with a finger of blood, "Slaves to the Mammon of Unrighteousness," and I had wept silent tears as I saw them sinking, slowly but surely, into an early grave.

It has always been my delight, and almost a necessary part of my existence, to wander free and unrestrained, seeking the health and purity which God so freely scatters over hill and dale, and in the secluded spots where dwell some of our sweetest and tiniest favourites. But I will tell you how this gloomy foreboding, like many a dark cloud o'er life's pathway, passed away. On and on sped our train—an express, by-the-by, which is never favourable for giving travellers a very close insight into the botany of the country through which they pass. How delightful, how reviving, then, was it to that despairing lady in the first-class carriage to find, after leaving Derby and approaching the termination of her journey, that the scenery became most wild and romantic, the country apparently favourable for Ferns, and everything indicating a luxuriant vegetation! The rugged and picturesque hills and vales of Oakamoor charmed me, and I gave utterance to my inward joy in exclamations which no doubt made my fellow passengers believe that I was somewhat beside myself. My husband, who has a pet theory of his own that "every one is mad upon some point," of course immediately brought the subject upon the *tapis*, and concluded his oration by bringing forward at the same time his wife as an apt illustration—mine was a Fern mania. Denial was impossible. I felt it myself, and the learned doctor was left in the full enjoyment of his thesis; for we all know that

"None but a clever dialectician  
Can hope to become a great physician;  
That has been settled long ago.  
Logic makes an important part  
Of the mystery of the healing art;  
For without it how could you hope to show  
That nobody knows so much as you know?"

Woman like, however, I must have an argument, particularly as we had a few minutes still to spare ere we arrived at the station.

I proposed as a query  
In place of his theory,

Whether my monomania had not commenced when I married *him*? We had not satisfactorily settled that knotty point when the diminishing speed of our train, and soon after the words "Froghall," "Froghall," uttered in the Staffordshire dialect, put an end to our repartees, and reminded us that we had several miles of our journey to accomplish by road, and that it was necessary to stow away the bairns and luggage.

I will pass over the usual bustle of settling down in a new house, the necessary amount of breakages and discomforts ere everything gets "fettled" up, which more or less falls to the lot of all under like circumstances; the curious eyes which scrutinise, and the more curious remarks which are made upon newcomers into a small and self-satisfied village in an inland county—all this we passed through with the usual and provoking nonchalance of old travellers.

It was about three weeks after our arrival in T—that a patient came in. It came out in the course of conversation that he was the village gardener, and I immediately questioned him as to the nature of the surrounding country and its facility for Fern-collecting. To my surprise he began smiling, but he apparently apologised for the same by explaining that he had just come from that omnium gatherum the village shop, where he was fairly pounced upon by several of the customers with queries as to "what the new doctor's wife was allus a getting and carrying home them green things for. She seems wholly taken with things we wouldn't stoop to pick, much more plant 'em in our gardens. A handsome Gillyflower now would be something like, but not such rubbish as 'Farns,' which grow

everywhere." One woman more sapient than the rest said, "I know what she does with 'em though, her husband's a doctor, and she gets 'em to make 'yarbe' tea off, to be sure. "Aye, sure enough," they all said; "missus you're gottin un now." So it was agreed in the self-instituted committee that the weak-minded writer of this was a collector of herbs. The gardener finished his recital by smilingly telling me that I was the talk of the place. "You see, mam, we're so accustomed to see these sort o' things that we doant notice them. Maybe they doant grow where you comes from; they says you'r a fine London lady, and mayhap they doant grow thereabouts?" However, in spite of culumniators and many side looks as I passed through the streets, I still indulged in my "yarbe"-gathering propensities. Perhaps with Dr. Seraphino they mentally ejaculated—"May the Lord have mercy on your position, you wretched, wrangling, culler of herbs!"

A year passed away, and as spring came round again I eagerly sought my old favourites and their haunts, from which through unforeseen circumstances I was removed soon after. I propose, for the amusement of those who are like myself "Fern-mad," to give a sketch of pleasurable excursions amongst woods and rocks, of prying into wells and under overhanging grasses under a broiling sun or in a pouring rain, in search of these children of the earth; for it will serve to show how much real enjoyment there is in a country walk in all seasons and all weathers.—ALICE.

### THE ROYAL BOTANIC SOCIETY'S FIRST SPRING SHOW.

This was held on Saturday the 18th, and notwithstanding a due east, and exceedingly keen wind, was honoured by the presence of H.R.H. the Princess of Wales; and well worthy was the exhibition of such distinguished patronage, for never do we remember having seen Hyacinths in such perfection—the spikes so fine, the colours so rich and varied—as they were on this occasion. They constituted the chief attraction of the show, but not the only one, for there were the gay early Tulips, Roses, some almost as good as may be seen in summer, Cyclamens, Primulas, Cinerarias, and Camellias, the whole making a display of colour such as one could hardly expect at a season when Nature is only beginning to throw aside her winter dress.

Year after year Mr. Wm. Paul and Messrs. Cutbush have contended with varying success for the chief honours with this flower, and after many a hard-fought battle it was no surprise to find them again in "the tented field." Mr. W. Paul was first both for twelve and for a collection with magnificent spikes having a luxuriance, combined with a compactness of growth and richness of colour, that at once struck the observer. The twelve consisted of Solfaterre, Von Schiller, and Macaulay, remarkable for their brilliant colouring; King of the Blues, splendid; Garrick, Grand Lilas, Prince Albert, large for that kind; Grandeur à Merveille, and Van Speyk very fine; Alba Maxima, Tubiflora; and Ida, yellow. Messrs. Cutbush's twelve were also very fine. They consisted of La Prophète, Von Schiller, splendid; Macaulay, Florence Nightingale, Emmeline, Snowball, remarkable for its large bells of great substance; Mont Blanc, Marie, a splendid spike; Baron Von Tuyl, Garrick, Grand Lilas, and Mimosa. The collections from Mr. W. Paul, comprising 125 pots, and from Messrs. Cutbush 100, included nearly all the best kinds of the various colours, and it would be tedious to enumerate them. Lord Palmerston and King of the Blues, which, relatively speaking, may still be considered new, fully maintained their high character, the white eye and clear blue of the former and the fine deep blue of the latter rendered them conspicuous. We did not, however, observe either the rich crimson red Josephine or Robert Fortune. Among Reds, Queen of Hyacinths, Von Schiller, Pélissier, Howard, and Solfaterre were conspicuous by their high colour; of Whites the best were Queen of the Netherlands, Mont Blanc, and Alba Maxima; Grandeur à Merveille, bluish; Fair Maid of Denmark was also very pretty. Of Blues, in addition to those already named, were excellent spikes of Van Speykstoren Bloksberg, Admiral Coligny with very large bells, and Couronne de Celle; whilst in those shades approaching black

there were Feruck Khan, Prince Albert, Havelock, and Mimosa. König von Holland, Ida, and Duc de Malakoff were the only yellows, and Haydn the only mauve.

In the Amateurs' Class the only exhibitors were Mr. Young, gardener to R. Barclay, Esq., Highgate, and Mr. Wheeler, gardener to Sir F. H. Goldsmid, Regent's Park, who were respectively first and second, and the spikes were a great improvement on those shown last year.

Early Tulips were exhibited by Messrs. Cutbush and W. Paul, both in the class and in numerous collections, the former taking the highest award in both cases with very large flowers. The kinds shown by Messrs. Cutbush were chiefly White Pottelbakker, Proserpine, Fabiola, Couleur Cardinal, a fine reddish scarlet, Keizerkroon, and Duchess of Parma, very showy, Tournesol, and Vermilion Brilliant. In Mr. Paul's collections, in addition to several of the above, we noticed Roi Pepin, a very showy white and red, Archduc d'Autriche, a very fine crimson and yellow, and Cerise Gris de Lin, lilac rose, margined with yellowish white, very distinct in colour. Van der Neer was also a good purplish violet.

Roses in pots came from Messrs. Paul & Son; conspicuous among these was John Hopper, which stood alone in the fullness of its beauty, and dazzling in colour. Madame Falcot and President were also very good. Mr. W. Paul contributed three excellent boxes of cut blooms, among which were excellent examples of Gloire de Dijon, President, George Paul, Madame Victor Verdier, Lord Macanlay, Rev. H. Dombain, Marquise de Foucault, Senateur, Comtesse de la Barthe, a pretty yellow Tea, Safrano, and Alba Rosea, very pretty and delicate in colour.

Cut Camellias in fine condition were numerous shown by Messrs. Lee, Hammersmith, W. Paul, B. S. Williams, Mr. Trussler, gardener to D. J. Kay, Esq., Hoddesdon, and Mr. Todd, gardener to Sir C. Isham, Bart., Lamport Hall; and Mr. Bull sent a collection of very good specimen plants, among which the most remarkable were Mrs. Abbey Wilder, Raffia, and Valtevarado.

Collections of flowering and fine-foliaged plants were exhibited by Mr. Wheeler, Mr. Young, and Mr. B. S. Williams. Among those from the latter were Hedera Hookeri in fine bloom, and a fine plant of Gleichenia semivestata; while Mr. Wheeler had Thyracanthus rutilans and a well-bloomed specimen of Azalea Broughtoni, besides Marantas, a Dicksonia, and other plants with ornamental foliage, Deutzia, Cytisus, &c. Mr. Williams likewise showed a small collection of new and rare plants, chiefly consisting of Agave, Yucca, and Dracena, together with Beaucarnea stricta; also a new Azalea, Souvenir de Prince Albert, rose, broadly-edged with white, and Pandanus Linnæi. From Mr. Bull came the collection of Aucubas fully noticed in our Floral Committee report of last week, the female Aucuba and A. himalaica in fruit, Camellia Prince Camille, a finely imbricated red; Asplenium myriophyllum, from South America, with very graceful finely-divided fronds; Anthurium augustioranum; Aglaonema commutatum in fruit, and a double Chinese Primula with large rosy purple flowers.

Mr. Veitch sent Rhododendrons, Princess Helena and Princess Alexandra, both of them pretty hybrid varieties apparently obtained from Jasminiflorum, partaking of that character, but having a long tube, in Princess Alice, bright rose, the flower a rosy blush; whilst Princess Alexandra is pale blush with orange stamens and very pretty.

Messrs. E. G. Henderson sent Aucubas in flower and berry, and the male plant of the variety picturatum, Rudgea leucocephala with large green foliage and terminal clusters of pure white flowers; excellent collections of Cyclamens, including several very pretty varieties of persicum, Fern-leaved and Anemone-leaved Chinese Primulas, and a pretty variety called carminata splendens with salmon rose flowers. Mr. Todman, gardener to R. Hudson, Esq., Clapham Park, exhibited some good double and single Chinese Primroses; Mr. Weatherell, Finchley, Primulas and Cinerarias in excellent bloom; Mr. Paul, a collection of Crocuses and Narcissus, and some pots of Lily of the Valley, very fine both as regards flowers and foliage; Mr. Young, Tulips; and, lastly, Mr. Laing, Twickenham, two plants of the common Aucuba, bearing an abundance of its beautiful coral red fruit, and in this state forming highly decorative objects. There can now be little doubt that when the male plant

becomes more widely disseminated, the Aucuba will be as much valued in ornamental gardening for its fruit as it now is for its foliage.

## ROYAL HORTICULTURAL SOCIETY.

WEEKLY SHOW, MARCH 18TH.

ON this occasion Messrs. Lee sent a very handsome specimen Camellia Madonna, also some beautiful cut blooms of Countess of Orkney, Jenny Lind, Leeana superba, and others; Lycaste cruenta and Skinneri, Dendrobium nobile, and five standard Azaleas in excellent bloom. From Mr. Bull came Brahea dulcis, Cyripedium barbatum giganteum and villosum, Dracenas, Platycerium alciorne, a fine specimen, and plates of his new Chrysanthemum Sensation, with variegated foliage, and Verbena Popular, also with variegated leaves. Messrs. A. Henderson sent a small miscellaneous collection of spring flowering plants, including Gastrolobium, a Grevillea, Rhododendron ciliatum, &c., and Hebeclinium giganteum, with lavender Ageratum-like flowers; Mr. Harding, Maddox Street, five very dwarf and compact well-bloomed standard Azaleas for the dinner-table; the Rev. G. Cheere, Anne Boleyn Pinks; Messrs. Lucking & Greeves, similar exhibitions to those of previous weeks; Mr. Boyce, Stockwell, Chinese Primulas; and Mr. Long, gardener to Sir H. Hume Campbell, a flower of the Life Plant. Mr. Brown, gardener to Mrs. Ashton, Elmdon Hall, exhibited some fine Easter Beurré Pears from a small tree on a south wall, the crop numbering 130; and Mr. Melville, Dalmeny Park, two heads of "Improved Milan Sprouting Cabbage" obtained by crossing with Brussels Sprouts, and having the same appearance and being as compact as the latter vegetable; also a green-leaved Sea-kale, said to be easier to blanch than the purple kind.

LIVERPOOL FLOWER SHOW.—There was an excellent exhibition of spring flowers, but we must defer our report till next week.

## MUSHROOM FORCING.

As my mode of Mushroom growing with chambers underneath is somewhat different from the common mode, perhaps some of your numerous readers will be glad to know how I succeeded. Between the time of writing to you and seeing your answer, which was given in your Journal of the 28th ult., page 173, my Mushrooms had begun to appear by thousands. I then allowed the dung in the chambers to cool down as it would, and I built up a lining with a mixture of stable-dung and leaves, 4 feet high by 2½ feet wide, along the front of the beds and outside the chamber doors. I covered with straw and long dung, and the result has been that I now have Mushrooms in abundance, which for size, thickness, and flavour by far surpass all others that ever I saw grown in a Mushroom-house or elsewhere. The chambers underneath the beds form an excellent place for forcing Sea-kale in pots, from which I have cut a dish every other day since the 8th of November.—H. L.

## SUNK HOUSES WITHOUT FIRE HEAT.

IN your Journal (No. 206), Mr. Geyelin has given a plan for a sunk pit, which is most ingenious, and, I think, quite practicable. He will, however, pardon me for suggesting the following alterations. No benefit, but rather the reverse, is obtained by raising the hotbed so high above the ground. It should be level with the surface, and then the walls of the sunk greenhouse or pit need not be more than 2 feet above the level of the soil. The coping on the top of the walls should be removed, and a wall-plate, framed to the rafters, substituted in its place, so that the sashes might be drawn up or down from the outside, in the same manner, and with the same ease as in a common Cucumber-frame. Many persons, however, might object to the hotbeds at the sides. I would, therefore, suggest instead, that a sunk area 2 or 3 feet wide, reaching down to the foundations of the walls, should surround the building on all sides, to be filled with fresh stable-dung or tan, and boarded over to keep off rain. This would confer a double benefit—viz., warmth

and perfect dryness, and isolation to the walls. This manure would not be wasted. As regards damp from below there is no reason why the house should not be made as dry as the floor of an underground kitchen. The building should run north and south, and the valley roof, as designed by Mr. Geyelin, would admit the sun's rays at all periods of the day. The entrance door should be at the south end, the steps leading down to which should be provided with a trap-door, to be closed at night, and in frosty weather. The wall at the north end should be carried up to the same height as the side walls, forming a sort of parapet across the valley of the roof to protect it from cold winds. A Laurel or Privet hedge carried round three sides of the structure would form an additional screen. Any amount of ventilation may be given by means of the door and sashes. If the latter were double glazed it would be a great advantage, whilst the lowness and accessibility of the roof would at all times facilitate the application of a straw and tarpaulin cover when considered necessary. I really think a plan of this kind quite feasible, and that the temperature within need never be allowed to fall below 40° during the longest frosts. The house, of course, would only be applicable to certain purposes, but if it could be made to answer it would prove a boon to many.—ISLE OF WIGHT.

### PREVENTING THE GOOSEBERRY CATERPILLAR.

IN "our Journal" of the 22nd of March in last year I stated that I had just laid a thick coating of tan under my Gooseberry bushes, and that I had little doubt that its application for two or three seasons would, as in former instances, prove a "perfect cure" for that terrible pest the Gooseberry caterpillar. The result has thus far completely verified my anticipations. The scourge re-appeared last year, but in such diminished numbers that they were kept completely under by a little hand-picking. My crop was, of course, small, owing to the injury done to the bushes during the previous season, but all ripened well, and the bushes having now recovered their strength, I have every prospect of a good crop, which a second thick coating of tan will doubtless enable to ripen without injury from the caterpillar. Now is the time for applying the remedy, with which the surface of the beds should be covered to a depth of at least 2 inches. If the soil be heavy the tan may be beneficially dug in in the autumn: if light it had perhaps better be collected in a heap and burnt. After a couple of seasons a thin coating is generally sufficient to keep the enemy completely at bay. *Experto crede.*—A DEVONSHIRE BEE-KEEPER.

### ORCHIDS FOR GREENHOUSE.

To "W. A. O.," who requests "a list of Orchids that will flourish in a cool greenhouse," I recommend Mr. Bateman's "Guide to Cool-Orchid Growing," (Reeve, 1s.); and Messrs. Backhouse & Son's "Catalogue of Greenhouse and Vinery Orchids," which he will receive by post on sending six stamps to them at York. This latter is beyond all comparison the most valuable treatise on cool Orchids yet published; for besides a descriptive and priced list of about 240 kinds, it gives details of cultivation, derived from the experiments of those eminent growers, which are of very great practical value.

This very day twelvemonth (March 17th, 1864), I removed the following species from the coolest end of a stove, where they had passed the previous six weeks with a minimum temperature of 40°, to a cool greenhouse, where, on a shelf close to the glass, the night temperature frequently went as low as 37° and 36°, and once 34°, in the course of March and April; while, on the other hand, the forenoon sun occasionally ran up the mercury to 80° and 90°, before I put up the summer shading. The interstices between the pots were stuffed with moss, which was kept constantly damp. On this shelf they remained till the end of November, when, the temperature having descended to 35°, they were removed again to the cool end of the stove. Here they have again passed the winter; the night temperature ranging mostly between 40° and 50°, never going below the former, nor above 54°. Most have done well several very well. Calan-

the vestita failed, made only miserable little bulbs, which did not survive the winter. I remarked a fact (which Backhouse takes notice of and explains), that many of the plants showed not the slightest sign of making growth till the summer was well advanced. After the season's discipline, however, I expect they will be much earlier this spring: indeed, some of them are starting already.

These are the species in question:—

Calantha vestita.	Lycaste cruenta.
Cattleya citrina (block; made stout bulb).	aromatica.
Skinneri (made flowering bulbs).	Skinneri.
Cœlogyne cristata.	Odontoglossum citrosimum.
Cyrtocidium maculatum.	grande.
Cœlia Bauerana (flowered).	Inaleayi (flowered).
Dendrobium speciosum.	Oncidium leucochilum.
Epidendrum aurantiacum (flo. bulbs).	sphaclatum.
vitellinum.	Sophranitis grandiflora (block; flowered finely).
Lælia albidia (made very strong bulbs).	Trichopilia suavis.
anceps.	Disa grandiflora (with wetter treatment than the rest, flowered finely).
furfuracea (?)	

Most of these were small plants, scarcely mature enough to flower. On the whole I feel satisfied with the results, though the trial as to temperature was, perhaps, unwarrantably severe. I mean to repeat the treatment with them this season, only giving them a month longer in the cool part of the stove, and removing them to the greenhouse about the middle of April. I shall probably add to the number the following:—

Calanthe veratrifolia.	Miltonia candida.
Cattleya Mossiae.	spectabilis.
Cypripedium insigne.	Oncidium crispum.
venustum.	flexuosum.
Dendrobium chrysanthum.	bicallosum.
fimbriatum (oculatum).	Phajus Tankervilleae.
nobile.	albus.
Kingianum.	Rodriguezia venusta.
monilliforme.	secunda.
pulchellum.	rigida.
Lælia Perrinii.	Trichopilia tortilis.
purpurata.	Vanda teres.
Maxillaria Harrisoniae.	Zygopetalum Mackayi.
graminea.
